The necessary space for dockyard purposes is exceedingly limited at the Rock of Gibraltar, and thus, with the exception of the small area of the old yard, the area required has been obtained by artificially reclaiming the land over a considerable sea-space, of which the soundings range from low-water mark to 40 feet in depth. The total area thus created for dockyard purposes is about 64 acres. The material required for this reclamation is obtained chiefly from quarries on the eastern side of the Rock by means of a tunnel pierced for that purpose. The graving docks are three in number, alike in cross section and in depth over the sill, but of unequal lengths, to accommodate battleships and cruisers. Dock No. 1 is 850 feet in length, 95 feet in width at entrance, and has a depth of 35½ feet over the sill at low-water springs. It is divided into two portions by an intermediate sliding caisson, and is capable of docking two ships simultaneously. Dock No. 2 is 550 feet, and Dock No. 3, 450 feet in length, and of similar dimensions in width of entrance and depth over sill. All the docks will have their entrances closed by steel sliding caissons, and are lined throughout with granite and limestone. The most important dockyard buildings are the pumping-engine house, the workshops of the chief constructor's and chief engineer's departments, the naval stores and offices. The pumping-engine house will contain the steam machinery for the emptying of the dry docks, which will be capable of pumping out the contents of the largest dock, amounting at high water to 105,000 tons, and discharging into the sea in five hours. The workshop for the chief constructor's department is an extensive building, 407 feet in length and 322 feet in width. The shops of the chief engineer's department are comprised within a building of similar dimensions. The staff captain's department and other stores are comprised within buildings having a total floor-space of about 300,000 superficial feet. At the northern end of the yard are the administrative offices and a series of slipways for hauling up destroyers, together with a slip for small craft, a wharf for ordnance purposes, and an auxiliary boat camber. The reclaimed area of the dockyard is faced seawards by a wharf wall constructed of interlocked concrete blocks, upon a new system, built in the sea without the aid of a dam, and having an unbroken line for wharfage purposes of about 1600 feet lineal, with a depth of water alongside of 33 feet at low water. Upon this wharf are erected powerful shears and cranes for the use of vessels alongside.

The older appellation of "harbour of refuge" has, from the point of view of the naval strategist, acquired a new and extended meaning, and while the modern defensive harbour may still serve as shelter from bad weather, it further fulfils the not less important function of protection from torpedo attack. The defensive harbour now in course of construction at Gibraltar is formed by the enclosure of a water area of about 440 acres, of which some 250 acres will have a minimum depth of 30 feet at low water. This enclosure is formed by three several works of considerable magnitude: the *New Mole Extension* forming the southerly boundary, the *Commercial Mole* on the north side, and the *Detached Mole* forming the westerly boundary, while two entrances, each 200 yards wide, form the approaches to the harbour from the sea. The *New Mole*, so called in distinction from the Old Mole or Devil's Tongue at the northern end of the town, is supposed to have been commenced during the Spanish occupation in the year 1620. Both New and Old Moles are frequently referred to in Drinkwater's *History of the Siege of Gibraltar*, and the successful assault upon the former by the officers and men of the British fleet forms a leading incident in the capture of Gibraltar by Admiral Sir George Rooke in 1704. Additions to the length of this mole were made at various times, and in 1895 the total length of the artificial mound was about 1400 feet. The extension now in progress will add 2700 feet to this length.

This mole is formed of a rubble mound, with a top width of 102 feet, the stone being obtained from adjacent quarries and deposited in the sea by barges. The harbour side is faced by a continuous wharf wall, having 30 to 35 feet depth of water alongside, and the total length of wharfage available for ships of war for coaling or other purposes will be 3500 feet. The *Detached Mole*, forming the westerly boundary of the harbour, is of a different type of construction. It is a vertical wall formed of massive concrete blocks, the greater number of which are of 32 tons in weight, arranged upon what is known as the sloping block system, and founded upon a rubble mound of stone deposited from barges and levelled for the reception of the blocks by divers. As this breakwater stands isolated, some half a mile from the nearest point on shore, in from 45 to 65 feet depth of water, and has at no time during its construction been connected with the land by any temporary staging, a brief description of the method employed for commencing its constuction will not be without interest. A box-shaped steel caisson, 33 feet wide, 74 feet in length on the top, 101 feet in length at the bottom, and 48½ feet high, fitted with compartments and with ends sloped to the angle of the blockwork, was constructed in this country, shipped to Gibraltar, re-erected, launched, towed to its correct position, and sunk, by the admission of water, on the rubble mound before mentioned. Concrete was then filled in as rapidly as possible until the entire mass, weighing about 9000 tons, had formed, so to speak, an artificial rock or island in the sea, being, in fact, a completed section of the breakwater itself. Upon this foundation were erected two block-setting Titans (see TITAN CRANES), capable of setting 36-ton blocks at a radius of 75 feet, by which means this mole has been rapidly extended north and south to its full length of 2720 feet. The blocks, having been transported from the block-yard by rail and then shipped in barges to the site of the mole, are laid in their sloping position by means of special apparatus designed and patented by the writer.

The *Commercial Mole*, forming the northerly boundary of the harbour, is intended to serve the commercial requirements of the colony, while at the same time it forms an integral portion of the defensive scheme. This mole starts from the neighbourhood of the Waterport wharf, alongside the Old Mole or "Devil's Tongue," an appellation given to this portion of the defences of the fortress during the siege of Gibraltar in 1779–83, on account of the annoyance to the besiegers caused by its flanking fire. The mole consists of a rubble mound projecting in a westerly direction, furnished with five jetties, lying north and south, and terminating in a western arm lying parallel to the jetties. Each jetty and the western arm is faced with a concrete wharf wall, and the total length of wharfage available for mercantile coaling or other purposes amounts to 7000 feet lineal, with a depth of water alongside ranging from 20 to 30 feet. Extensive coal and bonded stores are provided, and an open viaduct is constructed in the connecting arm, leaving a waterway for the purpose of giving circulation to the enclosed waters of the harbour, which is being dredged to secure the depths already referred to.

*Devonport and Keyham.*—Prior to the period dealt with in this article, the works at Keyham described in the ninth edition article on DOCKYARDS had been completed; railway communication with the Cornwall line was established, and a tunnel formed a connexion between the two yards. Keyham yard in 1880 consisted substantially of two basins, the north basin of 9 acres and the south basin of 7 acres in extent; three docks, having floor-lengths of

295, 347, and 413 feet respectively, and extensive dockyard buildings. The most important addition to Devonport yard at this period was the construction of Dock No. 3, having a floor-length of 415 feet, with 34′ 9″ over the sill at high-water springs, and this, with certain dockyard buildings, constitute the principal features in the development of Devonport yard up to the year 1901. Seamen's barracks of considerable architectural importance, with accommodation for 1000 men, together with officers' quarters, drill shed, commandant's residence, &c., were completed on a site to the north of Keyham yard and overlooking the Hamoaze. Such in brief was the extent to which H.M. dockyards at Devonport and Keyham had been developed up to the time when the scheme sanctioned by Parliament under the Naval Works Loan Act of 1895 was first commenced, and the mud flats to the northward of Keyham yard, and immediately in front of the seamen's barracks above referred to, became the active scene of the new works.

These works present three leading features: a tidal basin with entrance from the Hamoaze; a group of three graving docks and entrance lock; and a large enclosed basin, with a coaling depot at the northern end. The tidal basin is in the immediate neighbourhood of the old Keyham north basin, and is 740 feet in length by 590 feet in mean width, with an area of 10 acres and a depth of 32 feet at low water of spring tides. This basin affords access to two graving docks of large dimensions, each dock serving also (when not occupied) as a lock for entrance into the closed basin. One of these docks has a length of 745 feet on floor, with $20\frac{1}{2}$ feet over the sill at low-water springs. The other is 741 feet on floor, with 32 feet over the sill at low-water springs. Each of these docks can be subdivided by means of an intermediate caisson. A third dock, opening out of the closed basin, is 480 feet in length, with $32\frac{1}{2}$ feet over the sill at high water of neap tides, and provision is made for an increase of length when required. An entrance lock, 730 feet in length between caissons, with 32 feet over the sill at low water of spring tides, gives direct access from the Hamoaze to the closed basin, which is 1550 feet in length, 1000 feet in width, and covers an area of $35\frac{1}{2}$ acres, with a depth of $32\frac{1}{2}$ feet at low-water springs. An additional entrance, closed by caissons, but without a lock, communicates with the Hamoaze. A wharf wall forming the eastern boundary of the closed basin will afford a length of wharfage of 800 yards, with 30 feet alongside at low-water springs. The site of these works is an expanse of mud overlying rock at varying depths, which in some places reach 100 feet or more below the level of coping. As the walls of docks, lock, and basins are in every case carried down to the rock, it follows that the process of constructing foundations at such great depths involves engineering operations of considerable magnitude and difficulty.

The docks and basins above described are remarkable for the depths at which their floors and entrances are laid, and this, combined with the tidal rise of $15\frac{1}{2}$ feet, causes the problem of closing and opening the dock and lock entrances to be attended with somewhat more than ordinary difficulty. It is therefore not out of place to describe very briefly the practice in this respect customary in H.M. dockyards. The ordinary lock gate usually found in private docks (though some of the finest modern docks use caissons) is too familiar to need description, but this form of closing an entrance does not afford facilities for carrying a railway line across the dock or lock, and where this is required a swing bridge must be constructed. In the case of H.M. dockyards it frequently happens that railway lines cross the dock entrances, and the weight to be transported by their means, such as heavy guns, boilers, machinery, and the like, would require a swing bridge of great strength and considerable span. It has consequently been found convenient and economical to construct the apparatus for keeping the water out of the dry dock in such a form as to combine the functions of a movable dam and a swing bridge, and this is done by the employment of so-called "caissons." The great majority of dock entrances in H.M. dockyards are closed by caissons, and these are, broadly, of two principal types — the floating or ship caisson and the sliding caisson. The former is sunk into its place in a groove prepared in the dock walls for its reception by means of water supplied by hose into a ballast tank, and raised again by letting the water out. The latter type consists of a rectangular steel or iron box-shaped dam, which is drawn across the entrance by machinery, or withdrawn into a recess provided in the side of the dock entrance when access is required into the dock. Both types can be designed to carry a railway across their upper deck capable of sustaining the heaviest loads ever required. When the caisson is in its place across the entrance and the dock is dry, it has of course to sustain the maximum water pressure which can come upon it at the highest tides. Owing to the causes above mentioned, the caissons at Keyham are of exceptional dimensions, and the mechanical problems to be dealt with in their design are of no ordinary kind. They are, as a rule, sliding caissons, constructed of riveted mild steel, and capable of withstanding a hydraulic pressure amounting in some cases to 3700 tons.

*Simons Bay* (*Cape of Good Hope*).—The existing naval yard at this station covers an area of about 13 acres, exclusive of the victualling establishment and naval hospital, and is provided with a small camber, slipways for torpedo-boats and small vessels, together with various dockyard buildings, storehouses, coal stores, &c., but has no dry dock or deep-water wharf. The new works proposed under the Naval Works Loan Act of 1899, at an estimated cost of two and a half millions sterling, are situated near Blockhouse Point, to the east of the present naval yard. These works consist of a tidal basin of 28 acres in extent, and with a depth of 30 feet at low-water spring tides, enclosed by a breakwater on the eastern and northern sides and a similar projecting arm or pier on the west. The entrance to the basin faces north-westerly, and is 300 feet in width. South of the basin is a large reclaimed area forming the site of the new dockyard. Opening from the basin is a dry dock, 750 feet in length on blocks, with an entrance 95 feet wide and having 30 feet over the sill at low-water spring tides.

This dock can be subdivided by an intermediate caisson in such a manner as to form two docks, respectively 400 feet and 320 feet in length, or 470 feet and 250 feet in length on blocks, as may be required, or the full length of 750 feet can be made available when necessary. The dockyard buildings include extensive shops for the chief engineer's and chief constructor's departments, the pumping-engine house, working sheds, &c., while ample space is reserved for additional docks and buildings. Berthing accommodation is provided in the basin alongside the wharf walls which surround it. The walls available for this purpose have a total length of 2585 feet lineal, are constructed of interlocked concrete block work, with an available depth of water of 30 feet at low water, and are furnished with powerful shear-legs and cranes for the use of vessels alongside. Extensive sheds for the storage of coal are provided. The whole of the dockyard area, together with that of the enclosing breakwater and pier, will be formed by reclamation from the sea; and as the total space thus created amounts to 35 acres, the entire extent of the proposed works, including the tidal basin, will amount to 63 acres in area. The works thus briefly described will, in combination with the existing yard, form an important naval station for the requirements of the fleet in South African waters.

*Hong-Kong*.—The naval yard at this important station consisted of an area of some $4\frac{3}{4}$ acres in extent, but unprovided either with basins, dry docks, or any wharfage suitable for large vessels. The widening range of political affairs in the East, and the increasing requirements of the navy in Chinese waters, had, however, made it obvious that the existing resources of the naval yard were inadequate. The result was an Admiralty scheme of enlargement. The principal features of this scheme are as follows: A tidal basin of $9\frac{1}{4}$ acres in extent is provided, having a depth of 30 feet at low-water springs, and enclosed by wharf walls, giving a total length of wharfage of 2900 feet lineal. A dry dock, opening direct into the roadstead, 550 feet in length on blocks, 95 feet wide at entrance, and with 30 feet over the sill at low-water springs, will accommodate the largest vessel in H.M. navy. Extensive workshops for the chief constructor's and chief engineer's departments, shears, cranes, pumping-engine house, and slipway for

small craft, will also be provided. The site of the extension will be formed by reclamation, and the additional area thus formed, including the basin, will equal $34\frac{1}{2}$ acres. The present yard will thus be increased from $4\frac{3}{4}$ acres to $39\frac{1}{4}$ acres in area, and the extension will mark an important stage in the development of the accommodation required to meet the necessities of the fleet in the East. The existing establishment at Kowloon will be augmented by the construction of coaling jetties, &c.

(*c*) *Naval Barracks, Hospitals, &c.*

The works in progress under this heading are included in the following general remarks on the shore establishments of the navy, which include barracks for the seamen, royal marines, and royal marine artillery, training schools, hospitals, and victualling stores. The policy in recent years with regard to naval barracks has been to provide buildings on shore in place of berthing the men in hulks moored alongside the dockyards; and in pursuance of this policy naval barracks have been provided, or are under construction, in the vicinity of the three great dockyards—Portsmouth, Devonport, and Chatham. At Portsmouth new barracks on the site of the old Anglesey barracks have been commenced, and when completed will provide quarters for 4609 officers and men. At Devonport, as before described, the naval barracks adjacent to the extension works at Keyham were erected to accommodate 1000 officers and men, and the buildings are now being extended so that the numbers may be increased to 2313 officers and men. At Chatham the site of the old convict prison is being utilized for constructing quarters for 3731 officers and men. The royal marines have barracks at Forton, near Gosport; at Stonehouse, near Plymouth; and at Chatham, with a depot at Walmer recently enlarged. The barracks and training establishment of the royal marine artillery are at Eastney, near Portsmouth, and provide accommodation for 1800 officers and men. The above-mentioned buildings include all necessary accessories, such as canteens, drill sheds, sick quarters, and the various buildings required for the accommodation and training of seamen and marines. The training schools on shore include the gunnery establishment at Whale Island in Portsmouth harbour, where an area of 73 acres has been formed by the deposit of excavated material from the dockyard extension works, and a gunnery school, provided for 1100 officers and men, with parade ground, gun drill battery, sick quarters, rifle range, &c. The establishment is about to be enlarged to accommodate an additional number of officers and men under instruction. At Dartmouth H.M.S. *Britannia* has hitherto been used as the training school for naval cadets, but a new naval college is now being erected on the high ground overlooking the site where the *Britannia* is moored. Greenwich Hospital, formerly appropriated to naval pensioners, is now used as a college for the instruction of naval officers in the more advanced branches of their profession, while at Keyham there is a college for engineer students. The largest naval hospital and medical school is at Haslar, near Gosport, covering an area of 88 acres, with beds for 1084 patients. Stonehouse Naval Hospital has 700 beds for the use of seamen and marines of the Devonport district. At Chatham the existing hospital accommodates nearly 250 patients, and a new hospital for 600 beds is under construction. Hospitals or sick quarters are also provided at Great Yarmouth, Dartmouth, Haulbowline, Portland, and South Queensferry. The chief victualling establishments are Deptford for the Thames, Chatham, and Sheerness; the Clarence Yard at Portsmouth; and the Royal William Victualling Yard at Plymouth and Haulbowline. Magazines for warlike stores are established close to the principal dockyards and within easy access by rail or water. At foreign stations Malta has a hospital and victualling yard, Gibraltar has a hospital, and the other chief naval stations in different parts of the world have a shore establishment on a scale adapted to meet their probable requirements.

**Under ordinary navy votes.**

The chief features in the extensions of H.M. dockyards carried out between 1880 and 1901 under the ordinary navy votes, and not already referred to, may now be briefly described.

*Portsmouth.*—The extension works at this dockyard, described in the ninth edition article DOCKYARDS, and completed prior to 1880, formed an important stage in the history of this station, and, together with the works at Chatham carried on at about the same period, marked an epoch of advancement in H.M. yards, following as they did the transformation which had already taken place in naval construction in the substitution of iron for timber and of steam in lieu of sail propulsion. This extension, commenced in 1867, was designed to meet the naval requirements of the day, and no works of equal magnitude have since been carried out at this port. The developments of naval architecture and the increasing length of modern cruisers necessitated, however, additional dry dock accommodation, and in 1896 Docks Nos. 14 and 15 were completed, having a floor length of 557 feet, with 33 ft. 10 in. over the sill at high-water springs. These were the longest docks in the service, with the exception of a double dock at Portsmouth. Other important works carried out since the completion of the extension may be summarized as follows:—The renewal and extension of the jetties on the west front, and, in late years, the construction of jetties at the entrance to the tidal basin and at the north wall; a torpedo range in the harbour; the establishment of a coaling wharf at coaling-point, with hydraulic appliances; the widening of the entrance between Basins 4 and 5; the erection of various buildings, such as torpedo and gun-mounting stores, electrical shops, and the like, with numerous subsidiary works of more or less importance. Extensive dredging of the harbour is in progress for the purpose of increasing the berthing accommodation for the fleet.

*Chatham* dockyard covers an area of 516 acres, including the extension works described in the ninth edition article on DOCKYARDS and completed prior to 1880. No works of equal magnitude or importance have been carried out since that date at this yard, but among the principal additions or improvements which have been made from time to time may be mentioned extensive dredging operations in the Medway for the deepening of the navigable channel and approach to the basins and docks, the provision of a 160-ton crane, the lengthening of Dock No. 5, and the erection of various yard buildings. Additional dry dock accommodation is provided for under the Naval Works Act.

*Pembroke* dockyard has an area of some 79 acres, and is furnished with one dry dock 387 ft. 8 in. in length on blocks, numerous building slips of various lengths, and the usual shops, stores, and other dockyard buildings. The Carr Rocks jetty now under construction will form, when completed, a valuable addition to the resources of the yard in the fitting out and completion of vessels.

*Haulbowline* dockyard was practically completed about the year 1889, and covers an area of 33 acres, while the adjoining victualling yard of 22 acres makes the total area of this naval station 55 acres. The yard includes a closed basin of 9 acres in extent, with entrance from Queenstown harbour, and with 32 ft. 8 in. over the sill at high-water springs. A dry dock at the south end of the basin has a length of 408 feet on blocks, and is

94 feet wide at entrance. The basin is enclosed by wharf walls with a total length of 1700 feet, and furnished with 60-ton shears, cranes, &c. A slipway is provided at the south end of the basin, and the dockyard buildings comprise a pumping-engine house, constructors' shops, furnace house, worksheds, &c.

*Malta* dockyard was but briefly referred to in the ninth edition article, and some further notice is desirable here. The dock and victualling yards occupy together an area of some 100 acres, spread over the shores on both sides of those arms of the grand harbour known as "Dockyard" and "French" creeks, the dockyard being located partly on the former, but principally on the latter creek. In 1880 the graving dock accommodation consisted of one double dock at the extremity of Dockyard creek, known as No. 1 and 2 Docks, with a total length of about 525 feet, and with 25 feet over the sill at average water level, the tidal range at Malta being but slight; and opening into French creek a dry dock of more modern construction, known as No. 3, or the Somerset Dock, 427 feet long on floor, and with 34 feet over the sill. Subsequently to this period the fine range of buildings known as the iron ship repairing shop was erected close to the Somerset Dock, and added greatly to the repairing resources of the yard. Dock No. 4, or the Hamilton Dock, was completed in 1891, having a length on floor of 520 feet, a width of entrance of 94 feet, and with 35 ft. 5 in. depth over the sill at average water level. Associated with this dock was the construction of adjacent deep-water wharf walls, together with the great 160-ton crane. New gun-mounting stores, boiler shop, boat sheds, canteen, coal stores, &c., are among the more recent additions to the yard, and preparations are being made for additional dry dock accommodation

*Halifax* naval yard has an area (including the hospital ground) of about 18 acres. The yard is provided with slipways for small craft, shops, stores, &c., but does not possess a dry dock. A private dock in the immediate vicinity completed in 1889, under a Government subsidy, has a floor length of 560 feet, a width of entrance of 89½ feet, with 30 feet over the sill at high-water springs.

*Bermuda* naval yard is provided with a camber or small enclosed harbour protected with a breakwater. Within the camber is moored an iron floating dock having an inside length of 330 feet. Additional dock accommodation is contemplated.

*Jamaica* naval yard covers an area of about 13 acres, but there is no graving dock.

*Sydney*.—The naval yard at this port is situated on Garden Island, Wooloomooloo Bay, and is provided with a deep-water wharf with shears, an engineer's shop, naval and victualling stores, coal stores and coaling wharf, boat slip, &c. Accommodation for docking H.M. ships is found in the Fitzroy and Sutherland Docks at Cockatoo Island, the former having a length of 474 feet on blocks, with an entrance of 59 feet in width; and the latter a length of 602 feet on blocks, with an 84-feet entrance, having 32 feet over the sill at high-water spring tides.

In addition to the above are naval stations at Ascension, Bombay, Calcutta, Trincomalee, and Esquimalt, together with works in contemplation at Wei-Hai-Wei.

The literature on the subject of H.M. dockyards is not extensive, but the following papers and works may be consulted with advantage:—BERNAYS. "Chatham Dockyard Extension Works," *R. E. Lectures*. Chatham, 1879.—COLSON and MEYER. "Portsmouth Dockyard Extension Works," *Proc. Inst. C. E.*, 1881.—COLSON. "Hamilton Graving Dock, Malta," *Proc. Inst. C. E.*, 1894.—"The Two New Docks at Portsmouth," *Engineer*, vol. lxxxi.—COODE, SON, and MATTHEWS. "Dover Harbour Works," *Brit. Assoc. Mechanical Science Section*. London, 1899.—See also VERNON-HARCOURT. *Harbours and Docks*. London, 1885.—C. COLSON. *Notes on Docks and Dock Construction.* London, 1894. (H. F.)

*Dockyard Administration*.—To a great maritime power like Great Britain the importance of possessing adequate dockyards fitted with every requirement for a fleet is sufficiently obvious. In the dockyard are brought together all the materials of every class and kind required in the construction of ships; and here is provided the labour required for the building of them. In the dockyard the ships receive their provision for offence and defence and their means for navigation, and are fitted in every detail for their service. Depending as the British empire does on the efficiency of its navy to safeguard it from attack and to protect its commerce, it is essential to remember that the navy could not carry on its work successfully if there did not exist an efficient civil service such as is found in British dockyards. In speaking of these establishments, it may be necessary to note that, in addition to the work in the yards of the State, much of that which has been alluded to is carried on in private yards, though the ships built in these last are equipped and brought to completion in the Government establishments. A dockyard may be defined as an enclosure in which are sufficient basins, building slips, dry and wet docks, ammunition, store and coal magazines, coaling wharfs and appliances, and all other things necessary for the life of the ships. It may be noted that a wet dock is a receptacle for a ship which is open to the tide, and a dry dock one specially constructed to receive ships for the repair of the under-water portions of their hulls in the most advantageous conditions.

An ordinary observer, looking at the great mass and variety of stores arriving alongside a ship, and seeing hundreds of men busily engaged in every part of her, may not at once recognize the existence of a system. But closer observation will show that there is a thorough organization, that every man knows his duties, and that every separate party bringing stores or requirements is informed as to exactly what is required to be done with them. The operations go on with celerity, regularity, and order, and it is a matter of astonishment to those who know the vast and varied character of the work how quietly it proceeds and how soon order is evolved from apparent chaos. The dockyards at home and abroad lie within the province of the controller of the navy (the third lord of the Board of Admiralty); and the director of dockyards, whose office, replacing that of surveyor of dockyards, was created in December 1885, is responsible to the controller for the building of ships, boats, &c., in dockyards, and for the maintenance and repair of ships and boats, and of all steam machinery in ships, boats, dockyards, and factories. The director of naval construction, who is also deputy-controller, is responsible, not only for the design of ships, but for their construction, in the sense that he approves great numbers of working drawings of structural parts prepared at the dockyards. But the director of dockyards is the Admiralty official under whose instructions the work goes on, involving the employment and supervision of an army of artisans and labourers. Instructions, therefore, emanate from the Admiralty, but the details lie with the dockyard officials, and in practice there is a considerable decentralization of duties.

The superintendent of a British dockyard is a rear-admiral in the case of Portsmouth, Devonport, and Chatham, and abroad of Malta, but a captain is the superintendent of smaller yards, Sheerness and Pembroke at home, and Gibraltar, Bermuda, Jamaica, Hong-Kong, Sydney, and Ascension abroad; and there are smaller establishments at Halifax, N.S., the Cape of Good Hope,

Trincomalee, and Vancouver; while the Indian Government has dockyards at Bombay and Calcutta.

The chief function of a dockyard is the building and maintaining of ships in efficiency. The constructive work is carried out under the care of the chief constructor of the yard, in accordance with plans sent down from the Admiralty. The calculations for displacement, involving the draught of water forward and aft, have already been made, and, in order to ensure accuracy in the carrying out of the design, an admirable system has been devised for weighing everything that is built into the new ships or that goes on board; and it is astonishing how very closely the actual displacement approximates to that which was intended, particularly when the tendency of weights to increase, in perfecting a ship for commission, is considered. The late Mr Froude, who carried out experiments for many years at Gosport as to the best form for the hulls of ships, was amazed at the great magnitude of the calculations involved in the design of modern vessels. The ship being built to her launching weight, the duty of putting her into the water devolves upon the chief constructor of the yard, and failures in this matter are so extremely rare that it may almost be said they do not occur. As soon as the ship is water-borne the responsibility falls upon the King's harbour master, who has charge of her afloat and of moving ships into the fitting basins. When the ship has been brought alongside the wharf, the responsibility of the chief constructor of the yard is resumed, and the ship is carried forward to completion by the affixing of armour plating, the mounting of guns, often the instalment of engines, boilers, and electrical and hydraulic gear, and the fitting of cabins for officers, mess places for men, and storerooms, and a vast volume of other work unnecessary to be specified. In regard to the complicated details of guns and torpedoes, the captains of the gunnery and torpedo schools have a function of supervision. The captain of the fleet reserve also closely watches the work, because, when the heads of all departments have reported the ship to be ready, she has to be inspected by the commander-in-chief at the port, and then passed into the fleet reserve as ready for sea, and there the captain of the fleet reserve is responsible for her efficiency. Other important officers of a dockyard are the chief engineer; the superintendent civil engineer, who has charge of the work involved in keeping all buildings, docks, basins, caissons, roads, &c., in repair; the naval store officer, who has charge of most of the stores in the dockyard; and the cashier of the yard, whose name sufficiently expresses his duties.

The system of conducting business at the dockyards is analogous to that which prevails at the Admiralty. There is personal communication between the officers responsible for the work, and, as at Whitehall, facilities are afforded for coming to rapid decisions upon matters that are in hand, and the operations are conducted with an ease which contributes much to efficiency. It is the custom for all the principal officers of the dockyard to meet at the superintendent's office at 9.30 A.M. every day, in order that they may be made acquainted with the orders from the Admiralty and may discuss the work of the day, settling the necessary details as they affect the several departments. It thus follows that there is a complete understanding among the principal officers as to the work to be done, and a full recognition of the part which each is to play in its execution. The result is that time is gained by the avoidance of the necessity of passing minutes from department to department—a system which would act prejudicially in many cases.

An efficient police service is a necessity in a dockyard. The force necessary is supplied from the Metropolitan police, and is under the orders of the superintendent of the yard for duties connected with it, and under the commissioner of police for the discipline and disposition of the force. The charges are, of course, paid by the Admiralty, and the system answers well.

(R. V. H.; J. LD.)

### 2. United States.

The shore stations under control of the Navy Department (see Admiralty Administration), and collectively known as naval stations, are under different names according to their nature. Of those called *Navy Yards*, and intended for the general purpose of sources of supply and for repairs of ships, there are within the United States twelve in number. Two of them are on the Pacific coast, situated on Puget Sound, at Bremerton, Washington; and at Mare Island, near San Francisco. The other ten are on the Atlantic coast, and are situated at Kittery, Maine; Boston, Mass.; New London, Conn.; Brooklyn, N.Y.; Philadelphia, Pa.; Washington, D.C.; Portsmouth, Va.; Port Royal, S.C.; Pensacola, Fla.; and Key West, Fla. There are also such naval stations at Havana, Cuba; San Juan, Porto Rico; Honolulu, H.I.; Cavite, P.I.; and Island of Guam, in the Ladrones Islands. A floating dock with a lifting capacity of 15,000 tons is being built for Government use at Algiers, La., near New Orleans.

Besides these, there are important naval stations established for special purposes, but which in some cases are also available for ports of supply and for repairs. These are: the Naval Academy, Annapolis, Md., for the instruction of naval cadets; the training stations at Newport, R.I., and Yerba Buena Island, Cal., for the instruction of apprentices; the proving ground at Indian Head, Md., on the Potomac river, where all Government-built ordnance is tested; the War College at Newport, R.I., for the instruction of officers; the torpedo station at Newport, for the instruction of officers and men in torpedoes, electricity, and submarine diving; the naval observatory at Washington; and the marine post at Sitka, Alaska. Coaling depots have been established at Honolulu, Pago Pago, Samoan Islands, and at Manila, P.I. Numerous others are to be established soon, both at home and abroad.

Naval hospitals are located at the Portsmouth, Boston, New York, Philadelphia, Washington, Norfolk, and Mare Island yards; at Newport, R.I.; Cavite, P.I.; and Yokohama, Japan.

Information regarding the dry docks is given in the table on the following page.

The commandant of a navy yard and station, who is usually a rear-admiral, is its commander-in-chief. His official assistants are called heads of departments. The captain of the yard, who is next in succession to command, has general charge of the water front and the ships moored there, and of the police of the navy yard; it is his duty to keep the commandant informed as to the nature and efficiency of all work in progress. The equipment officer has charge of anchors, chains, rigging, sails, and the electric generating plant. The other heads of departments are the ordnance officer, the naval constructor, the engineering officer, the general storekeeper, the paymaster of the yard, the surgeon, and the civil engineer. The clerks and draughtsmen employed by these officers are appointed under civil service rules, and their employment is continuous so long as funds are available. The foremen are selected by competitive examination, and their number is fixed. In the employment of mechanics and labourers, veterans are given preference, after which follow persons previously employed who have displayed especial efficiency and good conduct. The rates of wages

are determined semi-annually by a board of officers, who ascertain the wages paid by private establishments in the vicinity of the navy yard. Eight hours constitute the legal work day. When emergencies necessitate longer hours the workmen are paid at the ordinary rate plus 50 per cent.

The nature and extent of work to be performed upon naval vessels is determined by the Secretary of the Navy; the commandant then issues the necessary orders. The material required is obtained by a system of requisitions, which provide for the purchase from the lowest bidder after open competition. Heads of departments initiate the purchase of materials which are peculiar to their own work; ordinary commercial articles, however, are usually carried in a special stock called the "Naval Supply Fund," which may be drawn upon by any head of department. All materials are inspected, both as to quantity and quality, by a board of inspectors consisting of three officers.

(W. T. S.)

### 3. Other Dockyards.

*France.*—The French coast is divided into five naval arrondissements, which have their headquarters at the five naval ports, of which Cherbourg, Brest, and Toulon are the most important, Lorient and Rochefort being of lesser degree. All are building and fitting-out yards. Each arrondissement is divided into sous-arrondissements, having their centres in the great commercial ports, but this arrangement is purely for the embodiment of the men of the Inscription Maritime, and has nothing to do with the dockyards as naval arsenals. In each arrondissement the vice-admiral, who is naval prefect, is the immediate representative of the Minister of Marine, and has full direction and command of the arsenal, which is his headquarters. He is thus commander-in-chief, as also governor-designate for time of war, but his authority does not extend to ships belonging to organized squadrons or divisions. The naval prefect is assisted by a rear-admiral as chief of the staff (except at Lorient and Rochefort, where the office is filled by a captain), and a certain number of officers, the special functions of the chief of the staff having relation principally to the efficiency and *personnel* of the fleet, while the "major-general," who is usually a rear-admiral, is concerned chiefly with the *matériel*. There are also directors of stores, of naval construction, of the medical service, and of the submarine defences (which are concerned with torpedoes, mines, and torpedo-boats), as well as of naval ordnance and works. The prefect directs the operations of the arsenal, and is responsible for its efficiency and for that of the ships which are there in reserve. In regard to the constitution and maintenance of the naval forces, the administration of the arsenals is divided into three principal departments, the first concerned with naval construction, the second with ordnance, including gun-mountings and small-arms, and the third with the so-called submarine defences, dealing with all torpedo *matériel*.

*Cherbourg*, at the head of the Cotentin Peninsula, is a dockyard and harbour chosen on geographical grounds and possessing no natural advantages. It owes its existence in the first place to Louis XIV., and Vauban as the engineer, but the construction of the great breakwater, which encloses the harbour on the north, was a work of very great difficulty; it, after being damaged and washed away several times, was recommenced in 1832 and completed. It is over 4000 yards long, is well protected by forts, and has two entrances, the eastern passage having been narrowed to 500 yards by a second breakwater carried out from the Batterie des Grêves to the Ile Pelée, while the western entrance is about 1000 yards wide, and lies between the main breakwater and a mole run out from the Fort de Querqueville. The arsenal covers an area of about 54 acres. It consists of an entrance port and of two large basins, all cut out of the solid rock, and there are eight dry docks, of which the principal are capable of admitting the largest vessels. The arsenal is very completely fitted, and there are extensive stores, magazines, barracks, and engineering shops. The small battleship *Henri IV.* has been built there, with several modern armoured cruisers, and Cherbourg has become the principal arsenal for the building of submarine boats.

The harbour and arsenal of *Brest* are approached through the Goulet, which is divided into two deep channels by the Fillettes and the Mengam Reef, beyond which a great expanse of water is reached, stretching eastward to Landevenec and having the arsenal of Brest on the north. The arsenal lies in a rocky valley open to the harbour, into which the little river Penfeld flows, the two sides of the channel being united by a splendid revolving bridge, which gives a headway at high tides of 72 feet. The water space has an average width of 110 yards in the port, with a maximum of about 170 yards and a minimum of 75 yards. Near the entrance is the great basin excavated in 1683 and enlarged in 1864. Beyond are the stores and magazines, the old prison, the rope-works, the saw-yard, and the building slips, while on the Recouvrance or western side, beyond the bridge, are the gun-shops, the *salle d'armes*, machine-shops, basins and slips, as well as coaling and other establishments. The arsenal possesses a dry dock for destroyers and gunboats, two for cruisers and small battleships, and two for the largest classes of ships. A reconstruction has been begun which will give two additional large docks, of which one can be used for two vessels owing to the provision of a dividing dock-gate. Another dock of large size is to be constructed in the commercial port. At the entrance to the arsenal, and actually in the harbour of Brest, a jetty has been constructed, forming what is called the *rade-abri*. The works there are to be extended, and magazines and engineering shops are to be built on land won from the harbour. In regard to building facilities, it may be said that Brest has five slips for the construction of vessels ranging from 150 tons to 13,000 tons. The sinuosities of the valley in which the arsenal lies render it somewhat incommodious, but the protective harbour mentioned above will considerably increase the facilities. The arsenal and the harbour, as well as its approaches, are protected by a great number of forts and batteries furnished with modern heavy and quick-firing guns.

The harbour of *Lorient* is formed by the junction of the Blavet and Scorff, and is 3½ miles long, the naval arsenal being on the Scorff, and chiefly on its right bank. Lorient is a port of construction, but large ships built there are usually fitted at Brest. The largest battleships, such as the *Bouvet*, *Brennus*, and *St Louis*, as well as first-class armoured cruisers, have been constructed at the port. There are two dry docks, and the port is well equipped, but the harbour is shallow, and will not accommodate a large squadron, the usual anchorage being to the north of the Ile Groix.

*Rochefort*, the head of the fourth arrondissement, dates from the time of Louis XIV., and is formed by the river Charente, the waters of which are being deepened to facilitate the approach for larger vessels. The largest ships built at the port do not exceed 8000 tons. There are two dry docks, three building slips, and a torpedo basin.

*Toulon* is the most important of the French dockyards, and is the headquarters of the Mediterranean fleet. The arsenal, which was created by Louis XIV., Vauban being the engineer of the works, lies on the north side of the Petite Rade. This is approached from the Grande Rade by passages at the north and south ends of a long breakwater which extends from the direction of Le Mourillon towards the Cépet Peninsula. The arsenal has been greatly enlarged, and at the present time the water space within the moles amounts to about 150 acres, while the quays approach 4 miles in length. Outside in the Petite Rade is a splendid protected anchorage for a great fleet, the whole being commanded by many forts and batteries. There are four great basins approached from the Petite Rade—the Vieille Darse, to the east, on the side of Le Mourillon; the Darse Vauban, next to it; and the Darse de Castigneau and the Darse Missiessy, farther to the west. In the Darse Vauban are three dry docks, two of them 246 feet long, with a depth of water on the sill of about 20 feet; while the third is 283 feet long, with a depth of over 24 feet. Three other dry docks are in the Darse de Castigneau, of which one is in two sections. The largest of the docks is 385 feet long, and the depth of water on the sill in all these docks averages 30 feet. In the Darse Missiessy are two dry docks, 426 feet long, with a depth on the sill of over 32 feet. There are several building slips, and the yard is supplied with a gun foundry and wharf, fitting shops, boiler works, victualling and other establishments, rolling mills, magazines, and everything that can be required to make it the efficient base of a great fleet. Le Mourillon is a subsidiary yard at Toulon, devoted chiefly to ship-building, and possessing large facilities, including five covered slips.

*Corsica*, which has naval harbours at Ajaccio and other places, is a dependency of the arsenal at Toulon. Porto Vecchio is intended to be made a centre of the mobile defence of the island, with every facility for the repairing of torpedo-boats; Bonifacio to be

improved as a secondary station; Bastia to be provided with a floating dock; and minor establishments to be formed at Calvi and the Ile Rousse.

Docking facilities are being increased in *Algeria*, and the naval station is being united with that of Tunis. *Bizerta*, the Tunisian port, has been made a naval base by the deepening and fortifying of the canal which is the approach to the inner lake, upon which naval establishments are being constructed for the refitting, coaling, and provisioning of the fleet. There are arsenals also at Saigon and Hai-phong, and an establishment at Diego Suarez, which is being extended.

The subsidiary establishments in France are the gun foundry at *Ruelle;* the steel and iron works at *Guérigny*, where anchors, chains, and armour-plate are made; and the works at *Indret*, on an island in the lower Loire, where machinery is constructed. There are many private shipbuilding establishments in the country, the most important being the Forges et Chantiers de la Méditerranée at *La Seyne*, on the lesser roadstead at Toulon, where very many French and foreign warships of the largest classes have been built. The same company has a building yard at *Graville*, near Havre. Other establishments are the Ateliers et Chantiers de la Loire, at *Saint Nazaire;* the Normand Yard, at *Havre;* and the Chantiers de la Gironde, near *Bordeaux*.

*Germany*.—With the expansion of the German navy considerable additions have been made to the two principal dockyards. These are Wilhelmshaven, the naval headquarters on the North Sea, and Kiel, the headquarters on the Baltic, Danzig being an establishment of lesser importance, and Kiao-chow an undeveloped base in the Shan-tung peninsula, China. The chief official at each home dockyard is the superintendent (Oberwerftdirektor), who is a rear-admiral or senior captain directly responsible to the Naval Secretary of State. Under the superintendent's orders are the chief of the "Ausrüstung" department, or captain of the fleet reserve, the directors of ordnance, torpedoes, navigation, naval construction, engineering, and harbour works, with some other officers. The chiefs of the constructive and engineering departments are responsible for the building of ships and machinery, and for the maintenance of the hulls and machinery of existing vessels; while the works department has charge of all work on the quays, docks, &c., in the dockyard and port. A great advance has been made in increasing the efficiency and capabilities of the imperial dockyards by introducing a system of continuous work in the building of new ships and effecting alterations in others, and German material is exclusively used.

*Wilhelmshaven*, on the Jade, is an artificial port, and has been constructed entirely since the year 1857, when extensive works were undertaken to protect the port from the inroads of the North Sea. The old port is on the western side, where, communicating with the sea by the fitting basin, is a building harbour with three dry docks and two building slips. Here two other large dry docks are now being constructed at a total cost of 12 million marks, partly contributed by the North German Lloyd in consideration of the navy forgoing the right to precedence over all vessels of the mercantile marine in regard to the use of the company's dock at Bremerhaven. This renunciation only applies to times of peace. The new docks will admit the largest men-of-war, even if lying deep in the water through the flooding of compartments, and will be provided with very powerful pumping apparatus, which will empty them in 2½ hours. After the war with France a second building period was entered upon at Wilhelmshaven, and works, including another harbour entrance, were continued until 1886. A new mole is now being built on the east side, where a third entrance to the harbour is projected, as well as the construction of a great basin and other works. There are at the present time two large building slips at the yard, a floating dock, and the five dry docks, built and building, alluded to above. The machine-shops, ordnance, and other stores and magazines are very extensive.

The North Sea station is now in direct communication with the arsenal at *Kiel*, on the Baltic, by way of the Kaiser Wilhelm Canal from Brunsbüttel, on the Elbe, to Holtenau, on Kiel Bay. Kiel is an extremely important naval station on the eastern side of the Schleswig-Holstein neck and on one of the finest harbours in the world, and possesses a fully equipped arsenal equal to all the requirements of the Baltic command. Kiel itself has greatly grown since the war of 1864 gave it to the Prussians. The arsenal is provided with a complete establishment for the building, fitting, and provisioning of a great fleet; and the docking facilities are being increased by the building of two great dry docks analogous to those at Wilhelmshaven. There are at the present time four building and patent slips, four dry docks, and two floating docks. A new harbour for torpedo craft is being constructed in Wick Bay, south of the mouth of the Kaiser Wilhelm Canal. No account of Kiel would be complete without a reference to the Germania Yard, which is now an establishment of the Krupp firm, and is capable of constructing vessels of the largest class. There are ten building slips in this yard, ready or projected, four having lately been built and roofed in, so that work can go on in all weathers. The Howaldt works at Kiel are also of great importance, and have large building facilities, which are being added to, with a floating dock for ships of 11,000 tons.

*Danzig* is a yard of lesser importance, but very completely equipped for the building of small armour-clads and cruisers. Here are two building slips and one dry dock. The Schichau Shipbuilding Works at Elbing (where torpedo craft are built) have also an important establishment at Danzig, and vessels of the largest class have been built there. The Vulkan Yard at Bredow, near Stettin, the Weser Company at Bremen, and the establishment of Blohm & Voss at Hamburg, are other important private establishments which have built many vessels for the German navy as well as for foreign states.

*Russia*.—In Russia the naval ports are of two classes. The most important are Cronstadt, St Petersburg, and Nicolaieff. Of lesser importance are Reval, Sveaborg, Sebastopol, Batum, Baku, and Vladivostok. The last-named port does not lose importance through the acquisition of Port Arthur, which, however, is rapidly becoming the chief Russian naval base in the Pacific. The administration of the larger ports, except St Petersburg, which is under special regulations, is in the hands of vice-admirals, who are commanders-in-chief, while the smaller ports are under the direction of rear-admirals. All are directly under the Minister of Marine, except that the Black Sea ports and Astrabad, on the Caspian, are subordinate to the commander-in-chief at Nicolaieff. Latterly Sebastopol has grown in importance, and will ultimately become a purely naval harbour, the commercial harbour being removed to Feodosia. The Russian Government proposes also to remodel the harbour works at St Petersburg and Cronstadt, and it is stated that the latter will become a naval port only. The Emperor Alexander III. Port at Libau, on the Baltic, in a region less liable to be icebound in the winter, is approaching completion. Considerable progress has been made in building ice-breaking vessels, by which it is hoped to maintain open passages to the ports during the winter months. A small port is being formed on the White Sea, which may ultimately be connected with the Gulf of Finland by a canal through the lake region.

There are two Government dockyards in the city of St Petersburg, both under the supervision of the port admiral. The most important of these is the new Admiralty Yard in the centre of the city, where both building and repairing work goes forward. There are three building slips in the yard, of which two, for the construction of the largest battleships, are new and of stone. The slips are housed in, so that the building work can go on in all weathers. At this yard there is also a very large experimental basin, some 400 feet in length, for trials with models of vessels. The yard is well provided with appliances, and there are two large machine-shops. The Galerny Island Yard is a little lower down the river, and is an important building establishment entirely devoted to construction. There are two building slips for large vessels, besides numerous workshops, storehouses, and other buildings, and a very fine moulding loft about 500 feet long and nearly 100 feet broad. The battleships *Alexander II.*, *Gangut*, *Poltava*, *Petropavlovsk*, *Sevastopol*, and *Orel* have been built at the Galerny Yard.

The Baltic Yard is near the mouth of the Neva, and was originally known as the Baltic Shipbuilding and Engineering Works, but it was taken over by the Ministry of Marine, which owned most of the shares, in 1894. Since that time the establishment has been enlarged, and a new stone building slip, 520 in length, completely housed in, has been finished, and numerous buildings have been erected. Here the *Rurik*, *Rossia*, *Gromoboi*, and other powerful cruisers were built. The Baltic works are now directed by a constructor of the imperial navy, but the work is not entirely confined to warship building.

The dockyard at *Cronstadt* is the principal arsenal for supplying

the Baltic fleet with stores and ammunition, and is largely used for repairs, there being four dry docks—the Alexandrovsky, 584 feet long and 85 feet wide; the Constantinovsky, 490 feet long and 73 feet wide; the Nikolaievsky; and the Petrovsky. There are numerous workshops, storehouses, magazines, and steam factories, with a depôt for torpedoes and a torpedo workshop. The workmen employed at St Petersburg number about 3500, at the Baltic Yard about 7250, and at Cronstadt about 3830. There are no strictly private yards for the building of large vessels in Russia, with the exception of the Black Sea Company at Nicolaieff. Messrs Creighton build torpedo-boats at Abo in Finland, and the Admiralty has steel works at Ijora, where some torpedo-boats have been built; and other ordnance and steel works are at Obukhoff and Putiloff. The new port at Libau includes an outer port, a naval port, and a commercial harbour. In the first named is a large basin for ships completing, surrounded by storehouses, workshops, and other buildings, as well as another large basin with dry docks and workshops for repair, the two being connected by a canal. The works in the naval port were approaching completion in 1901.

At *Vladivostok* a fine new dry dock has been opened, which is 550 feet long and 90 feet wide. The facilities of *Port Arthur* are being considerably developed, and the completion of the railway adds greatly to the importance of the port.

*Italy.*—The principal Italian state dockyards are Spezia, Naples, and Venice, the first named being by far the most important. It covers an area, including the water spaces, of 629 acres, and there are five dry docks, three of them being 433 feet long and 105 feet wide, and two of them 361 feet long and 98 feet 6 inches wide. The dockyard is very completely equipped with machinery of the best British, German, and Italian makes. At Spezia several of the finest Italian ships have been built. The number of hands employed in the yard averages 4000. Spezia has two building slips, and for smaller vessels there are two in the neighbouring establishment of San Bartolommeo (which is the headquarters for submarine mining), and one at San Vito, where is a Government gun factory.

The dockyard at *Naples* covers an area of about 18 acres, but at Castellammare the establishment is a little larger. There are four building slips at the last-named establishment, and a fine dry dock is at Naples.

At *Venice* are two fine dry docks, 361 feet long, and two building slips, and the yard is well equipped for turning out iron and steel forgings. A large dry dock has been built at Taranto. There is a small naval establishment at Maddalena Island on the Strait of Bonifacio. The Italian Government has no gun or torpedo factories, nearly all the ordnance coming from the Armstrong factory at Pozzuoli, near Naples, and the torpedoes from the Schwarzkopf factory at Venice, while armour-plates are produced at the important works at Terni. Machinery is supplied by the firms of Ansaldo, Odero, Orlando, Guppy & Hawthorn, and Pattison. The three establishments first named have important shipbuilding yards, and have constructed vessels for the Italian and foreign navies. The Orlando Yard at Leghorn is Government property, but is leased by the firm, and possesses five building slips.

*Austria-Hungary.*—The naval arsenal is on the well-protected harbour of Pola, in Istria, which is the headquarters of the national navy, and includes establishments of all kinds for the maintenance of the fleet. There are large building and docking facilities, and a number of warships have been built there. There is a construction yard also at Trieste. A new coaling and torpedo station is at Teodo, large magazines and stores are at Vallelunga, and the mining establishment is at Ficella. The shipbuilding branch of the navy is under the direction of a chief constructor (Oberster-Ingenieur), assisted by seven constructors, of whom two are of the first class. The engineering and ordnance branches are similarly organized.

*Spain.*—The Spanish dockyards are of considerable antiquity, but of diminishing importance. There is an establishment at Ferrol, another at Cartagena, and a third at Cadiz. They are well equipped in all necessary respects, but are not provided with continuous work. A recent arrangement is the specialization of the yards, Ferrol being designed for larger, and Cartagena for smaller, building work. The ordnance establishment is at Carraca.

*Japan.*—The principal Japanese dockyard, which was established by the Shogunate in 1866, is Yokosuka. French naval constructors and engineers were employed, and several wooden ships were built there. The Japanese took the administration into their own hands in 1875, and have built a number of vessels of small displacement in the yard. The limit of size has been about 5000 tons, but it is intended to enlarge the establishment so that vessels of the first class may ultimately be built there. There is a first-class modern dry dock which will take the largest battleship. About 4000 hands are employed. Shipbuilding would be undertaken to a larger extent but for the fact that nearly all material has to come from abroad. All the important vessels of the Japanese navy have been built in Great Britain, France, Germany, and the United States. Japan has dockyards of lesser importance at Kuré and Sassebo, and a fourth is being established at Maisuru, on the north-west coast of the main island. (J. LD.)

**Dodgson, Charles Lutwidge** ("LEWIS CARROLL") (1832–1898), English mathematician and author.—The literary life of "Lewis Carroll" is familiar to every one, but the private life of Charles Lutwidge Dodgson was retired and practically uneventful. The son of the Rev. Charles Dodgson, vicar of Daresbury, he was born in that village on 27th January 1832. After four years' schooling at Rugby, he matriculated at Christ Church, Oxford, in May 1850; and from 1852 till 1870 held a studentship there. He took his degree in 1854, and the following year was appointed mathematical lecturer at Christ Church, a post he continued to fill till 1881. In 1861 he was ordained. His earliest publications, beginning with *A Syllabus of Plane Algebraical Geometry* (1860) and *The Formulæ of Plane Trigonometry* (1861), were exclusively mathematical; but late in the year 1865 he published, under the pseudonym of "Lewis Carroll," *Alice's Adventures in Wonderland*, a work that was the outcome of his keen sympathy with the imagination of children and their sense of fun. Its success was immediate, and the name of "Lewis Carroll" has ever since been a household word. It was followed (in the "Lewis Carroll" series) by *Phantasmagoria*, in 1869; *Through the Looking-Glass*, in 1871; *The Hunting of the Snark*, 1876; *Rhyme and Reason*, 1883; *A Tangled Tale*, 1885; and *Sylvie and Bruno*, in two parts, 1889 and 1893. A number of anonymous skits on Oxford topics, that appeared between 1865 and 1874, were due to his pen. While "Lewis Carroll" was delighting children of all ages, C. L. Dodgson periodically published mathematical works, such as *An Elementary Treatise on Determinants* (1867), *Euclid, Book V., proved Algebraically* (1874), *Curiosa Mathematica* (1888); and throughout this dual existence Mr Dodgson pertinaciously refused to acquiesce in being publicly identified with "Lewis Carroll." Though the fact of his authorship of the "Alice" books was an open secret, he invariably stated, when occasion called for such a pronouncement, that "Mr Dodgson neither claimed nor acknowledged any connexion with the books not published under his name." He died at Guildford, 14th January 1898. (R. F. S.)

**Dodona.**—The ruins at Dramisos, near Tsacharovista, in Epirus, consisting of a theatre, the walls of a town, and some other buildings, had been conjectured to be those of Dodona by Wordsworth in 1832, but the conjecture was changed into ascertained fact by the excavations of M. Carapanos. In 1875 he made some preliminary investigations; soon after, an extensive discovery of antiquities was made by peasants, digging without authority; and after this M. Carapanos made a systematic excavation of the whole site. The topographical and

architectural results are disappointing, and show either that the site always retained its primitive simplicity, or else that whatever buildings once existed have been very completely destroyed. As M. Carapanos states that he has turned over the whole surface to a considerable depth, he can hardly have failed to bring to light whatever is left.

To the south of the hill, on which are the walls of the town, and to the east of the theatre, is a plateau about 200 yards long and 50 yards wide. Towards the eastern end of this terrace are the scanty remains of a building which can hardly be anything but the temple of Zeus; it appears to have consisted of pronaos, naos or cella, and opisthodomus, and some of the lower drums of the internal columns of the cella were still resting on their foundations. No trace of any external colonnade was found. The temple was about 130 feet by 80 feet. It had been converted into a Christian church, and hardly anything of its architecture seems to have survived. In it and around it were found the most interesting products of excavation—statuettes and decorative bronzes, many of them bearing dedications to Zeus Naïos and Dione, and inscriptions, including many small tablets of lead which contained the questions put to the oracle. Farther to the west, on the same terrace, were two rectangular buildings, which M. Carapanos conjectures to have been connected with the oracle, but which show no distinguishing features.

Below the terrace was a precinct, surrounded by walls and flanked with porticoes and other buildings; it is over 100 yards in length and breadth, and of irregular shape. One of the buildings on the south-western side contained a pedestal or altar, and is identified by M. Carapanos as a temple of Aphrodite, on the insufficient evidence of a single dedicated object; it does not seem to have any of the characteristics of a temple. In front of the porticoes are rows of pedestals, which once bore statues and other dedications. At the southern corner of the precinct is a kind of gate or propylæum, flanked with two towers, between which are placed two coarse limestone drums. If these are *in situ* and belong to the original gateway, it must have been of a very rough character; it is very improbable that they carried, as M. Carapanos suggests, the statuette and bronze bowl by which divinations were carried on.

The chief interest of the excavation centres in the smaller antiquities discovered, which are now placed in M. Carapanos's collection in Athens. Among the dedications, the most interesting historically are a set of weapons dedicated by King Pyrrhus from the spoils of the Romans, including characteristic specimens of the pilum. The leaden tablets of the oracle contain no certain example of a response, though there are many questions, varying from matters of public policy or private enterprise to inquiries after stolen goods.

See *Dodone et ses Ruines*, par Constantin Carapanos. Paris, 1878. For the oracle inscriptions, see E. S. Roberts in *Journal of Hellenic Studies*, vol. i. p. 228. (E. Gr.)

**Dolby.** See Sainton.

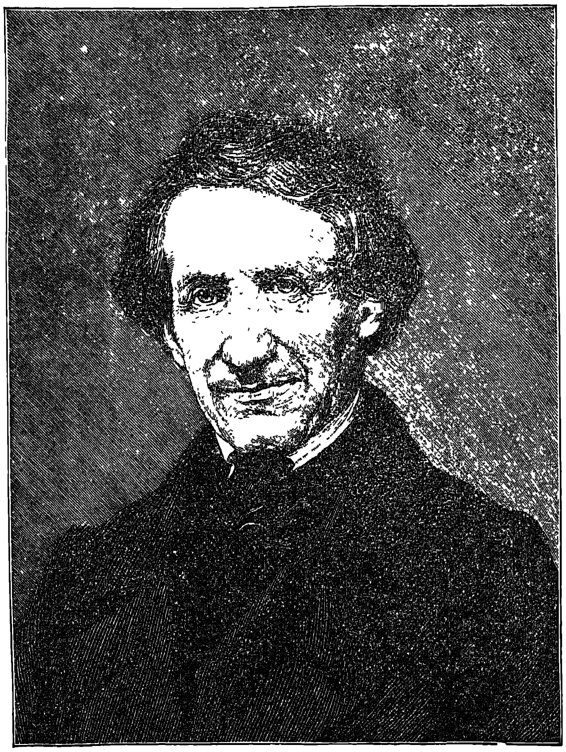
**Dolgelley,** a market-town, railway station, and county town of Merionethshire, Wales, 68 miles south-east by south of Holyhead. There are a parish church and various chapels. There is a free grammar school (1665). The old "Parliament House" has been demolished. Area of urban district, 175 acres. Population (1881), 2455; (1901), 2437. Area of civil parish, 25,375 acres. Population (1881), 3962; (1891), 3785.

**Döllinger, Johann Joseph Ignaz von** (1799–1891), German theologian and Church historian, was born at Bamberg, Bavaria, on 28th February 1799. He came of an intellectual stock, his grandfather and father having both been physicians of eminence and professors of one or other of the branches of medical science. His father was also a man of general literary culture, and celebrated for his power of imparting instruction, though he is said to have been somewhat rough and overbearing in character. The mother of the young Döllinger, too, was a member of a family not undistinguished in intellectual power. The early education of their son was carried out under his father's supervision; and though the stories which have become widely current about the proficiency of Dollinger at an early age in Greek and Latin were denied by the celebrated theologian himself, we may be sure that he was not permitted to be backward in his studies. The elder Döllinger, shortly after his son's birth, was removed to a professorship at Wurzburg. There he came into friendly relations with the well-known philosopher Schelling, a circumstance which doubtless left its stamp for life upon his son.

Young Döllinger mastered the French language very early, and soon conceived an enthusiastic admiration for Napoleon, which lasted until, at about seventeen years of age, he fell in with an account of the treatment of Pope Pius VII. by that great conqueror. At this period he left the gymnasium at Würzburg, to which he had early been sent, and began to study natural philosophy at the university in that city. In 1817 he commenced the study of mental philosophy and philology. He thus laid a basis of sound general knowledge before he pursued the study to which he ultimately devoted himself. This study was theology, which he decided to take up in 1818, because he believed it to lie beneath every other science which could be named. The teaching of theology in Roman Catholic Germany was then passing through a transition stage. But at that moment ecclesiastical history continued to be very ill taught, and young Döllinger resolved to carry on the study of it independently—a resolution which in all probability materially affected his career.

In 1820 he became acquainted with Huber, another fact which, as will be seen, largely influenced his own life as well as that of his friend. On 5th April 1822 he was ordained priest, after studying awhile at Bamberg, and in 1823—at a very early age—he became professor of Ecclesiastical History and Canon Law at Aschaffenburg. Here began his career as author. He then took his doctor's degree, and in 1826 became professor of Theology at Munich, where he spent the rest of his life. About this time Döllinger brought upon himself the animadversion of Heine, who was then editor of a Munich paper. He described the professor's face as the "gloomiest" in the whole procession of ecclesiastics which took place on Good Friday. All shades of Christianity, it is to be remembered, came under the lash of that unsparing satirist. It has sometimes been stated that in his earlier years Döllinger was a pronounced Ultramontane. This does not appear to have been altogether the case; for, very early in his professorial career at Munich, the Jesuits attacked his teaching of ecclesiastical history, and the celebrated Möhler, who afterwards became his friend, on being appealed to, pronounced on the whole in his favour. He also entered into relations with the well-known French Liberal Catholic Lamennais, whose views on the reconciliation of the Roman Catholic Church with the principles of modern society had aroused much suspicion in Ultramontane circles. In 1832 Lamennais, with his friends Lacordaire and Montalembert, visited Germany, and obtained considerable sympathy in their attempts to bring about a modification of the Roman

Catholic attitude to modern problems. Dollinger seems to have regarded favourably the removal, by the Bavarian Government, in 1841, of Professor Kaiser from his chair, because he had taught the infallibility of the Pope. On the other hand, he published a treatise in 1838 against mixed marriages, and in 1843 wrote strongly in favour of requiring Protestant soldiers to kneel at the consecration of the Host when compelled officially to be present at Mass. Moreover, in his work on the "Reformation" (1846–1848) he is very severe on the Protestant leaders, and he also accepts, in his earlier works, the Ultramontane view then current on the practical condition of the Church of England, a view which in later days he found reason to change. Meanwhile he had visited England, where he was well received; and he afterwards travelled in Holland, Belgium, and France, acquainting himself with the condition and prospects of the Roman Catholic Church in those countries. In 1842 he entered into correspondence with the leaders of the Tractarian movement in England, and some interesting letters have been preserved which were exchanged between him and Dr Pusey, Mr Gladstone, and Mr Scott (afterwards Mr Hope Scott). When the last-named joined the Church of Rome he was warmly congratulated by Dollinger on the step he had taken. He, however, much regretted the gradual and very natural trend of his new English allies towards extreme Ultramontane views, of which Archdeacon, afterwards Cardinal, Manning ultimately became an enthusiastic advocate. In 1845 Döllinger was made representative of his University in the Second Chamber of the Bavarian Legislature. In 1847, in consequence of the fall from power in Bavaria of the Abel Ministry, with which he had been in close relations, he was removed from his professorship at Munich, but in 1849 he was invited to occupy the chair of Ecclesiastical History. In 1848, when nearly every throne in Europe was shaken by the spread of revolutionary sentiments throughout the European continent, he was elected delegate to the National German Assembly at Frankfort,—a sufficient proof that at this time he was regarded as no mere narrow and technical theologian, but as a man of wide and independent views. It has been said that his change of relations to the Papacy dated from the Italian war in 1859, but no sufficient reason has been given for this statement. It is far more probable that, like Grosseteste, he had imbibed in early youth an enthusiastic sentiment of attachment to the Papacy as the only centre of authority, and the only guarantee for public order in the Church, but that his experience of the actual working of the Papal system had to a certain extent convinced him how little correspondence there was between his ideal and the reality. He may also have been unfavourably impressed with the promulgation by Pius IX. in 1854 of the dogma of the Immaculate Conception of the Blessed Virgin. But, whatever may have been his reasons, he ultimately became the leader of those who were energetically opposed to any addition to, or more stringent definition of, the powers the Papacy had possessed for centuries. By the year 1863 his position had evidently undergone a change. In that year he invited a number of theologians, amounting to one hundred, to discuss the question which Lamennais and Lacordaire had previously and prematurely raised in France, namely, the attitude that should be assumed by the Roman Catholic Church towards modern ideas. His *The Church and the Churches* (Munich, 1861) dealt to a certain extent with the same question. But his address to the assembled divines in 1863 was, as Professor Woker says (*Internationale Theologische Zeitschrift*, July 1899, p. 459), "practically a declaration of war against the Ultramontane party." He had spoken boldly in favour of freedom for the Church in the Frankfort National Assembly in 1848, but he had found the authorities of his Church claiming a freedom of a very different kind from that for which he had contended. The freedom he claimed for the Church was freedom to manage her affairs without the interference of the State; the adherents of the Papacy desired freedom in order to put a stop to the dissemination of modern ideas. The famous *Syllabus*, recently put forth by Pius IX., had declared war against modern science and progress, and had reproduced the mediæval claims of the Church in a most uncompromising form. The addresses delivered in the Assembly of Divines in 1863 were a declaration in the opposite direction. The Pope for a moment seemed to hesitate, but there could be little doubt what course he would ultimately pursue, and after four days' debate the Assembly was closed at his command. It was in connexion with this question that Döllinger published his *Past and Present of Catholic Theology* and his *Universities Past and Present* (Munich, 1867).



JOHANN JOSEPH IGNAZ VON DÖLLINGER.
*(From a photograph by F. Bruckmann, Münich.)*

We now approach the critical period of Dollinger's life. It was about this time that some of the leading theologians of the Roman Catholic Church, conceiving that the best way of meeting present perils was to emphasize, as well as to define more clearly, the authority of the Pope, advised him to make his personal infallibility a dogma of the Church, and urged strenuously on him the necessity of calling a Council for that purpose. There was considerable opposition in various quarters. Many bishops and divines considered the proposed definition a false one. Others, though accepting it as the truth, declared its promulgation to be inopportune. But the headquarters of the opposition was Germany, and its leader was Döllinger, whose high reputation and vast stores of learning placed him far above any other member of the band of theological experts who now gathered around him. Among them were his intimate friends Friedrich and Huber, in Bavaria. In the rest of Germany he found many supporters, chiefly professors in the Catholic faculty of theology at Bonn: among these were the famous canonist von Schulte, the

learned Reusch, the afterwards celebrated ecclesiastical historian Langen, as well as Reinkens, afterwards bishop of the Old Catholic Church in Germany, Knoodt, and other distinguished scholars. In Switzerland, Professor Herzog, who became Old (or, as it is sometimes called, Christ-) Catholic Bishop in Switzerland, and other learned men supported the movement. Early in 1869 the famous *Letters of Janus* (which were at once translated into English) began to appear. They were written by Dollinger in conjunction with Huber and Friedrich, afterwards professors at Munich. In these the tendency of the *Syllabus* towards obscurantism and Papal despotism, and its incompatibility with modern thought, were clearly pointed out; and the evidence against Papal Infallibility, resting, as the "Letters" asserted, on the Forged Decretals, and accepted without controversy in an age of ignorance, was ably marshalled for the guidance of the Council. When, on 8th December 1869, it had actually assembled, the world was kept informed of what was going on in the *Letters of Quirinus*, written by Döllinger and Huber while the debates of the Council were proceeding. Some of these letters appeared in the German newspapers. An English translation was published by Rivington. Augustin Theiner, the librarian at the Vatican, then in disgrace with the Pope for his outspoken Liberalism, kept his German friends well informed of the course of the discussions. The proceedings of the Council were frequently very stormy, and the opponents of the dogma of Infallibility complained that they were not unfrequently interrupted, and that endeavours were made to put them down by clamour. The dogma was at length carried by a considerable majority of the bishops present, and the rest one by one submitted, Bishops Hefele, of Rottenburg, and Strossmayer, from Croatia, being the last who held out. Döllinger, however, was not to be silenced. He headed a protest by forty-four professors in the University of Munich, and gathered together a Congress at Nuremberg, which met in August 1870 and issued a declaration adverse to the Vatican decrees. An immense ferment took place. In Bavaria, where Döllinger's influence was greatest, the strongest determination to resist the resolutions of the Council prevailed. But the authority of the Council was held by the Archbishop of Munich to be paramount, and he called upon Döllinger to submit. Instead of submitting, Döllinger, on 28th March 1871, addressed a memorable letter to the archbishop, refusing to subscribe the decrees. They were, he said, opposed to Holy Scripture, to the traditions of the Church for the first thousand years, to historical evidence, to the decrees of the General Councils, and to the existing relations of the Roman Catholic Church to the State in every country in the world. "As a Christian, as a theologian, as an historian, and as a citizen," he added, "I cannot accept this doctrine." The reply of the Archbishop of Munich was the proclamation of an excommunication against the disobedient professor. This roused opposition afresh. He was almost unanimously elected rector-magnificus of the University of Munich, and Oxford, Edinburgh, and Marburg Universities conferred upon him the honorary degree of doctor of laws, and Vienna that of philosophy. The Bavarian clergy invited Bishop Loos, the bishop of a Church in Holland which for more than 150 years had existed independent of the Papacy, and had adopted the name of "Old Catholic," to hold confirmations in Bavaria. The offer was accepted, and the bishop was received with triumphal arches and other demonstrations of joy. The three Dutch Old Catholic bishops declared themselves ready to consecrate a bishop, if it were desired. The momentous question was discussed at a meeting of the opponents of the Vatican decrees, and it was resolved to elect a bishop and ask the Dutch bishops to consecrate him. Dollinger, however, voted against the proposition, and withdrew from any further steps towards the promotion of the movement. This was the critical moment in the history of the resistance to the decrees. Had Döllinger, with his immense reputation as a scholar, as a divine, and as a man, allowed himself to be consecrated bishop of the Anti-Vaticanist Church, it is impossible to say how wide the schism would have been. But he declined to initiate a schism. His refusal lost Bavaria to the movement; and the number of Bavarian sympathizers was still further reduced when the seceders, in 1878, allowed their priests to marry, a decision which Döllinger, as was known, sincerely regretted. The Old Catholic Communion, however, was formally constituted, with Reinkens at its head as bishop, and it still continues to exist. Dollinger's attitude to the new community was not very clearly defined, nor indeed very consistent. He did not refuse to meet the Old Catholic leaders in the various Conferences which were held between 1871 and 1875, and was always ready to give his advice, when asked, to the infant community. He remained on the most friendly terms with its members. His addresses on the Reunion of the Churches, delivered at the Bonn Conference of 1872, show that he was by no means hostile to the newly formed communion, in whose interests these Conferences were held. It may be difficult to reconcile the two declarations made by him at different times: "I do not wish to join a schismatic society; I am isolated," and "As for myself, I consider that I belong by conviction to the Old Catholic community." The latter declaration was made some years after the former, in a letter to Pastor Widmann. The nearest approach to a reconciliation of the two statements would appear to be that while, at his advanced age, he did not wish to assume the responsibility of being head of a new denomination, formed in circumstances of exceptional difficulty, he was unwilling to condemn those who were ready to hazard the new departure. "By conviction" he belonged to the Old Catholics, but practically he took no active part in their proceedings. Yet at least he was ready to meet the leaders of the Old Catholic Church, to address them, and to discuss difficult problems with them. In 1874, and again in 1875, he presided over the Reunion Conferences held at Bonn and attended by leading ecclesiastics from the British Isles and from the Oriental Church, among whom where Bishop Christopher Wordsworth of Lincoln; Bishop Harold Browne of Ely; Lord Plunket, archbishop of Dublin; Lycurgus, archbishop of Syros and Tenos; Canon Liddon; Professor Ossinine of St Petersburg, and other eminent divines. At the latter of these two Conferences, when Döllinger was seventy-six years of age, he delivered a series of marvellous addresses in German and English, in which he discussed the state of theology on the Continent, the Reunion question, and the religious condition of the various countries of Europe in which the Roman Catholic Church held sway. Not the least of his achievements on this occasion was the successful attempt, made with extraordinary tact, ability, knowledge, and perseverance, to induce the Orientals, Anglicans, and Old Catholics present to accept a formula of concord, drawn from the writings of the leading theologians of the Greek Church, on the long-vexed question of the Procession of the Holy Spirit. This result having been attained, he passed the rest of his days in retirement, emerging sometimes from his retreat to give addresses on theological questions, and also writing, in conjunction with his friend Reusch, his last book, *Geschichte der Moralstreitigkeiten in der Römisch-Katholischen Kirche seit dem sechzehnten Jahrhundert, mit Beiträgen zur Geschichte und Charak-*

*teristik des Jesuitenordens* (Nordlingen, 1889), in which he deals with the moral theology of St Alphonso de Liguori. He died in Munich, on the 14th January 1890, at the age of ninety-one. In his latest moments he refused the sacraments at the hands of a Roman Catholic priest, and the last offices were performed by his faithful and attached friend Professor Friedrich.

In addition to the works referred to in the foregoing sketch, we may mention *The Eucharist in the First Three Centuries* (Mainz, 1826), a *Church History* (Ratisbon, 1836–1838), *Hippolytus and Callistus* (Ratisbon, 1854), *First Age of Christianity* (1860). His *Lectures on the Reunion of the Churches* and on *The Vatican Decrees* have also been published. Both these last have been translated into English. (J. J. L*.)

**Dolnja-Tuzla,** capital of the district of Tuzla in the province of Bosnia, Austria-Hungary, beautifully situated in a mountainous district on the right bank of the Julla, at the terminus of a branch railway line from Doboj, from which it is 38½ miles south-east. From a very ancient date it has had an important connexion with the salt industry, being known by the Romans as *Ad Salinas*, while in the Middle Ages it was known as Sou or Sow, the capital of the salt district. It is the seat of an Orthodox bishop. A high school (*obergymnasium*) was opened in 1898. Of late, attempts have been made to develop the salt industry. There are coal-mines in the neighbourhood, and there is also a trade in corn, cattle, swine, and horses. An ammonia soda factory has been opened near the town. The population is 10,227, all Mahommedans, including a permanent colony of gypsies.

**Dominica,** the largest island in the colony of the Leeward Islands, of which it forms one of the five presidencies. The temperature ranges from 78° to 86° in the hot season (from August to October), and from 72° to 84° during the cooler months. In spite of the heavy rainfall (varying in different parts of the island from 50 to 162 inches per annum) the atmosphere is dry, the rain sinking into the porous soil very rapidly. The climate, though hot on the low ground, is decidedly healthy for the tropics, and no case of yellow fever has occurred since 1850. In 1871 the census return gave 27,178 inhabitants; that of 1891 gave 26,841 (335 white, 6806 coloured, and 19,700 black). In 1900 the population was estimated at 30,000. The value of the imports for 1874 was £56,714; for 1899, £66,433; while for 1874 exports were £67,720; and for 1899, £64,070. The principal exports in 1899 were limes and lime-juice, cacao, and sugar. Other products are coffee, cocoanuts, nutmegs, cloves, cinnamon, and other spices, oranges, bananas, pineapples, and almost all tropical fruits. The tonnage of the vessels entered and cleared during 1898 was (steam, 447,324; sailing, 9674) 456,998, of which 451,136 was British and 5862 foreign. The revenue for 1874 was £15,022; for 1898, £24,570. The expenditure for 1874 was £17,456; for 1898, £24,648. The manufactures of the island include sugar, lime-juice, and bay-oil; there are many peasant proprietors and metayers. In religion, Roman Catholics predominate. Education in the primary schools is free and by law compulsory. The Cambridge Local Examinations are held in the colony. The French patois, a result of French occupation from time to time, is the predominant language of the peasant class, but English is understood by many, and its general use is increasing. In 1898 the local legislature, in consideration of pecuniary assistance from Great Britain, passed an Act abrogating the semi-elective constitution and providing for a Legislative Council of 12 members,—6 official and 6 unofficial,—all nominated by the Governor.

**Don, Province of the** (Russian, *Donskaya Oblast*), a province of S.E. Russia. The governments of Voronezh, Kharkoff, and Ekaterinoslav lie to the west, the Sea of Azov to the south-west, the Caucasian provinces Kubañ and Stavropol to the south, Astrakhan and Saratov to the east. Area, 63,532 square miles. Population (1897), 2,575,818. It almost entirely belongs to the domain of the South Russian prairies, having the character of higher, ravinated plains in the north (Donetskiy Kryazh), west, and south-west, while in the south-east, towards the Manych, they belong to the type of the dry Aral-Caspian steppes (Zadonsk Steppe), dotted with salt lakes. The geological formation consists of Carboniferous sandstones, clay slates and limestones containing anthracite and coal; Cretaceous marls, chalk, sandstone, and green sands—chalk cliffs accompanying the Don for 200 miles of its course; and Miocene limestones and clays. Coal is extracted in the south-west, also some chalk, slate, limestone, and salt. The surface, especially west of the Don, is fertile black earth, interrupted here and there, and especially in the Zadonsk Steppe, with clay impregnated with salt. The province is watered by the Don and its tributaries, of which the Donets, Chir, and Mius are on the left bank, Khoper and Medvyeditsa on the right. The Don is navigable for more than 650 miles below Voronezh, attaining, after its junction with the Sosna, a width of 250 to 300 yards, and 600 yards in its lower course. Before entering the Sea of Azov it sends it a long navigable branch, the Aksai, and in its delta it divides into some thirty minor branches (*ghirla*). The Don is a very important artery of navigation for S.E. Russia; and as it approaches very near to the Volga at Kalach, which is connected by a 40-miles railway with Tsaritsyn on the Volga, goods shipped down or up the latter (corn, naphtha, timber, &c., 450,000 tons every year) are transported to the Don in order to be shipped to Rostov and Taganrog for export or to be sent up the river to Central Russia; at the same time goods imported to the last-named ports are brought to Kalach and transported to the Volga to be sent up this river. Moreover, in its upper parts the Don is connected by a canal with the Oka, tributary of the Volga. Nearly 550,000 tons of various goods are shipped every year in the basin of the Don, the chief ports being Rostov, Taganrog on the Sea of Azov, Kalach, and Uryupina. The climate is continental and dry, the average temperatures being:—year 43° Fahr., January 13°, July 72°, at Uryupina (50° 48′ N.; alt. 92 ft.); and year 48° Fahr., January 21°, July 73°, at Taganrog. The yearly amount of rain is only 13·4 and 17·5 inches respectively. Forests cover only 2 per cent. of the area.

Nearly one-half of the population (966,869, of whom 483,174 were men and 483,695 women, out of a total population which was 2,078,878 in 1891) belong to the Cossacks. The great bulk of the population belong to the Greek Orthodox Church; there were, moreover, in 1891, 123,039 Nonconformists, 43,714 other Christians, 15,154 Jews, 2478 Mussulmans, and 29,550 Lamaite Kalmyks, who also belonged to the Cossack *Voisko*. The Cossacks own 23,485,640 acres of land and have a reserve of 6,210,000 acres, more than half of which is rented. Provincial self-government was introduced in 1879, but withdrawn three years later. The province is well provided with schools, especially on the Cossack territory.

Agriculture is the main occupation, but the crops vary very much from year to year on account of want of rain (from 3,524,000 to 8,420,000 quarters). Vine-growing on a large scale and tobacco culture are carried on in the south. Cattle-breeding is important, there being 532,688 horses (some very fine breeds), 1,889,600 horned cattle, and 3,093,600 sheep. Rich fisheries at the mouth of the Don. Nearly 13,000 persons are engaged in coal-mining, 580,000 tons of anthracite and 700,000 tons of coal being extracted yearly. The yearly production of all factories attains £2,261,000, the chief of them being ironworks, and tobacco factories. The exports are considerable, consisting chiefly of corn, cattle, horses, sheep, wine, fish, and hides.

The province is under the Ministry of War, and is divided into nine districts: Donets (chief town Kamenskaya, 23,576 inh.), First Don (Konstantinovskaya, 8808 inh.), Second Don (Nizhne-Chirskaya, 15,196 inh.), Rostov (chief town Rostov-on-the-Don,

119,889 inh.), Salsky (Velikoknyazheskaya village), Taganrog (chief town same name, 51,965 inh.), Ust-Medvyeditsa (chief town same name, 14,520 inh.), Khoper (Uryupinskaya, 9612 inh.), Cherkassky (chief town Novocherkassk, capital of province, 52,005 inh.). Many of the Cossack villages (*stanitsas*) are very populous. (P. A. K.)

**Don Benito,** a town of Spain in the province of Badajoz, 62 miles east of Badajoz by rail. Population in 1897, 15,863. It is a prosperous, busy place, with an active trade in wheat, wine, oil, and fruit. There are brandy distilleries, flour-mills, and soap, linen, jute, and cloth factories. Public buildings include a theatre and two casinos.

**Doncaster,** a municipal and quarter sessions borough and market-town in the Doncaster parliamentary division of Yorkshire, England, on the Don, 156 miles north-east of London by rail. Besides a Wesleyan school, there have been erected Primitive Methodist, Presbyterian, Baptist, Congregational, and Wesleyan chapels; also Roman Catholic and other churches. A free library and school of science and art, public baths, gas-works, electricity works, corn exchange, markets, slaughter-houses, and cold stores have been built; and the water-works constructed at Thrybergh in 1880 (£170,000) have been augmented to more than twice their capacity of supply by a joint scheme undertaken in partnership with Sheffield and Rotherham; electric trams running from the borough into adjoining suburbs are in course of construction; the old opera-house has been taken down and a new one erected near the railway station, and the Yorkshire institution for deaf mutes enlarged. The racecourse accommodation has been extended by the formation of the Sandall mile course and the erection of additional permanent stands. The Great Northern Railway Company's locomotive and carriage works employ between 5000 and 6000 hands. Area, 1695 acres. Population (1881), 21,139; (1901), 28,928.

**Donchery,** an ancient town and railway station, in the arrondissement of Sedan, department of Ardennes, France, 3 miles west of Sedan, on the Meuse. A sanguinary battle between the French and Bavarians was fought here on the left bank of the Meuse, 31st August 1870, and two days later, at the Château de Bellevue, Napoleon surrendered his sword to the king of Prussia; and terms of capitulation for Sedan were agreed on. Population (1901), 1915.

**Donegal,** a maritime county of Ireland, province of Ulster.

*Area and Population.*—The area of the administrative county in 1900 was 1,190,268 acres, of which 220,864 were tillage, 422,862 pasture, 995 fallow, 5890 plantation, 102,465 turf-bog, 28,614 marsh, 346,289 barren mountain, and 62,289 water, roads, fences, &c. The new administrative county under the Local Government (Ireland) Act, 1898, is identical with the old judicial county. The population in 1881 was 206,035, and in 1891, 185,635, of whom 91,478 were males and 94,157 females, divided as follows among the different religions:—Roman Catholics, 154,893; Protestant Episcopalians, 21,884; Presbyterians, 18,055; Methodists, 2006; and other denominations, 797. The decrease of population between 1881 and 1891 was 9·90 per cent. The average number of persons to an acre was ·16. Of the total population, 180,844 inhabited the rural districts, being an average of 181 persons to each square mile under crops and pasture. The population in 1901 was 173,625 (Roman Catholics, 134,999; Protestant Episcopalians, 19,907; Presbyterians, 16,221; Methodists, 1795; others, 703), being a decrease of 6·5 per cent. The following table gives the degree of education in 1891:—

| | Males. | Females. | Total. | Percentage. | | |
|---|---|---|---|---|---|---|
| | | | | R. C. | Pr. Ep. | Presb. |
| Read and write | 47,464 | 45,304 | 92,768 | 48·8 | 73·6 | 81·3 |
| Read only | 10,486 | 11,981 | 22,467 | 13·9 | 12·8 | 11·0 |
| Illiterate | 24,175 | 27,838 | 52,013 | 37·3 | 13·6 | 7·7 |

In 1881 the percentage of illiterates among Roman Catholics was 47·8. In 1891 there were 7 superior schools with 154 pupils (27 Roman Catholics and 127 Protestants), and 424 primary schools with 20,747 pupils (14,648 Roman Catholics and 6099 Protestants). The number of pupils on the rolls of the national schools on 30th September 1899 was 30,016, of whom 23,183 were Roman Catholics and 6833 Protestants. The following table gives the number of births, deaths, and marriages in various years:—

| Year. | Births. | Deaths. | Marriages. |
|---|---|---|---|
| 1881 | 4519 | 2802 | 682 |
| 1891 | 3900 | 2982 | 674 |
| 1899 | 3785 | 2512 | 712 |

In 1899 the birth-rate per 1000 was 20·4, and the death-rate 13·5; the rate of illegitimacy was 1·8 per cent. of the total births. The total number of emigrants who left the county between 1st May 1851 and 31st December 1899 was 121,429, of whom 64,848 were males and 56,581 females. The chief towns in the county are Ballyshannon, Letterkenny, and Donegal.

*Administration.*—The county is divided into four parliamentary divisions, north, south, east, and west, the number of registered electors in 1900 being respectively 8095, 8370, 7950, and 9475. The ratable value in 1900 was £304,121. By the Local Government (Ireland) Act, 1898, the fiscal and administrative duties of the grand jury and (to a less extent) of other bodies were transferred to a county council, urban and rural district councils were established, and under that Act the county now comprises 2 urban and 10 rural sanitary districts.

*Agriculture.*—The following tables give the acreage under crops, including meadow and clover, and the amount of live-stock in 1881, 1891, 1895, and 1900:—

| Year. | Wheat. | Oats. | Barley, Rye, and Beans. | Potatoes. | Turnips. | Other Green Crops. | Flax. | Meadow and Clover. | Total. |
|---|---|---|---|---|---|---|---|---|---|
| 1881 | 671 | 93,989 | 3189 | 48,666 | 14,797 | 4343 | 11,844 | 53,989 | 231,488 |
| 1891 | 468 | 90,627 | 2820 | 43,340 | 18,778 | 4375 | 5,093 | 66,055 | 231,556 |
| 1895 | 219 | 87,725 | 2460 | 42,446 | 19,267 | 4223 | 7,645 | 68,350 | 232,235 |
| 1900 | 283 | 82,568 | 1721 | 39,725 | 18,552 | 4071 | 6,816 | 67,128 | 220,864 |

In 1899 the total value of the cereal and other crops was estimated by the Registrar-General at £1,569,253. The number of acres under pasture in 1881 was 380,510; in 1891, 410,259; and in 1900, 422,862.

| Year. | Horses and Mules. | Asses. | Cattle. | Sheep. | Pigs. | Goats. | Poultry. |
|---|---|---|---|---|---|---|---|
| 1881 | 23,762 | 2500 | 178,286 | 202,885 | 35,968 | 3702 | 706,797 |
| 1891 | 23,224 | 2265 | 164,844 | 147,894 | 22,885 | 3118 | 675,700 |
| 1895 | 23,939 | 2116 | 180,954 | 183,212 | 34,514 | 2855 | 762,652 |
| 1900 | 22,511 | 3096 | 186,324 | 194,707 | 27,471 | 2916 | 867,492 |

The number of milch cows in 1891 was 65,264, and in 1900, 66,335. It is estimated that the total value of cattle, sheep, and pigs in 1899 was £2,709,468. In 1900 the number of holdings not exceeding 1 acre was 1573; between 1 and 5, 2882; between 5 and 15, 10,399; between 15 and 30, 8432; between 30 and 50, 4037; between 50 and 100, 3161; between 100 and 200, 1026; between 200 and 500, 344; above 500, 97—total, 31,951. The number of loans issued (the number of loans being the same as the number of tenants) under the Land Purchase Acts, 1885, 1891, and 1896, up to 31st March 1900, was 1207, amounting to £334,948. The number of loans for agricultural improvements sanctioned under sect. 31 of the Land Act, 1881, between 1882 and 1900, was 280, and the amount issued was £17,943. The total amount issued on loan for all classes of works under the Land Improvement Acts, from the commencement of operations in 1847 to 31st March 1900, was £190,129.

*Fisheries.*—In the deep-sea and coast fishery districts of Killybegs, Gweedore, and Rathmullen the number of vessels registered in 1899 was 678, employing 2929 men and boys. The number of persons employed in the salmon-fishery districts of Ballyshannon and Letterkenny in the same year was 988. (W. H. Po.)

**Doobaunt,** a river of Mackenzie and Keewatin districts, Canada. It rises in Wholdiah Lake, in 104° 20′ W. long. and 60° 15′ N. lat., and flows northward to its confluence with the Thelew river, and thence eastward to Chesterfield Inlet, an arm of Hudson Bay. It passes through several lake-expansions, including Doobaunt Lake,

ILLUSTRATIONS FOR DANTE'S *INFERNO.* BY GUSTAVE DORÉ.

with an area of 1700 square miles and an altitude of 500 feet above the sea; Aberdeen, altitude, 130 feet; and Baker, 30 feet above the sea. Discovered in 1770 by Samuel Hearne, the Doobaunt was explored by J. B. Tyrrell in 1893, and the Thelew by David Hanbury in 1899.

**Dorchester,** a municipal borough, market-town, and county town in the southern parliamentary division (since 1885) of Dorsetshire, England, on the Frome, 120 miles south-west by west from London by rail. Recent erections are the Dorset County Museum, an isolation hospital, and a statue to the Dorsetshire poet, William Barnes (1889). The borough gardens were bought and laid out by the corporation in 1896. Area, 1653 acres. Population (1881), 7567; (1901), 9458.

**Dordogne,** a department in the south-west of France, watered by the Dordogne.

Area, 3561 square miles, distributed among 47 cantons and 585 communes. From 492,205 in 1886 the population decreased to 448,545 in 1901. Births in 1899, 9377, of which 361 illegitimate; deaths, 9831; marriages, 3777. There were, in 1896, 1220 schools, with 62,000 pupils, and 15 per cent. of the population was illiterate. The area under cultivation in 1896 comprised 1,887,952 acres, of which 1,104,600 acres are arable land, 494,229 acres are woodland, and 54,365 acres vineyards. The wheat crop of 1899 amounted to the value of £1,980,300; maize returned £173,800; potatoes, £630,500; mangold-wurzel, £155,000; the natural pastures, £604,000. Hemp, yielding in 1899 altogether a value of £3940, and tobacco £85,800, are also cultivated with success. The produce of the vines in 1899 amounted to the value of £680,000; of chestnuts, £92,000; of walnuts, £83,000. The live-stock in 1898 comprised 16,290 horses, 21,650 asses, 201,900 cattle, 399,000 sheep, 175,750 pigs, and 9150 goats. The mining industry turned out in 1898 2500 metric tons of lignite, 1200 tons of peat, and 1300 tons of iron. Building stone is quarried in abundance, and the metallurgic industry yielded in 1896 £32,000 worth of iron. With the exception of paper manufacture, the other industries are in a backward state. The capital town, Périgueux, has a population of 31,400.

**Dordrecht** or **Dordt,** one of the oldest towns in the province of South Holland, Netherlands, 10 miles south-east of Rotterdam, on the main line between that town and Antwerp, at the junction of the Old and New Maas (Noord), the Merwede, and the waterway to Zeeland. As Tiel was deprived of a portion of its trade by Dordrecht, so the trade of Dordrecht has in part been diverted to Rotterdam. The shipping trade of the town, however, still remains very considerable, 2600 ships passing weekly. The trade is mainly in wood (imported from Germany, Scandinavia, and America), salt, oil-seeds, wine, grain, and petroleum. The town has numerous engineering works, sawmills, distilleries, stained-glass works, and shipbuilding yards. The Gothic Greek church was successfully restored in 1882, the theatre of the *Musis Sacrum* enlarged in 1885, and a new theatre erected in 1889. Population (1900), 34,386.

**Doré, Louis Auguste Gustave** (1832–1883), French artist, the son of a civil engineer, was born at Strassburg on 6th January 1832. In 1848 he came to Paris and secured a three years' engagement on the *Journal pour Rire*. His facility as a draughtsman was extraordinary, and among the books he illustrated in rapid succession were Balzac's *Contes Drolatiques* (1855), Dante's *Inferno* (1861), *Don Quixote* (1863), *The Bible* (1866), *Paradise Lost* (1866), and the works of Rabelais (1873). He painted also many large and ambitious compositions of a religious or historical character, and made some success as a sculptor, his statue of Alexandre Dumas in Paris being perhaps his best-known work in this line. He died 25th January 1883.

**Dorking,** a market-town in the Reigate parliamentary division of Surrey, England, on the Mole, 26 miles south of London by rail. Recent erections are the Roman Catholic church (rebuilt), a drill hall, and a literary institute. Area of urban district, 1347 acres. Population (1881), 6328; (1901), 7670. Area of old civil parish, now comprising both Dorking and Dorking Rural, 10,028 acres. Population (1881), 9577; (1901), 11,410.

**Dornbirn,** a township in the district of Feldkirch, Vorarlberg (Austria), on the Vorarlberg line of the Austrian State Railway. A busy industrial centre, the regulated Dornbirner Ach furnishing motive-power for several factories. The industries include the manufacture of machinery, hardware and metal goods, jewellery, cotton spinning, weaving, and printing, and a model dairy farm. Population (1890), 10,678; (1900), 13,052.

**Dorner, Isaac August** (1809–1884), German Lutheran theologian, was born at Neuhausen-ob-Eck, in Würtemberg, 20th June 1809. He studied at Tübingen, and then returned to his native village and assisted his father in the pastorate of the parish. He afterwards visited Holland and England, in order to investigate the condition of Protestantism in those countries. He was made professor of Theology at Tübingen in 1838, at Kiel in 1839, at Königsberg in 1840, of the Protestant Faculty of Theology at Bonn in 1847. Thence he removed to Berlin. Though a student at Tübingen, he did not embrace the well-known views on theology and early Church history which originated at that university. In his famous *History of the Doctrine of the Person of Christ*, in which he investigated with remarkable skill and clearness the teaching of the leading divines of the first five centuries, he has left an indelible record of his ability and research. He was a voluminous writer, and among his most important works are a *History of Protestant Theology* (1867), and his *System of Christian Doctrine* (1879–81), and *System of Christian Morals* (1888). He also contributed to Herzog's well-known *Encylopädie für Protestantische Theologie*. For many years he assisted in editing the *Jahrbücher für Deutsche Theologie*. He died at Wiesbaden, 8th July 1884. (J. J. L*.)

**Dornoch,** a royal and parliamentary burgh (Wick group) and the county town of Sutherlandshire, Scotland, on the Dornoch Firth, 7 miles south-south-east of the Mound station on the Highland Railway. A light railway between the Mound and Dornoch is being constructed. The tower of the cathedral, built by Bishop Gilbert de Moravia (1222–45), remains; the main body was rebuilt in 1837, and is used as the parish church. On the site of the Bishop's Palace, of which the tower is still standing, are the county buildings. There are well-known golf links and a public library. Population (1881), 497; (1901), 624.

**Dorohoi,** a town in Rumania, and chief town of the district bearing the same name, about 80 miles north-west of Jassy, on the river Shiska, tributary of the Pruth. It has an extensive transit trade in the products of Northern Europe. The Church of St Nicholas, built by Stephen the Great in the 15th century, is remarkable. The annual fair held on 12th June is important. Population, of which between 50 and 60 per cent. are Jews (1900), 12,701.

**Dorpat.** See YURIEV.

**Dorsetshire,** a south-eastern county of England, bounded S. and S.W. by the English Channel, W. by Devon, N.W. by Somerset, N.E. by Wilts, and E. by Hampshire.

*Area and Population.*—The area of the ancient and administra-

tive county, as given in the census returns, is 632,272 acres, or 988 square miles. The population in 1881 was 190,969, and in 1891 was 194,517, of whom 94,735 were males and 99,782 females, the number of persons per square mile being 197, and of acres to a person 3·25. Since 1891 the area of the administrative county has undergone certain changes. In 1895 the parishes of Goathill, Poyntington, Sandford-Orcas, Seaborough, and Trent were transferred from Somerset to Dorset, and the parish of Wambrook from Dorset to Somerset, and in 1896 the parishes of Chardstock and Hawkchurch were transferred from Dorset to Devon. The area of the registration county is 616,403 acres, with a population in 1891 of 188,995, of whom 69,216 were urban, and 119,779 rural. Within this area the increase of population between 1881 and 1891 was 2·17 per cent. Between 1881 and 1891 the excess of births over deaths was 22,388, but the increase in resident population was only 4023. In 1901 the population was 202,962. The following table gives the numbers of marriages, births, and deaths, with the number of illegitimate births, in 1880, 1890, and 1898:—

| Year. | Marriages. | Births. | Deaths. | Illegitimate Births. | |
|---|---|---|---|---|---|
| | | | | Males. | Females. |
| 1880 | 1214 | 5508 | 3122 | 134 | 128 |
| 1890 | 1332 | 4786 | 2970 | 100 | 107 |
| 1898 | 1371 | 4852 | 2973 | 101 | 89 |

The number of marriages in 1899 was 1319, of births 4807, and of deaths 3144.

The following table shows the marriage, birth, and death rates per 1000 of the population, with the percentage of illegitimate births, for a series of years:—

| | 1870-79. | 1880. | 1880-89. | 1890. | 1888-97. | 1898. |
|---|---|---|---|---|---|---|
| Marriage-rate | 13·7 | 13·1 | 13·4 | 14·1 | 13·9 | 14·3 |
| Birth-rate | 29·5 | 29·6 | 28·1 | 25·4 | 26·4 | 25·4 |
| Death-rate | 17·8 | 16·8 | 16·3 | 15·7 | 15·7 | 15·5 |
| Percentage of illegitimacy | 5·2 | 4·8 | 4·8 | 4·3 | 4·5 | 3·9 |

Both the birth-rate and the death-rate are much below the average for England. In 1891 there were in the county 771 natives of Scotland, 1240 natives of Ireland, and 396 foreigners.

*Constitution and Government.*—The ancient county is divided into four parliamentary divisions, but has no parliamentary borough. The administrative county contains thirteen towns and urban districts: Blandford Forum (3649), Branksome (8095), Bridport (5710), Dorchester (9458), Lyme Regis (2095), Poole (19,461), Portland (15,262), Shaftesbury (2027), Sherborne (5753), Swanage (3384), Wareham (2003), Weymouth and Melcombe Regis (19,831), Wimborne Minster (3696). Dorsetshire is in the western circuit, and assizes are held at Dorchester. The boroughs of Bridport, Dorchester, Lyme Regis, Poole, and Weymouth and Melcombe Regis have separate commissions of the peace, and the borough of Poole has in addition a separate court of quarter sessions. The ancient county, which is almost entirely in the diocese of Salisbury, contains 254 entire ecclesiastical parishes or districts and parts of five others.

*Education.*—The number of elementary schools in the county on 31st August 1899 was 278, of which only 25 were board, and 253 were voluntary schools, the latter including 234 National Church of England schools, 3 Wesleyan, 7 Roman Catholic, and 9 "British and other." The average attendance at board schools was 3301, and at voluntary schools 24,855. The total school board receipts for the year ended 29th September 1899 were over £10,035. The income under the Agricultural Rates Act was over £632.

*Agriculture.*—About three-fourths of the area of the county is under cultivation, and of this nearly five-eighths is in permanent pasture, while there is, in addition, about 26,000 acres in hill pasturage. Nearly 38,000 acres are under woods. Of the green crops, wheat, barley, and oats occupy an almost equal acreage; but turnips are grown on nearly three-fourths of the acreage under green crops. The following table gives the main divisions of the cultivated area at intervals of five years from 1880:—

| Year. | Total Area under Cultivation. | Corn Crops. | Green Crops. | Clover. | Permanent Pasture. | Fallow. |
|---|---|---|---|---|---|---|
| 1880 | 485,857 | 105,113 | 58,054 | 52,239 | 262,427 | 7766 |
| 1885 | 491,123 | 97,206 | 59,104 | 52,157 | 277,503 | 5026 |
| 1890 | 493,321 | 91,851 | 53,889 | 51,556 | 291,818 | 3903 |
| 1895 | 487,296 | 82,299 | 50,728 | 49,711 | 299,600 | 4503 |
| 1900 | 481,430 | 83,137 | 49,227 | 48,933 | 299,312 | 2678 |

The following table gives particulars regarding the principal live-stock during the same years:—

| Year. | Total Horses. | Total Cattle. | Cows or Heifers in Milk or in Calf. | Sheep. | Pigs. |
|---|---|---|---|---|---|
| 1880 | 16,192 | 76,049 | 47,791 | 463,864 | 37,857 |
| 1885 | 15,794 | 91,202 | 54,675 | 460,371 | 47,790 |
| 1890 | 15,970 | 89,017 | 53,834 | 418,945 | 63,556 |
| 1895 | 16,425 | 83,071 | 52,192 | 370,947 | 66,211 |
| 1900 | 15,588 | 87,904 | 53,620 | 360,491 | 50,930 |

*Industries and Trade.*—According to the annual report for 1898 of the chief inspector of factories and workshops (1900), the total number of persons employed in factories and workshops in 1897 was 7994, as compared with 7950 in 1896. Non-textile factories employed 3820, of whom 1080 were employed in the manufacture of machines, appliances, conveyances, or tools. Paper is manufactured, and ships and yachts are built at Poole. Of the 3347 persons employed in workshops, 1182 were employed in the clothing industries. The number of persons employed in mines and quarries in 1899 was 2038. Limestone and potter's and other clay are dug in increasing quantities, and the famous Purbeck marble and Portland freestone are more and more in demand. The amount of limestone dug in 1898 was 519,214 tons, and of clay 148,184 tons. There are no returns regarding the Portland stone.

There are numerous fishing stations along the coast. The fishing is generally prosecuted within 3 miles of the shore. There are some oyster beds near Poole. The total fish landed in 1899 amounted to 11,305 cwt., valued at £8143.

**Dortmund,** a town of Prussia, province of Westphalia, 50 miles east by north from Düsseldorf. Since the abolition of the walls in 1872 and the conversion of their site into promenades, the town has rapidly assumed a modern appearance. The 13th-century town-hall, with the adjacent Bread House, was thoroughly restored in 1899; the basement of the former contains the municipal antiquarian museum. The post office (1895), synagogue (1898), Roman Catholic church of Our Lady, the provincial law courts, the municipal infirmary, the monuments of the war of 1870–71 (1881) and Bismarck (1899), and the Emperor William Park, with a bronze statue of the Emperor William I. (1894) by Schilling, and a bronze statue of the Emperor Frederick III. (1898), deserve mention. But the real interest of Dortmund centres in her industries—iron, coal, beer, and bricks. Whereas in 1860 the output of the Dortmund coal-field was under 4½ million tons (valued at £1,362,300), in 1870 it had increased to over 11⅓ millions (£3,353,450), in 1880 to close upon 22½ million tons (£5,147,700), in 1890 to approximately 35½ million tons (£14,122,100), and in 1897 to 48½ million tons.[1] During the same period, *i.e.*, from 1860 to 1897, the number of workmen employed in the coal-mines increased from 28,460 to 185,640. The chief products of the iron furnaces, forges, foundries, and other works are mining plant, wire-ropes, implements and machinery, safes, and sewing machines. One firm alone employs nearly 8000 workmen. In addition to the above there are several flour and saw mills. In connexion with the Dortmund-Ems Canal a space of 360 acres has been set apart at Dortmund for docks, and in 1899 four basins, each 43 acres in area and 8⅙ feet minimum depth, were already constructed. Population (1885), 78,435; (1890), 89,663; (1895), 111,232; (1900), 142,418.

**Dost Mahommed Khan** (1793–1863), founder of the dynasty of the Barakzai in Afghanistan, was born in 1793. His elder brother, the chief of the Barakzai, Fati Khan, took an important part in raising Mahmud to the sovereignty of Afghanistan in 1800 and in restoring him to the throne in 1809. That ruler repaid his services by causing him to be assassinated in 1818, and thus incurred the enmity of his tribe. After a bloody conflict Mahmud was deprived of all his possessions but Herat, the rest of his dominions being divided among Fati Khan's brothers. Of these Dost Mahommed received for his share Ghazni, to which in 1826 he added Kabul, the richest of the Afghan provinces. From the commencement of his reign he found himself involved in disputes with Ranjit Singh, the Sikh ruler, who used the dethroned Saduzai prince, Shuja-ul-Mulk, as his instrument. In 1834 Shuja made a last attempt to recover his kingdom. He was defeated by Dost Mahommed under the walls of Kandahar, but Ranjit Singh seized the opportunity to annex Peshawar. The recovery of this fortress became the Afghan Amir's great concern. Rejecting overtures from Russia, he endeavoured to form an alliance with England, and welcomed Alexander Burnes to Kabul in 1837. Burnes, however, was unable to prevail on the Governor-General, Lord Auckland, to respond to the Amir's advances. Dost Mahommed was enjoined to abandon the attempt to recover Peshawar, and to place his foreign policy under British guidance. In return he was only promised protection from Ranjit Singh, of whom he had no fear. He replied by renewing his relations with Russia, and in 1838 Lord Auckland set the British troops in motion against him. In March 1839 the British force under Sir Willoughby Cotton advanced through the Bolan Pass, and on the 26th April it reached Kandahar. Shah Shuja was proclaimed Amir, and entered Kabul on 7th August, while Dost Mahommed sought refuge in the wilds of the Hindu Kush. Closely followed by the British, Dost was driven to extremities, and on 4th November 1840 surrendered as a prisoner. He remained in captivity during the British occupation, during the disastrous retreat of the army of occupation in January 1842, and until the recapture of Kabul in the autumn of 1842. He was then set at liberty, in consequence of the resolve of the British Government to abandon the attempt to intervene in the internal politics of Afghanistan. On his return from Hindustan Dost Mahommed was received in triumph at Kabul, and set himself to re-establish his authority on a firm basis. From 1846 he renewed his policy of hostility to the British and allied himself with the Sikhs; but after the defeat of his allies at Gujarat on 21st February 1849 he abandoned his designs and led his troops back into Afghanistan. In 1850 he conquered Balkh, and in 1854 he acquired control over the southern Afghan tribes by the capture of Kandahar. On 30th March 1855 Dost Mahommed reversed his former policy by concluding an offensive and defensive alliance with the British Government. In 1857 he declared war on Persia in conjunction with the British, and in July a treaty was concluded by which the province of Herat was placed under a Barakzai prince. During the Indian Mutiny Dost Mahommed punctiliously refrained from assisting the insurgents. His later years were disturbed by troubles at Herat and in Bokhara. These he composed for a time, but in 1862 a Persian army, acting in concert with Ahmed Khan, advanced against Kandahar. The old Amir called the British to his aid, and, putting himself at the head of his warriors, drove the enemy from his frontiers. On 26th May 1863 he captured Herat, but on 9th June he died suddenly in the midst of victory, after playing a great rôle in the history of Central Asia for forty years. He named as his successor his son, Shir Ali Khan. (E. I. C.)

**Dostoievsky, Feodor Mikhailovitch** (1821–1881), Russian author, born at Moscow, 30th October 1821, was the second son of a retired military surgeon of a decayed noble family. He was educated at Moscow and at the military engineering academy at St Petersburg, which he left in 1843 with the grade of sub-lieutenant. Next year his father died, and he resigned his commission in order to devote himself to literature—thus commencing a long struggle with ill-health and penury. In addition to the old Russian masters Gogol and Pushkin, Balzac and George Sand supplied him with literary ideals. He knew little of Dickens, but his first story is thoroughly Dickensian in character. The hero is a Russian "Tom Pinch," who entertains a pathetic, humble adoration for a fair young girl, a solitary waif like himself. Characteristically, the Russian story ends in "tender gloom." The girl marries a middle-aged man of property; the hero dies of a broken heart, and his funeral is described in lamentable detail. The germ of all Dostoievsky's imaginative work may be discovered here. The story was submitted in manuscript to the Russian critic, Bielinski, and excited his astonishment by its power over the emotions. It appeared in the course of 1846 in the *Recueil de Saint-Petersbourg*, under the title of "Poor People." An English version, *Poor Folk*, with an introduction by Mr George Moore, appeared in 1894. The successful author became a regular contributor of short tales to the *Annals of the Country*, a monthly periodical conducted by Kraevsky; but he was wretchedly paid, and his work, though revealing extraordinary power and intensity, commonly lacks both finish and proportion. Poverty and physical suffering robbed him of the joy of life and filled him with bitter thoughts and morbid imaginings. During 1847 he became an enthusiastic member of the revolutionary reunions of the political agitator, Petrachevski. Many of the students and younger members did little more than discuss the theories of Fourier and other economists at these gatherings. Exaggerated reports were eventually carried to the police, and on 23rd April 1849 Dostoievsky and his brother, with thirty other suspected personages, were arrested. After a short examination by the secret police they were lodged in the fortress of St Peter and St Paul at St Petersburg, in which confinement Feodor wrote his story *A Little Hero*. On 22nd December 1849 the accused were all condemned to death and conveyed in vans to a large scaffold in the Simonovsky Place. As the soldiers were preparing to carry out the sentence, the prisoners were informed that their penalty was commuted to exile in Siberia. The novelist's sentence was four years in Siberia and enforced military service in the ranks for life. On Christmas Eve 1849 he commenced the long journey to Omsk, and remained in Siberia, "like a man buried alive, nailed down in his coffin," for four terrible years. His Siberian experiences are graphically narrated in a volume to which he gave the name of *Recollections of a Dead-House* (1858). It was known in an English translation as *Buried Alive in Siberia* (1881; another version, 1888). His release only subjected him to fresh indignities as a common soldier at Semipalatnisk; but in 1858, through the intercession of an old school-fellow, General Todleben, he was made an under-officer; and in 1859, upon the accession of Alexander II., he was finally recalled from exile. In 1858 he had married a widow, Madame Isaieff, but she died at St Petersburg in 1867 after a somewhat stormy married life.

After herding for years with the worst criminals,

Dostoievsky obtained an exceptional insight into the dark and seamy side of Russian life. He formed new conceptions of human life, of the balance of good and evil in man, and of the Russian character. Psychological studies have seldom, if ever, found a more intense form of expression than that embodied by Dostoievsky in his novel called *Crime and Punishment.* The hero Raskolnikoff is a poor student, who is led on to commit a murder partly by self-conceit, partly by the contemplation of the abject misery around him. Unsurpassed in poignancy in the whole of modern literature is the sensation of compassion evoked by the scene between the self-tormented Raskolnikoff and the humble street-walker, Sonia, whom he loves, and from whom, having confessed his crime, he derives the idea of expiation. Raskolnikoff finally gives himself up to the police and is exiled to Siberia, whither Sonia follows him. The book gave currency to a number of ideas, not in any sense new, but specially characteristic of Dostoievsky: the theory, for instance, that in every life, however fallen and degraded, there are ecstatic moments of self-devotion; the doctrine of purification by suffering, and by suffering alone; and the ideal of a Russian people forming a social state at some future period bound together by no obligation save mutual love and the magic of kindness. In this visionary prospect, as well as in his objection to the use of physical force, Dostoievsky anticipated in a remarkable manner some of the conspicuous tenets of his great successor Tolstoi. The book electrified the reading public in Russia upon its appearance in 1866, and its fame was confirmed when it appeared in Paris in 1867. To his remarkable faculty of awakening reverberations of melancholy and compassion, as shown in his early work, Dostoievsky had added, by the admission of all, a rare mastery over the emotions of terror and pity. But such mastery was not long to remain unimpaired. *Crime and Punishment* was written when he was at the zenith of his power. His remaining works exhibit frequently a marvellous tragic and analytic power, but they are unequal, and deficient in measure and in balance. The chief of them are: *The Injured and the Insulted, The Demons* (1867), *The Idiot* (1869), *The Adult* (1875), *The Brothers Karamzov* (1881).

From 1865, when he settled in St Petersburg, Dostoievsky was absorbed in a succession of journalistic enterprises, in the Slavophil interest, and suffered severe pecuniary losses. He had to leave Russia, in order to escape his creditors, and to seek refuge in Germany and Italy. He was further harassed by troubles with his wife, and his work was interrupted by epileptic fits and other physical ailments. It was under such conditions as these that his most enduring works were created. He managed finally to return to Russia early in the 'seventies, and was for some time director of the *Russian World.* From 1876 he published a kind of review, entitled *Carnet d'un Ecrivain,* to the pages of which he committed many strange autobiographical facts and reflections. The last eight years of his life were spent in comparative prosperity at St Petersburg, where he died on 9th February 1881.

His life had been irremediably seared by his Siberian experiences. He looked prematurely old; his face bore an expression of accumulated sorrow; in disposition he had become distrustful, taciturn, contemptuous—his favourite theme the superiority of the Russian peasant over every other class; as an artist, though uncultured, he had ever been subtle and sympathetic, but latterly he was tortured by tragic visions and morbidly preoccupied by exceptional and perverted types. M. de Vogüé, in his admirable *Ecrivains Russes,* has worked out with some success a parallel between the later years of Dostoievsky and those of Jean Jacques Rousseau. Siberia effectually convinced the novelist of the impotence of Nihilism in such a country as Russia; but though he was assailed by ardent Liberals for the reactionary trend of his later writings, Dostoievsky became, towards the end of his life, an extremely popular figure, and his funeral, on 12th February 1881, was the occasion of one of the most remarkable demonstrations of public feeling ever witnessed in the Russian capital. The death of the Russian novelist was not mentioned in the London press; it is only since 1885, when *Crime and Punishment* first appeared in English, that his name has become at all familiar in England, mainly through French translations. A complete edition of his novels was issued at St Petersburg in fourteen volumes, 1882–83. Two critical studies by Tchij and Zelinsky appeared at Moscow in 1885, and a German life by Hoffmann at Vienna in 1899. (T. SE.)

**Douai,** chief town of arrondissement, department of Nord, France, 20 miles south of Lille, junction on railway from Paris to Lille. The manufacture of glass, oil, sugar, and paper, wool-spinning, leather-currying, and bell-founding, have all become important industries. The town library now contains 80,000 volumes and 1800 manuscripts.—Dorignies, 1½ mile north of the town, is an important industrial suburb; Sin-le-Noble, Dechy, and Sambres, though distinct municipalities, are practically suburban. The port traffic of Douai and Dorignies in 1898 amounted to 427,677 tons. Population (1881), 20,608; (1901), 33,918.

**Doubs,** a department in the east of France, bordering on Switzerland. It is traversed by the Jura mountains and watered by the Doubs.

Area, 2052 square miles. The population decreased from 310,963 in 1886 to 296,957 in 1901. Births in 1899, 7222, of which 590 were illegitimate; deaths, 6706; marriages, 2186. There were in 1896 1024 schools, with 51,000 pupils; 1 per cent. of the population was illiterate. The area under cultivation in 1896 comprised 1,097,186 acres, of which only 360,785 acres were arable and 12,355 acres in vines. Forest, on the other hand, covers an extensive area, occupying with the natural grass lands nearly 741,000 acres. The wheat crop yielded in 1899 a value of only £420,000, but the produce of the green crop and grass lands amounted in 1899 to the value of £902,000, the natural pastures alone yielding the value of £603,000. The live-stock in 1899 included 19,990 horses, 121,330 cattle, 47,750 sheep, 45,580 pigs, and 6700 goats. Doubs has no coal, but it turned out, in 1896, 6200 metric tons of iron and 20,000 tons of rock-salt. It produced, in 1898, 19,000 metric tons of wrought-iron and steel, of the value of £170,000. Among the other industries watch-making takes the first rank, having its centres at Besançon and Montbéliard, while distillation holds the second place, producing a yearly average of 687,800 gallons. Besançon, the capital, has 55,250 inhabitants.

**Douglas,** a town and railway station on the east coast of the Isle of Man, England, 75 miles by steamer north-west of Liverpool. The steamship communication with this popular watering-place has been greatly improved during the last twenty-five years, in particular the service connecting it with Liverpool, Barrow, Fleetwood, Dublin, and the Clyde. Many improvements have also been made in the town itself, which has displaced Castletown as the legal capital of the island. A magnificent parade sweeps around the bay; new wide streets have been cleared in the old town and constructed in the new; municipal buildings, a free library, a second theatre, and three music-halls with capacious dancing saloons have been erected; an electric tramway has been laid down to all parts of the island; cable and horse trams encircle the town; and a sporting summer golf course has been constructed at Howstrake, in addition to the winter course behind the town. Many of the public undertakings, such as the water-works, abattoirs, markets, and cemetery, are under municipal control. Douglas is in the parish of Onchan, and in 1881 had a population of 15,725; in

1901, 19,126, with a suburban population just outside the borough of 3100.

**Douglass, Frederick** (1817–1895), American orator, was born in Tuckahoe, Talbot county, Md., and died in Anacostia, D.C., 20th February 1895. His mother was a slave and his father a white man. He learned to read and write, and was allowed to hire his own time and work in a shipyard. In 1838 he escaped from slavery, and soon settled in New Bedford, Mass. A speech made by him in 1841 resulted in his being offered the agency of the Massachusetts Anti-Slavery Society. From that time his oratorical powers rapidly developed, and he aroused much interest in the cause of emancipation. In 1845 he made a lecturing tour through the British Isles, where he remained until 1847. For many years after 1847 he conducted an anti-slavery weekly journal at Rochester, N.Y. He encouraged, but did not actually participate in, John Brown's invasion of Harper's Ferry. In 1870 he became editor of the *New National Era* in Washington, D.C. When, in 1871, President Grant appointed a commission to report on the question of annexing Santo Domingo to the United States, Douglass became its assistant-secretary. In 1872 he was presidential elector at large for the State of New York. From 1876 to 1881 he was marshal of the District of Columbia, after which time he was its recorder of deeds for five years. From 1889 to 1891 he was United States minister to Hayti. The experiences of his life were described in an autobiography.

**Doukhobors, The.**—"Doukhobors" is a name given by the Russian Orthodox clergy to a community of nonconformist peasants. The word etymologically signifies "spirit-fighters," being originally intended by the priesthood to convey that they fight against the Spirit of God; but the Doukhobors themselves accepted the term as signifying that they fight, not against, but for and with the Spirit. Of late, however, they have decided to give up this name and call themselves "Christians of the Universal Brotherhood." This religious community was first heard of in the middle of the 18th century. By the end of that century or the beginning of the 19th their doctrine had become so clearly defined, and the number of their members had so greatly increased, that the Russian Government and Church, considering this sect to be peculiarly obnoxious, started an energetic campaign against it. The foundation of the Doukhobors' teaching consists in the belief that the Spirit of God is present in the soul of man, and directs him by its word within him. They understand the coming of Christ in the flesh, his works, teaching, and sufferings, in a spiritual sense. The object of the sufferings of Christ, in their view, was to give an example of suffering for truth. Christ continues to suffer in us even now when we do not live in accordance with the behests and spirit of his teaching. The whole teaching of the Doukhobors is penetrated with the Gospel spirit of love. Worshipping God in the spirit, they affirm that the outward Church and all that is performed in it and concerns it has no importance for them. The Church is where two or three are gathered together, *i.e.*, united in the name of Christ. They pray inwardly at all times; on fixed days they assemble for prayer-meetings, at which they greet each other fraternally with low bows, thereby acknowledging every man as a bearer of the Divine Spirit. Their teaching is founded on tradition, which is called among them the "Book of Life," because it lives in their memory and hearts. It consists of sacred songs or chants, partly composed independently, partly formed out of the contents of the Bible, which, however, has evidently been gathered by them orally, as until quite lately they were almost entirely illiterate and did not possess any written book. They found alike their mutual relations and their relations to other people—and not only to people, but to all living creatures—exclusively on love, and therefore they hold all people equal and brethren. They extend this idea of equality also to the Government authorities, obedience to whom they do not consider binding upon them in those cases when the demands of these authorities are in conflict with their conscience; while in all that does not infringe what they regard as the will of God they willingly fulfil the desire of the authorities. They consider killing, violence, and in general all relations to living beings not based on love as opposed to their conscience and to the will of God. They are industrious and abstemious in their lives, and when living up to the standard of their faith they present one of the nearest approaches to the realization of the Christian ideal which has ever been attained.

Such, in their most general character, are the beliefs for which the Doukhobors have long endured cruel persecution. Under Nicholas I., in the years 1840 and 1850, the Doukhobors, who on religious grounds refused to participate in military service, were all banished from the government of Tauris—whither they had been previously transported from various parts of Russia by Alexander I.—to Transcaucasia, near the Turkish frontier. But neither the severe climate nor the neighbourhood of wild and warlike hillmen shook their faith, and in the course of half a century, in one of the most unhealthy and unfertile localities in the Caucasus, they transformed this wilderness into flourishing colonies, and continued to live a Christian and laborious life, making friends instead of fighting with the hillmen. But the wealth to which they attained in the Caucasus weakened for a time their moral fervour, and little by little they began to depart somewhat from the requirements of their belief. As soon, however, as events happened among them which disturbed their outward tranquillity, the religious spirit which had guided their fathers immediately revived within them. In 1887, in the reign of the Tsar Alexander III., universal military service was introduced in the Caucasus; and even those for whom, as in the case of the Doukhobors, it had formerly been replaced with banishment, were called upon to serve. This measure took the Doukhobors unawares, and at first they outwardly submitted to it. About the same time, by the decision of certain Government officials, the right to the possession of the public property of the Doukhobors (valued at about £50,000) passed from the community to one of their members, who had formed out of the more demoralized Doukhobors a group of his own personal adherents, which was henceforth called the "Small Party." Soon afterwards several of the most respected representatives of the community were banished to the government of Archangel. This series of calamities was accepted by the Doukhobors as a punishment from God, and a spiritual awakening of a most energetic character ensued. The majority (about 12,000 in number) resolved to revive in practice the traditions left them by their fathers, which they had departed from during the period of opulence. They again renounced tobacco, wine, meat, and every kind of excess, many of them dividing up all their property in order to supply the needs of those who were in want, and they collected a new public fund. They also renounced all participation in acts of violence, and therefore refused military service. In confirmation of their sincerity, in the summer of 1895 the Doukhobors of the "Great Party," as they were called in distinction from the "Small Party," burnt all the arms which they, like other inhabitants of the Caucasus, had taken up for their protection from wild animals, and those who were in

the army refused to continue service. At the commencement of the reign of the Tsar Nicholas II., in 1895, the Doukhobors became the victims of a series of persecutions, Cossack soldiers plundering, insulting, beating, and maltreating both men and women in every way. More than four hundred families of Doukhobors who were living in the province of Tiflis were ruined and banished to Georgian villages. Of 4000 thus exiled, more than 1000 died in the course of the first two years from exhaustion and disease; and more would have perished had not information reached Count Leo Tolstoy and his friends, and through them the Society of Friends in England. Funds were immediately raised by sympathizers for alleviating the sufferings of the starving victims. At the same time an appeal, written by Tolstoy and some of his friends, requesting the help of public opinion in favour of the oppressed Doukhobors, was circulated in St Petersburg and sent to the Emperor and higher Government officials. The Doukhobors themselves asked for permission to leave Russia, and the Society of Friends petitioned the Emperor to the same effect. In March 1898 the desired permission was granted, and the first party of Doukhobors, 1126 in number, were able in the summer of 1898 to sail from Batum for Cyprus, which was originally chosen for their settlement because at that time funds were not sufficient for transferring them to any other British territory. But as contributions accumulated, it was found possible to send a number of Doukhobor emigrants to Canada, whither they arrived in two parties, numbering above 4000, in January 1899. They were joined in the spring of the same year by the Cyprus party, and another party of about 2000 arrived from the Caucasus. In all about 7500 Doukhobor immigrants arrived in Canada. The Canadian Government did their best to facilitate the immigration, and allotted land to the Doukhobors in the provinces of Assiniboia near Yorkton and of Saskatchewan near Thunder Hill and Prince Albert. They were very cordially received by the population of the Canadian port towns. In April 1901, in the Canadian House of Commons, the Minister of Justice made a statement about them in which he said that "not a single offence had been committed by the Doukhobors; they were law-abiding, and if good conduct was a recommendation, they were good immigrants. . . . The large tracts of land demanded population, and if they were not given to crime, the conclusion was that they would make good citizens." About eighteen months after they arrived in Canada the Doukhobors sent the Society of Friends a collective letter in which they sincerely thanked the English and American Friends for all the generous help of every kind they had received at their hands, but begged the Quakers to cease sending them any more pecuniary support, as they were now able to stand on their own feet, and therefore felt it right that any further help should be directed to others who were more in need of it.

**Doulton, Sir Henry** (1820–1897), English inventor and manufacturer of pottery, born in Vauxhall 25th July 1820, was from the age of fifteen actively employed in the pottery works of his father, John Doulton, at Lambeth. One of the first results of his many experiments was the production of good enamel glazes. In 1846 he initiated in Lambeth the pipe works, in which he superintended the manufacture of the drainage and sanitary appliances which have helped to make the firm of Doulton famous. In 1870 the manufacture of "Art pottery" was begun at Lambeth, and in 1877 works were opened at Burslem, where almost every variety of china and porcelain, as well as artistic earthenware, has been produced. Works have since been opened at Rowley Regis, Smethwick, St Helens, Paisley, and Paris. After the Paris Exhibition of 1878, Henry Doulton was made a Chevalier of the Legion of Honour. In 1872 the "Art department" was instituted in the Doulton works, giving employment to both male and female artists, amongst whom such workers as George Tinworth and the Misses Barlow have obtained a reputation outside their immediate sphere. In 1887 Mr Doulton received the honour of knighthood, and a few years later was awarded the Albert Medal by the Society of Arts. He married in 1849 the daughter of Mr J. L. Kennaby; she died in 1888. Sir Henry Doulton took an active interest, as Almoner, in St Thomas's Hospital. He died in London 18th November 1897. (R. F. S.)

**Douro** (in Spanish, *Duero*; Portuguese, *Douro*), a river of the Iberian peninsula. It rises in the Sierra d'Urbion (between the Sierra de la Demanda and the Sierra de Moncayo), describes a wide curve eastwards past Soria, then flows on the whole west right across the Spanish tableland, passing on the way Valladolid and Zamora; then from Paradela to Barca d'Alva it flows south-west and forms the frontier between Spain and Portugal. It crosses Portugal in an east to west direction in a narrow and tortuous bed, and enters the Atlantic 3 miles below Oporto. In Spain it receives from the right the rivers Pisuerga, Valderaduey, and Esla, and from the left several small streams which drain the Sierra Guadarrama; and in Portugal the Agueda, Côa, and Paiva from the left, and the Sabor, Túa, and Tamega from the right. The lower stream is beset with numerous rapids, called *pontos*, and is subject to swift and violent inundations. On this account navigation is attended with difficulties and risks between its mouth and Barca d'Alva; but a railway, running for the most part along the right bank, traverses the Portuguese portion of the river. The mouth of the river is partly blocked by a rocky bar, but has recently been improved. Its total length is about 420 miles, of which 140 are in Portugal. Its waters abound in fish, especially trout, shad, and lampreys.

**Douro,** a former province of Portugal, corresponding to the present districts of Oporto, Aveiro, and Coimbra (*qq.vv.*). Area, 3506 square miles. Population (1900), 1,237,374, giving 353 inhabitants to the square mile.

**Douwes-Dekker, Edward.** See DEKKER, EDWARD DOUWES.

**Dover,** the principal Cinque Port, municipal and parliamentary borough of Kent, England, terminal station of the South-Eastern and Chatham and Dover Railway, 76 miles by rail east-south-east of London. The municipal borough, till 1895 coextensive with the parliamentary, was then extended to include parts of parishes previously in the rural district of Dover. In 1885 the parliamentary representation was reduced to one member. In 1888 the gates of Wellington dock were widened 10 feet to admit the new Channel steamers; new coal stores were erected on the Northampton quay; the shipway was lengthened 40 feet, and widened for the reception of vessels up to 800 tons. In 1891 it was resolved to construct a new commercial harbour, estimated to cost about £700,000 and to be finished by the end of 1901. Begun in 1893, the works include (1) an open iron viaduct, 1260 feet long, joining the east pier; (2) the extension of the east pier, of solid masonry, to a length of 1920 feet; (3) two jetties, 1100 and 500 feet long respectively; (4) reclamation of 5 acres of land, between the Admiralty pier and the mouth of the present harbour, as a water station; (5) an extension of the Admiralty pier. The harbour thus formed will have a

water area of 75 acres, with a depth within the mouth of over 40 feet at low water. A great national harbour, estimated to occupy ten years in building and to cost £3,500,000, commenced in 1899, will comprise (1) an extension of the Admiralty pier east-south-east for a distance of 2000 feet, over 90 feet from base of wall to top of parapet; (2) an east arm, projecting 3300 feet into the sea; (3) a sea-wall, 3850 feet long, from the Castle jetty to the base of the east arm; (4) reclamation of the foreshore between the back of the wall and the base of the cliff; (5) a breakwater 4300 feet long, $\frac{3}{4}$ mile from the shore, from the south extremity of the east arm, south-west and west by south to a point 800 feet from the Admiralty pier extension, with entrance at each end of about 7 fathoms at low water. The Admiralty harbour will cover at low water an area of 610 acres, accommodating twenty of the largest ships and any number of armed cruisers, torpedo and dispatch boats, at any time needing its shelter. Coaling berths will extend 1800 feet along the inner side of the east arm. To strengthen its defences, the construction of three powerful forts was begun in 1899. Three pits have been sunk to work the coal discovered by boring. The water-works, which are the property of the corporation, are situated on Castle Hill, and have given a constant supply since 1870. The rainfall at this point, 200 feet above sea-level, was 24·34 inches in 1899 and 31·34 inches in 1900. The sewage outfall, constructed in 1885 at a cost of £7500, discharges into the sea, to the west of the Admiralty pier, at a distance of 1225 feet from the shore. There is a promenade pier (1893), costing £24,000; electric lighting, begun in 1894; electric tramways, with a length of $3\frac{1}{4}$ miles; and a public park (1883), of $22\frac{1}{2}$ acres. Besides the mail and packet service, Dover does a trade in shipbuilding, timber, rope and sail making, and ships' stores. Shipping at port in 1888, 46 vessels of 3478 tons; in 1898, 66 of 5066 tons. Entered in 1888, 2923 vessels of 720,337 tons; cleared, 2895 of 716,544 tons. Entered in 1898, 3718 vessels of 1,015,609 tons; cleared, 3675 of 1,006,951 tons. Imports of foreign and colonial merchandise in 1888, valued £6,333,468; exports of produce of the United Kingdom, £1,128,104. In 1898, imports valued £9,451,780; exports, £1,564,225. Area of parliamentary borough, 1317 acres. Population (1881), 30,270; (1901), 33,300. Area of municipal borough as now extended, $1779\frac{1}{2}$ acres. Population (1891), 33,503; (1901), 41,782.

**Dover,** capital of the state and of Kent county, Delaware, U.S.A., on the Philadelphia, Wilmington, and Baltimore Railroad, at an altitude of 40 feet. It is the site of the state college for coloured students, opened in 1892. Population (1880), 2811; (1890), 3061; (1900), 3329, of whom 123 were foreign-born and 772 negroes.

**Dover,** capital of Strafford county, New Hampshire, U.S.A., in 43° 14′ N. lat. and 70° 54′ W. long., on Cocheco river, 12 miles from its mouth, at the lower falls, and at the head of navigation. Its street plan is irregular, few of the streets are paved, and its water supply, derived from Cocheco river, is obtained by gravity. It is at the intersection of two branches of the Boston and Maine Railway, and these, with the river, give it considerable commerce. Its manufactures consist mainly of cotton and woollen goods. Population (1880), 11,687; (1890), 12,790; (1900), 13,207, of whom 3298 were foreign-born.

**Dover,** a town of Morris county, New Jersey, U.S.A., on the Rockaway river, at an altitude of 570 feet. It is on the Morris Canal, and on the Central of New Jersey and the Delaware, Lackawanna, and Western Railways. It contains iron furnaces, rolling mills, and steel works. Population (1880), 2958; (1900), 5938, of whom 947 were foreign-born and 53 negroes.

**Dower,** or the life interest of the widow in a third part of her husband's lands, is governed in the United Kingdom, so far as women married after 1st January 1834 are concerned, by the Dower Act, 1834, and under it only attaches on the husband's death to the lands which he actually possessed for an estate of inheritance at the time of his death. The wife is now entitled to dower out of equitable estates, but joint estates are still exempt. By the Act the wife's dower is placed completely under her husband's control. It does not attach to any land actually disposed of by him in his lifetime or by his will, nor to any land from which he has declared by deed his wife shall not be entitled to dower. He may also defeat her right, either as to any particular land or to all his lands, by a declaration in his will; while it is subject to all the deceased husband's debts and contracts, and to any partial estates which he may have created during his life or by his will. A widow tenant in dower may make leases for twenty-one years under the Settled Estates Act, 1878. Free-bench is an analogous right in regard to copyhold land; it does not fall within the Dower Act, 1834, and varies with the custom of each manor. At common law, and prior to the Act of 1834, dower was of a very different nature. The wife's right attached, while the husband was still living, to any land whereof he was solely seised in possession (excluding equitable and joint estates) for an estate of inheritance at any time during the continuance of the marriage, provided that any child the wife might have had could have been heir to the same, even though no child was actually born. When once this right had attached, it adhered to the lands, notwithstanding any sale or devise the husband might make; nor was it liable for his debts. In this way dower proved an obstacle to the free alienation of land, for it was necessary for a husband wishing to make a valid conveyance to obtain the consent of his wife releasing her right to dower. This release was only effected by a fine, the wife being separately examined. Often, by reason of the expense involved, the wife's concurrence was not obtained, and thus the title of the purchaser was defective during the wife's lifetime. The acceptance of a jointure by the wife before marriage was, however, destructive of dower; if after marriage, she was put to her election between it and dower. By the ingenuity of the old conveyancers, devices, known as "uses to bar dower" (the effect of which was that the purchaser never had at any time an estate of inheritance in possession), were found to prevent dower attaching to newly purchased lands, and so to enable the owner to give a clear title, without the need of the wife's concurrence, in the event of his wishing, in his turn, to convey the land. All this has, however, been swept away by the Dower Act, 1834, and a purchaser of land need not now trouble himself to inquire whether the dower of the wife of the vendor has been barred, or to insist on her concurrence in a fine. (H. S. S.)

**Down,** a maritime county of Ireland, province of Ulster, bounded on the N. by Belfast Lough and Antrim, on the E. and S. by the Irish Sea, and on the W. by Armagh. The area of the judicial county in 1900 was 612,093 acres, of which 255,745 were tillage, 262,237 pasture, 763 fallow, 13,573 plantation, 1688 turf bog, 4129 marsh, 41,495 barren mountain, and 32,463 water, roads, fences, &c. The new administrative county under the Local Government (Ireland) Act, 1898, includes the portion of the town of Newry formerly situated in Armagh, but does not include the portion of Lisburn and the portion of Belfast formerly situated in Down. The population in 1881 was 272,107; in 1891, 267,059, of whom 126,268 were males and 140,791 females, divided

as follows among the different religions:—Presbyterians, 106,346; Roman Catholics, 73,410; Protestant Episcopalians, 65,239; Methodists, 7742; and other denominations, 14,322. The population in 1901 was 289,335 (Roman Catholics, 76,535; Protestant Episcopalians, 71,568; Presbyterians, 114,182; Methodists, 10,543; others, 16,507), being an increase of 7·3 per cent.; but these figures include part of the county borough of Belfast.

The following table gives the number of births, deaths, and marriages in various years:—

| Year. | Births. | Deaths. | Marriages. |
|---|---|---|---|
| 1881 | 5671 | 4257 | 1062 |
| 1891 | 7005 | 5419 | 1376 |
| 1899 | 7752 | 5366 | 1464 |

The chief towns in the county are Newtownards, Banbridge, Downpatrick, and Holywood.

*Education.*—The following table gives the degree of education in 1891:—

| | Males. | Females. | Total. | Percentage. | | |
|---|---|---|---|---|---|---|
| | | | | R. C. | Pr.Ep. | Presb. |
| Read and write . | 72,239 | 77,570 | 149,809 | 62·6 | 73·4 | 82·3 |
| Read only . . | 10,750 | 17,442 | 28,192 | 15·8 | 16·0 | 12·1 |
| Illiterate . . | 10,650 | 12,487 | 23,137 | 21·6 | 10 6 | 5·6 |

The percentage of illiterates among Roman Catholics in 1881 was 26·5. In 1891 there were 15 superior schools with 621 pupils (Roman Catholics 191 and Protestants 430), and 460 primary schools with 32,461 pupils (Roman Catholics 8690 and Protestants 23,771). The number of pupils on the rolls of the national schools on 30th September 1899 was 50,220, of whom 11,595 were Roman Catholics and 38,625 Protestants.

*Administration.*—The county is divided into four parliamentary divisions, north, south, east, west, the number of registered electors in 1900 being respectively 9886, 8944, 8489, and 8815. The borough of Newry returns one member. The ratable value in 1900 was £794,836. By the Local Government (Ireland) Act 1898, the fiscal and administrative duties of the grand jury and (to a less extent) of other bodies were transferred to a county council, urban and rural district councils were established, and under that Act the county now comprises 7 urban and 8 rural sanitary districts.

*Agriculture.*—The following tables show the acreage under crops, including meadow and clover, and the amount of live-stock in 1881, 1891, 1895, and 1900. The figures for 1900 are for the new administrative county.

| Year. | Wheat. | Oats. | Barley, Beans, &c. | Potatoes. | Turnips. | Other Green Crops. | Flax. | Meadow and Clover. | Total. |
|---|---|---|---|---|---|---|---|---|---|
| 1881 | 22,365 | 106,094 | 1715 | 51,668 | 16,813 | 4754 | 28,089 | 70,035 | 301,533 |
| 1891 | 13,277 | 101,060 | 967 | 48,305 | 17,957 | 4666 | 12,968 | 73,367 | 272,567 |
| 1895 | 7,225 | 100,090 | 851 | 46,053 | 20,017 | 3835 | 16,634 | 78,957 | 273,662 |
| 1900 | 9,531 | 95,218 | 1372 | 43,014 | 20,101 | 4114 | 7,738 | 74,395 | 255,745 |

For 1899 the total value of the cereal and other crops was estimated by the Registrar-General at £1,755,140. The number of acres under pasture in 1881 was 217,543; in 1891, 242,700, and in 1900, 262,237.

| Year. | Horses and Mules. | Asses. | Cattle. | Sheep. | Pigs. | Goats. | Poultry. |
|---|---|---|---|---|---|---|---|
| 1881 | 31,465 | 1382 | 129,447 | 56,745 | 34,272 | 10,911 | 636,802 |
| 1891 | 32,171 | 1302 | 150,481 | 101,931 | 51,703 | 13,791 | 719,682 |
| 1895 | 35,142 | 1359 | 151,261 | 92,791 | 45,651 | 12,838 | 822,123 |
| 1900 | 33,700 | 1454 | 159,745 | 122,166 | 42,153 | 11,186 | 1,049,373 |

The number of milch cows in 1891 was 53,743, and in 1900 54,087. It is estimated that the total value of cattle, sheep, and pigs in 1899 was £2,242,131. In 1900 the number of holdings not exceeding 1 acre was 6306, between 1 and 5, 3775, between 5 and 15, 8904, between 15 and 30, 6505, between 30 and 50, 3181, between 50 and 100, 1756, between 100 and 200, 333, between 200 and 500, 87, and above 500, 23—total, 30,870. The number of loans issued (the number of loans being the same as the number of tenants) under the Land Purchase Acts, 1885, 1891, and 1896, up to 31st March 1900, was 1314, amounting to £497,045. The number of loans sanctioned for agricultural improvements under sect. 31 of the Land Act, 1881, between 1882 and 1900 was 102, and the amount issued £8887. The total amount issued on loan for all classes of works under the Land Improvement Acts from the commencement of operations to 31st March 1900 was £99,765.

*Fisheries.*—In 1899, 375 vessels, employing 1120 hands, were registered in the deep sea and coast fishery districts of Donaghadee, Strangford, and Newcastle. In the same year 15,519 cwt. of herring were caught in the Ardglass fisheries. (W. H. Po.)

**Downpatrick,** a market-town and county town of Down, Ireland, on Strangford Lough, 18 miles south-east of Belfast by rail. It ceased to be a parliamentary borough in 1885. It is governed by town commissioners, but under the powers conferred by the Local Government (Ireland) Act, 1898, can apply to be constituted an urban sanitary district. The County Down Railway connects the town with Belfast and (among other places) with Newtownards and Newcastle, a favourite watering-place. In 1883 an assembly hall was erected at the expense of Lord Dunleath, and a new lunatic asylum has been opened near the town. Population (1881), 3901; (1901), 2992.

**Doyle, Sir Francis Hastings Charles,** Bart. (1810–1888), English man of letters, was born at Nunappleton, Yorkshire, 22nd August 1810, and was educated at Eton and Oxford, where he took a first-class in classics in 1831, and became a Fellow of All Souls'. He read for the Bar, but was chiefly interested in literature and society. Among his intimate friends was Mr Gladstone, whose "best man" he was; but in later life their political opinions widely differed. In 1841 he published *Miscellaneous Verses*, (1844) *Two Destinies*, (1852) *The Duke's Funeral*, (1866) *Return of the Guards and other Poems*; and from 1867 to 1877 he was professor of poetry at Oxford. In 1869 some of the lectures he delivered were published in book form. In 1886 he published his *Reminiscences*, full of records of the interesting people he had known. Sir Francis Doyle succeeded his father (chairman of the Board of Excise) as second baronet in 1839, and married in 1844. From 1846 he held various important offices in the Customs. He died 8th June 1888. A cultivated and agreeable man and writer, Doyle's poetry is memorable for certain isolated and spirited pieces, which became popular because of their thoroughly English celebration of manly deeds. The best known are his ballads on the "Birkenhead" disaster and on "The Private of the Buffs."

**Doyle, Richard** (1824–1883), English artist, son of John Doyle, the caricaturist known as "H. B." (1797–1868), was born in London in 1824. His father's "Political Sketches" took the town by storm in the days of Lord Grey and Lord Melbourne. The son was an extremely precocious artist, and in his "Home for the Holidays," done when he was twelve, and his "Comic English Histories," drawn four years later, he showed extraordinary gifts of humour and fancy. He had no art training outside his father's studio. In 1843 he joined the staff of *Punch*, drawing cartoons and a vast number of illustrations, but he retired in 1850, in consequence of the attitude adopted by that paper towards what was known as "the papal aggression," and especially towards the pope himself. In 1854 he published his "Continental Tour of Brown, Jones, and Robinson." His illustrations to three of the *Christmas Books* of Charles Dickens, and to *The Newcomes* by Thackeray, are reckoned among his principal achievements; and his fanciful pictures of elves and fairies have always been general favourites. He died on 11th December 1883. His most popular drawing is his cover of *Punch*.

**Dozy, Reinhart Pieter Anne** (1820–1883), Dutch Arabic scholar of French (Huguenot) origin, was born at Leyden in February 1820. The Dozys, like so

many other contemporary French families, emigrated to the Low Countries after the revocation of the Edict of Nantes, but some of the former appear to have settled in Holland as early as 1647. Dozy studied at the University of Leyden, obtained the degree of doctor in 1844, was appointed an extraordinary professor of history in 1850, and professor in 1857. The first results of his extensive studies in Oriental literature, Arabic language and history, manifested themselves in 1847, when he published Al-Marrakushi's *History of the Almohades* (Leyden, 2nd ed., 1881), which, together with his *Scriptorum Arabum loci de Abbaditis* (Leyden, 1846–63, 3 vols.), his editions of Ibn-Adhari's *History of Africa and Spain* (Leyden, 1848–52, 3 vols.), of Ibn-Badrun's *Historical Commentary on the Poem of Ibn-Abdun* (Leyden, 1848), and his *Dictionnaire detaillé des noms des vêtements chez les Arabes* (Amsterdam, 1845)—a work crowned by the Dutch Institute—stamped Dozy as one of the most learned and critical Arabic scholars of his day. But his real fame as a historian mainly rests on his great work *Histoire des Mussulmans d'Espagne, jusqu'à la Conquête de l'Andalousie par les Almoravides*, 711–1110 (Leyden, 1861; 2nd ed., *ibid.*, 1881; a graphically written account of Moorish dominion in Spain, which shed new light on many obscure points, and has remained the standard work on the subject. Dozy's *Recherches sur l'Histoire et la Littérature de l'Espagne pendant le Moyen Age* (Leyden, 2 vols., 1849; 2nd and 3rd ed., completely recast, 1860 and 1881) form a needful and wonderfully trenchant supplement to his *Histoire des Mussulmans*, in which he mercilessly exposes the many tricks and falsehoods of the monks in their chronicles, and effectively demolishes a good part of the Cid legends. As an Arabic scholar Dozy stands well-nigh unsurpassed in his *Supplément aux Dictionnaires Arabes* (Leyden, 1877–81, 2 vols.), a work full of research and learning, a storehouse of Arabic lore. To the same class belongs his *Glossaire des mots espagnols et portugais, dérivés de l'Arabe*, edited with Dr W. H. Engelmann of Leipzig (Leyden, 1866; 2nd ed., 1868), and a similar list of Dutch words derived from the Arabic. Dozy also edited Al Makkari's *Analectes sur l'Histoire et la Littérature des Arabes d'Espagne* (Leyden, 1855–61, 2 vols.), and, in conjunction with his friend and worthy successor, Professor De Goeje, at Leyden, Edrisi's *Description de l'Afrique et de l'Espagne* (1866), also the *Calendrier de Cordoue de l'année* 961; *texte arabe et ancienne traduction latine* (Leyden, 1874). *Het Islamisme* (*Islamism;* Haarlem, 1863; 2nd ed., 1880; French translation) is a popular exposition of Mahommedanism, of a more controversial character; and *De Israelieten te Mekka* (*The Israelites at Mecca*, Haarlem, 1864, became the subject of a rather heated discussion in Jewish circles. Dozy died at Leyden, May 1883. (H. Ti.)

**Drachmann, Holger** (1846–——), Danish poet and dramatist, the son of a well-known physician of Copenhagen, Dr A. G. Drachmann, whose family was of German extraction, was born in Copenhagen on the 9th October 1846. Owing to the early death of his mother, who was a Dane, the child was left much to his own devices. He soon developed a fondness for semi-poetical performances, and loved to organize among his companions heroic games, in which he himself took such parts as those of Tordenskjold and Niels Juul. His studies were belated, and he did not enter the university until 1865, leaving it in 1866 to become a student in the Academy of Fine Arts. From 1866 to 1870 he was learning, under Professor Sörensen, to become a marine painter, and not without success. But about the latter date he came under the influence of Georg Brandes, and, without abandoning art, he began to give himself more and more to literary ideas. He travelled very extensively in England, Scotland, France, Spain, and Italy, and his literary career began by his sending letters about his journeys to the Danish newspapers. After returning home, he settled for some time in the island of Bornholm, painting seascapes. He now issued his earliest volume of *Poems*, 1872, and joined the group of young Radical writers who gathered under the banner of Brandes. Drachmann was unsettled, and still doubted whether his real strength lay in the pencil or in the pen. By this time he had enjoyed a surprising experience of life, especially among sailors, fishermen, students, and artists, and the issues of the Franco-German War and the French Commune had persuaded him that a new and glorious era was at hand. His volume of lyrics, *Muffled Melodies*, 1875, proved that Drachmann was a poet with a real vocation, and he began to produce books in prose and verse with great rapidity. *Young Blood*, 1876, is his solitary attempt at a realistic novel of to-day. But in 1877 he returned to his true field in his magnificent *Songs of the Sea*, and he won the passionate admiration of his countrymen by his prose work, with interludes in verse, called *Over the Frontier There*, a series of impressions made on Drachmann by a visit to the scenes of the war with Germany. During the succeeding years he was a great traveller, visiting most of the principal countries of the world, but particularly familiarizing himself, by protracted voyages, with the sea and with the life of man in maritime places. In 1879 he published *Tendrils and Roses*, amatory lyrics of a very high order of melody, in which he showed a great advance in technical art. To the same period belongs *On the Faith and Honour of a Sailor*, a volume of short stories in prose. It was about this time that Drachmann broke with Brandes and the Radicals, and set himself at the head of a sort of "Nationalist" or popular-Conservative party in Denmark. He continued to celebrate the life of the fishermen and sailors in books, whether in prose or verse, which were the most popular of their day. *Paul and Virginia* and *Lars Kruse* (both 1879); *East of the Sun and Moon*, 1880; *Chrysalis and Butterfly*, 1882; and *Strandby Folk*, 1883, were among these. In 1882 Drachmann published his fine translation, or paraphrase, of Byron's *Don Juan*. He now gave his attention to dramatic composition, and in 1885 his romantic play called *Once upon a Time* enjoyed an enormous success on the boards of the Royal Theatre, Copenhagen. He pursued this profitable course, and his tragedies of *Völund Smed* and *Brav-Karl* have made him the most popular playwright of Denmark. He published a volume of exquisitely fantastic *Melodramas* in rhymed verse, a collection which contains some of Drachmann's most perfect work. It is impossible to give the titles of all the poet's publications, which are extremely numerous. In 1899 he enjoyed a great success through Scandinavia by his romantic play called *Gurre*, and in 1900 he brought out a prose story called *Dædalus* and a brilliant lyrical drama, *Hallfred Vandraadeskjald*. In the winter of 1900 Drachmann visited England, and was entertained at dinner by fifty English authors. A man of lofty stature and commanding appearance, he looks like a poet and a Viking. He is unquestionably the greatest writer that Denmark produced in the last quarter of the 19th century.

**Dragasani**, a town in Rumania, of 4398 inhabitants, on the right bank of the river Olt. It was the scene in 1821 of a bloody battle between the Turks and the troops of Ypsilanti, in which the latter were completely defeated. The vines of the neighbouring hills produce the best white wines in the country.

**Drama.**—The last quarter of the 19th century witnessed a very distinct progress in the theatrical life of the world at large. It is at present too early to unify this movement by tracing it to any one cause or set of causes, political, economic, or psychological. Yet the fact is clear that the new theatrical literature of England, France, Germany, and even of Italy and America, represents a break with tradition rather than a continuance of it.

*English drama.*

In England the whole mechanism of theatrical life had undergone a radical change in the middle decades of the century. At the root of this change lay the immense growth of population and the enormously increased facilities of communication between London and the provinces. Similar causes came into operation, of course, in France, Germany, and Austria, but were much less distinctly felt, because the numerous and important subventioned theatres of these countries remained more or less unaffected by economic influences. Free trade in theatricals (subject only to certain licensing regulations and to a court censorship of new plays) was established in England by an Act of 1843, which abolished the long moribund monopoly of the "legitimate drama" claimed by the "Patent Theatres" of Drury Lane and Covent Garden. The drama was thus formally subjected to the operation of the law of supply and demand, like any other article of commerce, and managers were left, unaided and unhampered by any subvention or privilege, to cater to the tastes of a huge and growing community. Theatres very soon multiplied, competition grew ever keener, and the long run, with its accompaniments of ostentatious decoration and lavish advertisement, became the one object of managerial effort. This process of evolution may be said to have begun in the second quarter of the 19th century and completed itself in the 3rd. The system which obtains to-day, almost unforeseen in 1825, was in full operation in 1875. The repertory theatre, with its constant changes of programme, maintained on the Continent partly by subventions, partly by the mere force of artistic tradition, had become in England a faint and far-off memory. There was not a single theatre in London at which plays, old and new, were not selected and mounted solely with a view to their continuous performance for as many nights as possible, anything short of fifty nights constituting an ignominious and probably ruinous failure. It was found, too, that those theatres were most successful which were devoted exclusively to exploiting the talent of an individual actor. Thus when the fourth quarter of the century opened the long "run" and the actor-manager were in firm possession of the field.

The outlook was in many ways far from encouraging. It was not quite so black, indeed, as it had been in the late 'fifties and early 'sixties, when the "legitimate" enterprises of Phelps at Sadler's Wells and Charles Kean at the Princess's had failed to hold their ground, and when modern comedy and drama were represented almost exclusively by adaptations from the French. There had been a slight stirring of originality in the series of comedies produced by T. W. Robertson (1829–1871) at the Prince of Wales's Theatre, Tottenham Street, where, under the management of Mr and Mrs Bancroft,[1] a new school of mounting and acting, minutely faithful (in theory at any rate) to everyday reality, had come into existence. But the hopes of a revival of English comedy seemed to have died with Robertson's death. One of his followers, James Albery (1832–1889), possessed both imagination and wit, but had not the strength of character to do justice to his talent, and sank into a mere adaptor. In the plays of another disciple, H. J. Byron (1836–1884), the Robertsonian or "cup-and-saucer" school declined upon sheer inanity. Of the numerous plays signed by Tom Taylor (1817–1880) some were original in substance, but all were cast in the machine-made French mould. Wilkie Collins (1824–1889), in dramatizing some of his novels, produced somewhat crude anticipations of the modern "problem play." The literary talent of Mr W. S. Gilbert (*b.* 1836) displayed itself in a group of comedies both in verse and prose; but Mr Gilbert saw life from too peculiar an angle to represent it otherwise than fantastically. The Robertsonian impulse seemed to have died utterly away, leaving behind it only five or six very insubstantial comedies and a subdued, unrhetorical method in acting. This method the Bancrofts proceeded to apply, during the 'seventies, to revivals of stage classics, such as *The School for Scandal*, *Money*, and *Masks and Faces*, and to adaptations from the French of Sardou.

While the modern drama appeared to have relapsed into a comatose condition, poetic and romantic drama was giving some signs of life. At the Lyceum in 1871 Henry Irving (*b.* 1838) had leapt into fame by means of his performance of Mathias in *The Bells*, an adaptation from the French of Erckmann-Chatrian. He followed this up by an admirably picturesque performance of *Charles I.* in a play of that name by W. G. Wills (1828–1893), a writer of some talent, which ran to waste for lack of an adequate sense of either dramatic or literary form. In the autumn of 1874 the great success of Mr Irving's Hamlet was hailed as the prelude to a revival of tragic acting. As a matter of fact, it was the prelude to a long series of remarkable achievements in romantic drama and melodrama. Mr Irving's lack of physical and vocal resources prevented him from scaling the heights of tragedy, and his Othello, Macbeth, and Lear could not be ranked among his successes; but he was admirable in such parts as Richard III., Shylock, Iago, and Wolsey, while in melodramatic parts, such as Louis XI. and the hero and villain of *The Lyons Mail*, he was unsurpassed. Mephistopheles in a version of *Faust* (1885), perhaps the greatest popular success of his career, added nothing to his reputation for artistic intelligence; but on the other hand his Becket in Tennyson's play of that name (1893) was one of his most masterly efforts. His management of the Lyceum (1878–1899) did so much to raise the status of the actor and to restore the prestige of poetic drama, that the knighthood conferred upon him in 1895 was felt to be no more than an appropriate recognition of his services. But unfortunately his managerial career had scarcely any significance for the living English drama. He seldom experimented with a new play, and, of the few which he did produce, only *The Cup* and *Becket* by Lord Tennyson have the remotest chance of being remembered.

To trace the history of the English drama, then, we must go back to the Prince of Wales's Theatre. Even while it seemed that French comedy of the school of Scribe was resuming its baneful predominance, the seeds of a new order of things were slowly germinating. *Diplomacy*, an adaptation of Sardou's *Dora*, produced in 1878, brought together on the Prince of Wales's stage Mr and Mrs Bancroft, Mr and Mrs. Kendal, Mr John Clayton, and Mr Arthur Cecil—in other words, the future managers of the Haymarket, the St James's, and the Court Theatres, which were destined to see the first real stirrings of a literary revival. Mr and Mrs Kendal, who, in conjunction with Mr John Hare, managed the St James's Theatre

[1] Sir Squire Bancroft, who was knighted in 1897, was born on 14th May 1841, and made his début at Birmingham in 1861. In 1865 he joined the company with which Miss Marie Wilton (whom he afterwards married) opened the Prince of Wales's Theatre, in Tottenham Court Road, London; and he became co-manager with his wife in 1868. They moved to the Haymarket in 1880, and formally retired from the stage in 1885, but at rare intervals afterwards occasionally reappeared.

from 1879 to 1888, produced Mr A. W. Pinero's first play of any consequence, *The Money-Spinner* (1881), and afterwards *The Squire* (1882) and *The Hobby Horse* (1887). Mr and Mrs Bancroft, who, after entirely rebuilding the Haymarket Theatre, managed it from 1880 till their retirement in 1885, produced in 1883 Mr Pinero's *Lords and Commons;* and Messrs Clayton and Cecil produced at the Court Theatre between 1885 and 1887 his three brilliant farces *The Magistrate*, *The Schoolmistress*, and *Dandy Dick*, which, with the sentimental comedy, *Sweet Lavender*, produced at Terry's Theatre in 1888, assured his position as an original and fertile dramatic humorist of no small literary power. It is to be noted, however, that Mr Pinero was almost the only original playwright represented under the Bancroft, Hare-Kendal, and Clayton-Cecil managements, which relied for the rest upon adaptations and revivals. Adaptations of French vaudevilles were the staple productions of Mr Charles Wyndham's management at the Criterion from its beginning in 1876 until 1893, when he first produced an original play of any importance. When Mr Beerbohm Tree went into management at the Haymarket in 1887, he still relied largely on plays of foreign origin. Mr George Alexander's first managerial ventures (Avenue Theatre, 1890) were two adaptations from the French. Until well on in the 'eighties, indeed, adaptation from the French was held the normal occupation of the British playwright, and original composition a mere episode. Robertson, Byron, Albery, Gilbert, Tom Taylor, Charles Reade, Herman Merivale, G. W. Godfrey, all produced numerous adaptations; Mr Sydney Grundy was for twenty years occupied almost exclusively in this class of work; Mr Pinero himself has adapted more than one French play. To this day the managers have not quite unlearnt the habit of regarding Paris as the natural fountainhead of English drama. The 'eighties, then, may on the whole be regarded as showing a very gradual decline in the predominance of France on the English stage, and an equally slow revival of originality, so far as comedy and drama were concerned, manifesting itself mainly in the plays of Mr Pinero.

The reaction against French influence, however, was no less apparent in the domain of melodrama and operetta than in that of comedy and drama. Until well on in the 'seventies, D'Ennery and his disciples, adapted and imitated by Boucicault and others, ruled the melodramatic stage. The reaction asserted itself in two quarters—in the East End at the Grecian Theatre, and in the West End at the Princess's. In *The World*, produced at Drury Lane in 1880, Paul Meritt (*d.* 1895) and Henry Pettitt (*d.* 1893) brought to the West End the "Grecian" type of popular drama; and at Drury Lane it has survived in the elaborately spectacular form imparted to it by Sir Augustus Harris, who managed that theatre from 1879 till his death in 1896. The production of Mr G. R. Sims's *Lights o' London* at the Princess's in 1881, under Mr Wilson Barrett's management, also marked a new departure; and the two streams of melodrama flowed together in a long series of popular plays at the Adelphi Theatre, from about 1882 to almost the end of the century. The "Adelphi" as opposed to the "Drury Lane" type of drama has recently died out in the West End, apparently because a host of suburban theatres drew away its audiences. Of all these English melodramas, only one, *The Silver King*, by Mr H. A. Jones (Princess's, 1882) could for a moment compare in invention or technical skill with the French dramas they supplanted. The fact remains, however, that even on this lowest level of dramatic art the current of the time set decisively towards home-made pictures of English life, however crude and puerile.

For twenty-five years, from 1865 to 1890, the English stage was overrun with French operettas of the school of Offenbach. Hastily adapted by slovenly hacks, their librettos (often witty in the original) became incredible farragos of metreless doggrel and punning ineptitude. The great majority of them are now so utterly forgotten that one scarcely realizes, until one looks into the records, how in their heyday they swarmed on every hand. The reaction began in 1875 with the performance at the Royalty Theatre of *Trial by Jury*, by Mr W. S. Gilbert and Mr (afterwards Sir) Arthur Sullivan (1842–1900). This was the prelude to that brilliant series of witty and melodious extravaganzas which began with *The Sorcerer* at the Opera Comique Theatre in 1877, but has been mainly associated with the Savoy Theatre, opened by Mr D'Oyly Carte (*d.* 1901) in 1881. Little by little the Gilbert and Sullivan operettas (of which the most famous, perhaps, were *H.M.S. Pinafore*, 1878, *Patience*, 1881, and *The Mikado*, 1885) undermined the popularity of the French opera-bouffes, and at the same time that of the indigenous "burlesques" which, graceful enough in the hands of their inventor J. R. Planché (1796–1880), had become mere incoherent jumbles of buffoonery, devoid alike of dramatic ingenuity and of literary form. When, early in the 'nineties, the collaboration between Mr Gilbert and Sir Arthur Sullivan became intermittent, and the vogue of the Savoy somewhat declined, a new class of extravaganza arose, under the designation of "musical comedy" or "musical farce." It first took form in a piece called *In Town*, by Messrs "Adrian Ross" and Osmond Carr (Prince of Wales's Theatre, 1892), and rapidly became very popular. In these plays the scene and costumes are almost always modern, though sometimes exotic, and the prose dialogue, setting forth an attenuated and entirely negligible plot, is frequently interrupted by musical numbers. The lyrics are often very clever pieces of rhyming, totally different from the inane doggrel of the old opera-bouffes and burlesques. In other respects there is little to be said for the literary or intellectual quality of "musical farce"; but being an entirely English (or Anglo-American) product, it falls into line with the other indications we have noted of the general decline—one might almost say extinction—of French influence on the English stage.

To what causes are we to trace this gradual disuse of adaptation? In the domain of modern comedy and drama, to two causes acting simultaneously: the decline in France of the method of Scribe, which produced "well-made," exportable plays, more or less suited to any climate and environment; and the rise in England of a generation of playwrights more original, thoughtful, and able than their predecessors. It is not at all to be taken for granted that the falling off in the supply of exportable plays meant a decline in the absolute merit of French drama. That point is discussed in the section *French Drama* below. The historian of the future may very possibly regard the movement in France, no less than the movement in England, as a step in advance, and may even see in the two movements co-ordinate manifestations of one tendency. Be this as it may, the fact is certain that as the playwrights of the Second Empire gradually died off and were succeeded by the authors of the "new comedy," plays which would bear transplantation became ever fewer and farther between. It is worthy of note that (a few mere buffooneries apart) most of the adaptations produced since 1890 have been from comedies and novels of a very much older date—works of Labiche and of Dumas *père* and *fils*. Attempts to acclimatize the poetical drama of the present generation—*Pour la Couronne*, *Le Chemineau*, *Cyrano de Bergerac*—have all been more or less unsuccessful.

Having noted the decline of adaptation, we may now trace a stage farther the development of the English drama. The first stage, already surveyed, ends with the production of *Sweet Lavender* in 1888. Up to this point its author, Mr Pinero (*b.* 1855), stood practically alone, and had won his chief successes as a humorist. Mr Henry Arthur Jones (*b.* 1851) was known as little more than an able melodramatist, though in one play, *Saints and Sinners* (1884), he had made some attempt at a serious study of provincial life. Mr R. C. Carton (*b.* 1856) had written, in collaboration, one or two plays of slight account. Mr Sydney Grundy (*b.* 1848) had produced scarcely any original work. None of the other dramatists of to-day had as yet appeared on the horizon. The second stage may be taken as extending from 1889 to 1893. On 24th April 1889 Mr John Hare opened the new Garrick Theatre with *The Profligate*, by Mr Pinero—an unripe and superficial piece of work in many ways, but still a great advance, both in ambition and achievement, upon any original work the stage had seen for many a year. With all its faults, this play notably enlarged at one stroke the domain open to the English dramatist. And it did not stand alone. The same year saw the production of two plays by Mr Jones, *Wealth* and *The Middleman*, in which a distinct effort towards a serious criticism of life was observable, and of two plays by Mr Grundy, *A Fool's Paradise* and *A White Lie*, which, though very French in method, were at least original in substance. Mr Jones during the next two years made a steady advance with *Judah* (1890), his first really mature production, and *The Dancing Girl* and *The Crusaders* (1891), in the latter of which he made his first attempt to work the vein of social satire. Mr Pinero in these years was putting forth less than his whole strength in *The Cabinet Minister* (1890), *Lady Bountiful* and *The Times* (1891), and *The Amazons* (March 1893). But meanwhile new talents were coming forward. The management of Mr George Alexander, which opened at the Avenue Theatre in 1890, but was transferred in the following year to the St James's, brought prominently to the front Mr Carton, Mr Haddon Chambers, and Mr Oscar Wilde. Mr Carton's two sentimental comedies, *Sunlight and Shadow* (1890) and *Liberty Hall* (1892), showed excellent literary workmanship, but did not yet reveal his true originality as a humorist. Mr Haddon Chambers's work (notably *The Idler*, 1891) was as yet sufficiently commonplace; but in *Lady Windermere's Fan* (1892) Mr Oscar Wilde showed himself at his first attempt a brilliant and accomplished dramatist. Mr Wilde's subsequent plays, *A Woman of No Importance* (1893) and *An Ideal Husband* and *The Importance of being Earnest* (1895), though marred by mannerism and insincerity, did much to promote the movement we are here tracing, and his painful downfall gave it a distinct, though temporary, check.

As the production of *The Profligate* marked the opening of the second period in the revival of English drama, so the production of the same author's *The Second Mrs Tanqueray* is very clearly the starting-point of the third period—of the phase of development still in progress. Before attempting to trace its course, however, we may do well to glance at certain conditions which probably influenced it.

In the first place, economic conditions. The Bancroft-Robertson movement at the old Prince of Wales's, between 1865 and 1870, was of even more importance from an economic than from a literary point of view. By making their little theatre a luxurious place of resort, and faithfully imitating in their productions the accent, costume, and furniture of upper and upper-middle class life, the Bancrofts had initiated a reconciliation between Society and the Stage. Throughout the middle decades of the century it was the constant complaint of the managers that the world of wealth and fashion was by no means to be tempted to the theatre. The Bancroft management changed all that. It was at the Prince of Wales's that half-guinea stalls were first introduced; and these stalls were always filled. As other theatres adopted the same policy of upholstery, both on and off the stage, fashion extended its complaisance to them as well. In yet another way the reconciliation was promoted—by the ever-increasing tendency of young men and women of good birth and education to seek a career upon the stage. For the past fifteen years, then, the theatre has been one of the favourite amusements of fashionable (though not necessarily of intellectual) Society. It is often contended that the influence of the sensual and cynical stall audience is a pernicious one. In some ways, no doubt, it is detrimental; but there is another side to the case. Even the cynicism of Society marks an intellectual advance upon the sheer rusticity which prevailed during the middle years of the 19th century and accepted without a murmur plays (original and adapted) which bore no sort of relation to life. In a celebrated essay published in 1879, Matthew Arnold dwelt on the sufficiently obvious fact that the result of giving English names and costumes to French characters was to make their sayings and doings utterly unreal and "fantastic." During the years of French ascendancy, audiences had quite forgotten that it was possible for the stage to be other than "fantastic" in this sense. They no longer thought of comparing the mimic world with the real world, but were content with what may be called abstract humour and pathos, often of the crudest quality. The cultivation of external realism, coinciding with, and in part occasioning, the return of Society to the playhouse, gradually led to a demand for some approach to plausibility in character and action as well as in costume and decoration. The stage ceased to be entirely "fantastic," and began to essay, however imperfectly, the representation, the criticism of life. It cannot be denied that the influence of Society tends to narrow the outlook of English dramatists and to trivialize their tone of thought. But this is, in all likelihood, a passing phase of development; and cleverly trivial representations of reality are, after all, to be preferred to brainless concoctions of sheer emptiness.

Quite as important, from the economic point of view, as the reconciliation of Society to the stage, was the reorganization of the mechanism of theatrical life in the provinces which took place between 1865 and 1875. From the Restoration to the middle of the 19th century the system of "stock companies" had been universal. Every great town in the three kingdoms had its established theatre with a resident company, playing the "legitimate" repertory, and competing, often by illegitimate means, for the possession of new London successes. The smaller towns, and even villages, were grouped into local "circuits," each served by one manager with his troupe of strollers. The "circuits" supplied actors to the resident stock companies, and the stock companies served as nurseries to the patent theatres in London. Metropolitan "stars" travelled from one country theatre to another, generally alone, sometimes with one or two subordinates in their train, and were "supported," as the phrase went, by the stock company of each theatre. Under this system, scenery, costumes, and appointments were often grotesquely inadequate, and performances almost always rough and unfinished. On the other hand, the constant practice in a great number and variety of characters afforded valuable training for actors, and developed many remarkable talents.

As a source of revenue to authors, the provinces were practically negligible. Stageright was unprotected by law; and even if it had been protected, it is doubtful whether authors could have got any considerable fees out of country managers, whose precarious ventures usually left them a small enough margin of profit.

The spread of railways throughout the country gradually put an end to this system. The "circuits" disappeared early in the 'fifties, the stock companies survived until about the middle of the 'seventies. As soon as it was found easy to transport whole companies, and even great quantities of scenery, from theatre to theatre throughout the length and breadth of Great Britain, it became apparent that the rough makeshifts of the stock company system were doomed. Here again we can trace to the old Prince of Wales's Theatre the first distinct impulse towards the new order of things. Robertson's comedies not only encouraged but absolutely required a style of art, in mounting, stage-management, and acting, not to be found in the country theatres. To entrust them to the stock companies was well-nigh impossible. On the other hand, to quote Sir Squire Bancroft, "perhaps no play was ever better suited than *Caste* to a travelling company; the parts being few, the scenery and dresses quite simple, and consequently the expenses very much reduced." In 1867, then, a company was organized and rehearsed in London to carry round the provincial theatres as exact a reproduction as possible of the London performance of *Caste* and Robertson's other comedies. The smoothness of the representation, the delicacy of the interplay among the characters, were new to provincial audiences, and the success was remarkable. About the same time the whole Haymarket company, under Buckstone's management, began to make frequent rounds of the country theatres; and other "touring combinations" were soon organized. It is manifest that the "combination" system and the stock company system cannot long coexist, for a manager cannot afford to keep a stock company idle while a London combination is occupying his theatre. The stock companies, therefore, soon dwindled away, and were probably quite extinct before the end of the 'seventies. Under the present system, no sooner is a play an established success in London than it is reproduced in one, two, or three exact copies and sent round the provincial theatres (and the numerous suburban theatres which have sprung up since 1895), Company A serving first-class towns, Company B the second-class towns, and so forth. The process is very like that of taking plaster casts of a statue, and the provincial companies often stand to their London originals very much in the relation of plaster to marble. Even the London scenery is faithfully reproduced in material of extra strength, to stand the wear-and-tear of constant removal. The result is that, instead of the square pegs in round holes of the old stock company system, provincial audiences now see pegs carefully adjusted to the particular holes they occupy, and often incapable of fitting any other. Instead of the rough performances of old, they are now accustomed to performances of a mechanical and soulless smoothness. In some ways the gain is undeniable, in other ways the loss is great. The provinces are no longer, in any effective sense, a nursery of fresh talents for the London theatres, for the art acquired in touring combinations is that of mimicry rather than of acting. Moreover, provincial playgoers have lost all personal interest and pride in their local theatres, which have no longer any individuality of their own, but serve as a mere frame for the presentation of a series of ready-made London pictures. Christmas pantomime is the only theatrical product that has any local flavour in it, and even it is very often only a second-hand London production, touched up with a few topical allusions. Again, the railways which bring London productions to the country take country playgoers by the thousand to London. The wealthier classes, in the Lancashire, Yorkshire, and Midland towns at any rate, do almost all their theatre-going in London, or during the autumn months when the leading London companies go on tour. Thus the better class of comedy and drama has a hard fight to maintain itself in the provinces, and the companies devoted to melodrama and musical farce enjoy an ominous preponderance of popularity.

On the whole, however—and this is the main point to be observed with regard to the literary development of the drama—the economic movement of the five-and-twenty years between 1865 and 1890 was enormously to the advantage of the dramatic author. A London success meant a long series of full houses at high prices, on which he took a handsome percentage. The provinces, in which a popular playwright would often have three or four plays going the rounds simultaneously, became a steady source of income. And, finally, it was found possible, even before international copyright came into force, to protect stageright in the United States, so that about the beginning of the 'eighties large receipts began to pour in from America. Thus successful dramatists, instead of living from hand to mouth, like their predecessors of the previous generation, found themselves in comfortable and even opulent circumstances. They had leisure for reading, thought, and careful composition, and they could afford to gratify their ambition with an occasional artistic experiment. Failure might mean a momentary loss of prestige, but it would not spell ruin. A distinctly progressive spirit, then, began to animate the leading English dramatists—a spirit which found intelligent sympathy in such managers as Mr John Hare, Mr George Alexander, Mr Beerbohm Tree, and finally Mr Charles Wyndham. Nor must it be forgotten that, though the laws of literary property, internal and international, are still far from perfect, it has been found possible during the past ten years to print and publish plays without incurring loss of stageright either at home or in America. The playwrights of the present generation have accordingly a motive for giving literary form and polish to their work which was quite inoperative with their predecessors, whose productions were either kept jealously in manuscript or printed only in miserable and totally unreadable stage editions. It is no small stimulus to ambition to know that even if a play prove to be in advance of the public to which it is originally presented, it will not perish utterly, but will, if it have any inherent vitality, continue to live as literature.

**Influence of foreign drama.**

Having now summed up the economic conditions which made for progress, let us glance at certain intellectual influences which tended in the same direction. The establishment of the Théâtre Libre in Paris, towards the close of 1887, unquestionably marked the beginning of a period of restless experiment throughout the theatrical world of Europe. M. Antoine and his supporters were in open rebellion against the artificial methods of Scribe and the Second Empire playwrights. Their effort was to transfer to the stage the realism, the so-called "naturalism," which had been dominant in French fiction since 1870 or earlier; and this naturalism was doubtless, in its turn, the outcome of the scientific movement of the century. New methods (or ideals) of observation, and new views as to the history and destiny of the race, could not fail to produce a profound effect upon art; and though the modern theatre is a cumbrous contrivance, slow to adjust its orientation to the winds of the spirit, even it at last began to revolve, like a rusty windmill, so as to fill its sails in the main current of the intellectual atmosphere.

Under the section *French Drama* (below), the history of the Théâtre Libre is outlined. Within three or four years of its inception M. Antoine's experiment had been imitated in Germany, England, and America. The Freie Bühne of Berlin came into existence in 1889, the Independent Theatre of London in 1891. Similar enterprises were set on foot in Munich and other cities. In America several less formal experiments of a like nature were attempted, chiefly in Boston and New York. Nor must it be forgotten that in Paris itself the Théâtre Libre did not stand alone. Many other *théâtres à côté* sprang up, under such titles as "Théâtre d'Art," "Théâtre Moderne," "Théâtre de l'Avenir Dramatique." The most important and least ephemeral was the "Théâtre de l'Œuvre," founded in 1893 by M. Lugné-Poë, which represented mainly, though not exclusively, the symbolist reaction against naturalism.

The impulse which led to the establishment of the Théâtre Libre was, in the first instance, entirely French. If any foreign influence helped to shape its course, it was that of the great Russian novelists. Tolstoi's *Puissance des Ténèbres* was the only "exotic" play announced in M. Antoine's opening manifesto. But the whole movement, in France and elsewhere, was soon to receive a potent stimulus from a somewhat unlikely quarter. Born in 1828, the Norwegian poet Henrik Ibsen was already an old man before his fame became European. His youth and middle life had been devoted to romantic tragedy and satiric drama in verse. Not till 1877 did he finally restrict himself to prose and to the modern world. In the series of plays which then followed he anticipated the process of evolution which was to lead, both in France and Germany, through prosaic realism to an intensely imaginative treatment of everyday life, touched here and there with symbolism. As a matter of fact, the author of *Brand* and *Peer Gynt* was above all things a poet. In essaying a literal and photographic transcript of reality, he was merely, as it were, trying a new set of tools. He is least himself in his most prosaic play, *Pillars of Society*. In its successors the poet gradually but decisively reasserts himself, and shakes off the trammels of the theoretic realist. Still, there was a sufficient element of realism, narrowly so called, in *A Doll's House*, *Ghosts*, *An Enemy of the People*, and *The Wild Duck* to awaken the enthusiasm of the realist party, just as the symbolists afterwards hailed with delight *The Lady from the Sea*, *The Master Builder*, and *Little Eyolf*.

Ibsen's early romantic plays had been known in Germany since 1875. In 1878 *Pillars of Society*, and in 1880 *A Doll's House*, achieved wide popularity, and held the German stage side by side with *A Bankruptcy*, by Björnstjerne Björnson (*b.* 1832). But these plays had little influence on the German drama. Their methods were, indeed, not essentially different from those of the French school of the Second Empire, which were then dominant in Germany as well as everywhere else. It was *Ghosts* (acted in Augsburg and Meiningen 1886, in Berlin 1887) that gave the impulse which, coalescing with the kindred impulse from the French Théâtre Libre, was destined in the course of a few years to create a new dramatic literature in Germany. During the middle decades of the century Germany had produced some dramatists of solid and even remarkable talent, such as Friedrich Hebbel (1813–1865), Heinrich Laube (1806–1884), Karl Gutzkow (1811–1878), and Gustav Freytag (1816–1895). Even the generation which held the stage after 1870, Paul Heyse (*b.* 1830), Paul Lindau (*b.* 1839), and Adolf Wilbrandt (*b.* 1837), with numerous writers of light comedy and farce, such as Wichert, Blumenthal, Von Moser, L'Arronge, and Schönthan, had produced a good many works of some merit. But, in the main, French artificiality and frivolity predominated on the German stage. In point of native talent and originality, the Austrian popular playwright Ludwig Anzengruber (1839–1889) was probably well ahead of his North German contemporaries. It was in 1889, with the establishment of the Berlin Freie Buhne, that the reaction definitely set in. In Berlin, as afterwards in London, *Ghosts* was the first play produced on the outpost stage, but it was followed in Berlin by a very rapid development of native talent. Less than a month after the performance of Ibsen's play, Gerhart Hauptmann (*b.* 1862) came to the front with *Vor Sonnenaufgang*, an immature piece of almost unrelieved Zolaism, which he soon followed up, however, with much more important works. In *Das Friedensfest* (1890) and *Einsame Menschen* (1891) he had transferred his allegiance from Zola to Ibsen. His true originality first manifested itself in *Die Weber* (1892); and since that time he has produced nine or ten plays in several different styles, but all bearing the stamp of a potent individuality. His most popular productions have been the dramatic poems *Hannele* and *Die Versunkene Glocke*, the low-life comedy *Der Biberpelz*, and the low-life tragedy *Fuhrmann Henschel*. Other remarkable playwrights belonging to the Freie Bühne group are Max Halbe (*b.* 1865), author of *Jugend* and *Mutter Erde*, and Otto Erich Hartleben (*b.* 1864), author of *Hanna Jagert* and *Rosenmontag*. These young men, however, so quickly gained the ear of the general public, that the need for a special "free stage" was no longer felt, and the Freie Bühne, having done its work, ceased to exist. Unlike the French Théâtre Libre and the English Independent Theatre, it had been supported from the outset by the most influential critics, and had won the day almost without a battle. The productions of the new school soon made their way even into some of the subventioned theatres; but it was the unsubventioned Deutsches Theater of Berlin that most vigorously continued the tradition of the Freie Bühne. One or two playwrights of the new generation, however, did not actually belong to the Freie Buhne group. Hermann Sudermann (*b.* 1857) produced his first play, *Die Ehre*, in 1888, the year before the Freie Bühne came into existence, and his most famous work, *Heimat*, in 1892. In him the influence of Ibsen is very clearly perceptible; while Arthur Schnitzler of Vienna, author of *Liebelei*, may rather be said to derive his inspiration from the Parisian "new comedy."

The promoters of the Théâtre Libre had probably never heard of Ibsen when they established that institution, but three years later his fame had reached France, and *Les Revenants* was produced by the Théâtre Libre, 29th May 1890. Within the next two or three years almost all his modern plays were acted in Paris, most of them either by the Théâtre Libre or by L'Œuvre. Close upon the heels of the Ibsen influence followed another, less potent, but by no means negligible. The exquisite tragic symbolism of Maurice Maeterlinck (*b.* 1862) began to find numerous admirers about 1890. In 1891 his one-act play *L'Intruse* was acted; in 1893, *Pelléas et Mélisande*. By this time, too, the reverberation of the impulse which the Théâtre Libre had given to the Freie Bühne began to be felt in France. In 1893 Hauptmann's *Die Weber* was acted in Paris, and, being frequently repeated, made a deep and lasting impression.

The English Théâtre Libre, the Independent Theatre, opened its first season, 13th March 1891, with a performance of *Ghosts*. This was not, however, the first introduction of Ibsen to the English stage. On 7th June 1889 (six weeks after the production of *The Profligate*), *A Doll's House* was acted at the Novelty Theatre, and ran for three

weeks, amid a storm of critical controversy. In the same year *Pillars of Society* was presented in London. In 1891 and 1892 *A Doll's House* was frequently acted; *Rosmersholm* was produced in 1891, and again in 1893; in May and June 1891 *Hedda Gabler* had a run of several weeks; and early in 1893 *The Master Builder* enjoyed a similar passing vogue. During these years, then, Ibsen was very much "in the air" in England, as well as in France and Germany. The Independent Theatre, in the meantime, under the management of Mr J. T. Grein, found but scanty material to deal with. It presented translations of Zola's *Thérèse Raquin*, and of *A Visit*, by the Danish dramatist Edward Brandes; but it brought to the front only one English author of any note, in the person of Mr George Bernard Shaw (*b.* 1856), whose "didactic realistic play," *Widowers' Houses*, it produced in December 1892. In France and Germany the Free Theatres were like artesian wells, tapping rich subterranean reservoirs which only awaited an outlet. In England it must be owned that the most industrious boring (ominous word!) produced only a meagre trickle. It appeared that all the available talent was already at the surface.

None the less is it true that the ferment of fresh energy, which between 1887 and 1893 had created a new dramatic literature both in France and in Germany, was distinctly felt in England as well. England did not take at all kindly to it. Rumours (some of them too well founded) of the excesses of cynical crudity perpetrated in the French *théâtres à côté* established a very general prejudice against the whole movement. Nor did the productions of Ibsen's plays tend to soothe the alarmed susceptibilities of the critics and the public. They were received with an outcry of horror and reprobation, the echoes of which have not yet died away. A great part of this clamour was due to sheer misunderstanding, but some of it, no doubt, arose from genuine and deep-seated distaste, which even perfect comprehension would have left unaltered. As for the dramatists of recognized standing, they one and all, both from policy and from conviction, adopted a hostile attitude towards Ibsen, expressing at most a theoretical respect overborne by practical dislike. To represent that they imitated him would be to misrepresent them grossly. Consciously and voluntarily they did nothing of the sort. Yet his influence permeated the atmosphere. He had revealed possibilities of technical stagecraft and psychological delineation that, once realized, were not to be banished from the mind of the thoughtful playwright. They haunted him in spite of himself. Still subtler was the influence exerted over the critics and the more intelligent public. Deeply and genuinely as many of them disliked Ibsen's works, they found, when they returned to the old-fashioned play, the adapted frivolity or the home-grown sentimentalism, that this they disliked still more. On every side, then, there was an instinctive or deliberate reaching forward towards something new; and once again it was Mr Pinero who ventured the decisive step.

On 27th May 1893 *The Second Mrs Tanqueray* was produced at the St James's Theatre. This is not the place for a detailed criticism of the play, or an attempt to forecast its ultimate status in English literature. Whether it will be acted fifty years hence is a question which the future may safely be left to answer. What here concerns us is the historical fact—questioned only by critics who have been denied a sense of proportion—that with *The Second Mrs Tanqueray* the English acted drama ceased to be a merely insular product, and took rank in the literature of Europe. Here was a play which, whatever its faults, was obviously comparable with the plays of Dumas, of Sudermann, of Björnson, of Echegaray. It might be better than some of these plays, worse than others; but it stood on the same artistic level. The fact that such a play could not only be produced, but could brilliantly succeed, on the London stage gave a potent stimulus to progress. It encouraged ambition in authors, enterprise in managers. What *Hernani* was to the romantic movement of the 'thirties, and *La Dame aux Camélias* to the realistic movement of the 'fifties, *The Second Mrs Tanqueray* has been to the movement of the 'nineties towards the serious stage-portraiture of English social life. All the forces which we have been tracing—Robertsonian realism of externals, the leisure for thought and experiment involved in vastly improved financial conditions, the substitution in France of a simpler, subtler technique for the outworn artifices of the Scribe school, and the electric thrill communicated to the whole theatrical life of Europe by contact with the genius of Ibsen—all these slowly converging forces coalesced to produce, in *The Second Mrs Tanqueray*, an epoch-marking play.

Even the critics, few but insistent, who deny all merit to *The Second Mrs Tanqueray*, cannot fail to be struck by what, on their theory, must seem an extraordinary coincidence: the fact that the English plays produced since 1893 have been, on an average, incomparably better than those produced before that date. Mr Pinero himself has given us five plays—*The Notorious Mrs Ebbsmith*, *The Benefit of the Doubt*, *The Princess and the Butterfly*, *Trelawny of the "Wells,"* and *The Gay Lord Quex*—any one of which it would be absurd to compare with the very best of his earlier productions. Though more unequal in workmanship than *The Second Mrs Tanqueray*, they all show a marked advance even upon that play in originality of conception and intellectual force. In January 1893 Mr Charles Wyndham initiated a new policy at the Criterion Theatre, and produced an original play, *The Bauble-Shop*, by Mr Henry Arthur Jones. Though not quite without merit, it belonged very distinctly to the pre-Tanqueray order of things; whereas in *The Case of Rebellious Susan*, produced in the following year at the same theatre, Mr Jones showed an almost startlingly sudden access of talent. From this level he has never seriously declined, and in some plays, notably in *Michael and his Lost Angel* (1896), in that admirable comedy *The Liars* (1897), and in *Mrs Dane's Defence* (1900), he has risen well above it. Mr Sydney Grundy has produced since 1893 by far his most important original works, *The Greatest of These* (1896) and *The Debt of Honour* (1900). Mr R. C. Carton, breaking away from the somewhat laboured sentimentalism of his earlier manner, has given us since 1898 three light comedies of thoroughly original humour and of excellent literary workmanship—*Lord and Lady Algy*, *Wheels within Wheels*, and *Lady Huntworth's Experiment*. Mr Haddon Chambers, in *The Tyranny of Tears* (1899) and *The Awakening* (1901), has produced two plays of a merit scarcely even foreshadowed in his earlier efforts. Moreover, a new generation of playwrights has come to the front which, if it has not as yet produced any quite masterly work, has time before it in which to fulfil its high promise. Its most notable representatives are Mr J. M. Barrie, whose *Wedding Guest* (1900), amid many crudities, showed real power; Mrs Craigie ("John Oliver Hobbes"), who has produced in *The Ambassador* (1898) a comedy of fine accomplishment; and Mr H. V. Esmond, who has passed from light comedy in *One Summer's Day* (1897) to sentimental tragedy in *Grierson's Way* (1899), and back to social comedy in *The Wilderness* (1901). The indubitable though too self-sufficient talent of Mr George Bernard Shaw defies classification. Passing, often in one and the same play, from serious drama to the most whimsical extravaganza, it entirely subordinates the

portrayal to the criticism of life, or in other words, to the expression of Mr Shaw's very peculiar individuality. Two of his comedies, however, *Arms and the Man* (1894) and *The Devil's Disciple* (1898), have had some success on the American stage; and occasional performances have proved that the wit of *Candida* and *You Never Can Tell* is at least as effective in the theatre as in the pages of *Plays, Pleasant and Unpleasant* (1898).

It is not, of course, suggested that *The Second Mrs Tanqueray* was the cause of that enlargement in the aims and methods of drama which has marked the years since its production. It was rather the decisive symptom of a pre-existent tendency. Mr Pinero demonstrated to authors, managers, and the public the unreality of that superstition which declared the modern English stage foredoomed to intellectual impotence. Other playwrights have succeeded, not by imitating him, but simply by availing themselves of the extension of frontier which, at two strides, as it were, marked by *The Profligate* and *Mrs Tanqueray*, he had vindicated for his craft. These two plays constituted an "effective occupation" of territory hitherto supposed inaccessible to the British dramatist—territory which now belongs to the public domain. To the unprejudiced observer it is manifest that the English drama of to-day stands on a totally different plane from that which it occupied twenty-five, or even fifteen, years ago. Yet it is still far from taking the place it ought to take in the intellectual life of the country. For one thing, it has still to struggle against unfortunate financial conditions, of which the most hampering is the necessity of appealing to an enormous public on pain of finding none at all. There is no middle course between a continuous run of at least three months and absolute failure. If only as offering a loophole of escape from the pressure of the long-run system, the endowed Repertory Theatre for which Professor Ward sighed in concluding, in 1877, his article DRAMA in the ninth edition of this work, is as much as ever to be desiderated. Some of the limitations of the modern English drama, however, are to be traced, not to external conditions, but to a certain narrowness of outlook on the part of the authors themselves, combined with a deficiency in what may be called, in the largest sense of the term, philosophic grasp of life. Most of the leading playwrights of Great Britain have served their apprenticeship either as actors or as adapters and melodramatists. They have begun at the bottom of the ladder, and have in their early years acquired technical skill (some of which they have afterwards had to unlearn) to the comparative exclusion of intellectual culture. Only a few have approached the special work of the dramatist from the side of general literary accomplishment. Chief among the latter class stands Mr Stephen Phillips (*b.* 1866), who had won distinction as a poet before his *Paolo and Francesca* (published 1899) gave proof of his power as a dramatist. The success of his tragedy of *Herod* (1900) has awakened hopes of a revival of poetic drama, which have been strengthened by the almost simultaneous revival in the younger generation of actors of the power of speaking verse with smoothness and sonority.

***United States.***

The American drama has during the past decade shown a progressive tendency as marked, if not quite as vigorous, as that which we have been tracing in England. Down to about 1890 the influence of France had been even more predominant in America than in England. The only American dramatist of eminence, Mr Bronson Howard (*b.* 1842), was a disciple, though a very able one, of the French school. A certain stirring of native originality manifested itself during the 'eighties, when a series of semi-improvised farces, associated with the names of two actor-managers, Harrigan and Hart, depicted low life in New York with real observation, though in a crude and formless manner. About the same time a native style of popular melodrama began to make its appearance—a play of conventional and negligible plot, which attracted by reason of one or more faithfully observed character-types, generally taken from country life. *The Old Homestead*, written and acted by Denman Thompson, was the most popular play of this class. Rude as it was, it distinctly foreshadowed the subsequent course of development. The drama, indeed, has simply followed in the track of fiction. Almost every district and every city in the Union has its novelist-interpreter who faithfully studies, with more or less ability, local character-types and their environment; and it is in similarly attaching itself to definite localities that the American drama has done its best work. Ibsen has had little or no influence in America, but the stimulus of the Théâtre Libre has been felt to some extent in various experimental enterprises. It was at a sort of Free Theatre in Boston that Mr James A. Herne (*d.* 1901) produced in 1891 his realistic drama of modern life, *Margaret Fleming*, which did a great deal to awaken the interest of literary America in the theatrical movement. Mr Herne, an actor and a most accomplished stage-manager, next produced a drama of rural life in New England, *Shore Acres* (1892), which made an immense popular success. It was a play of the *Old Homestead* type, but very much more coherent and artistic. His next play, *Griffith Davenport* (1898), founded on a novel, was a drama of life in Virginia during the Civil War, admirable in its strength and quiet sincerity; while in his last work, *Sag Harbour* (1900), Mr Herne returned to the study of rustic character, this time in Long Island. Mr Herne showed human nature in its more obvious and straightforward aspects, making no attempt at psychological subtlety; but within his own limits he was an admirable craftsman. The same preoccupation with local colour is manifest in the plays of Mr Augustus M. Thomas, a writer of genuine humour and originality. His localism announces itself in the very titles of his most popular plays—*Alabama*, *In Mizzoura*, *Arizona*. Mr Clyde Fitch, a young playwright of indubitable ability, has made experiments in several directions, notably in that of quasi-historical drama (*Nathan Hale*, *Barbara Frietchie*), but his chief bent seems to be in the direction of social drama on the French model. Mr William Gillette, a very popular actor, has written several melodramas of such marked originality and power as almost to raise them to the rank of literature. It must be said, however, that the financial conditions of the American stage are even more hostile to original drama than those which we have noted in England, while the fact that American managers have not only the French but the English stage to draw upon, tends to restrict the field open to native endeavour.

***Literary drama.***

It remains to say a few words of the English literary drama, as opposed to the acted drama. The two classes are not nearly so distinct as they once were; but plays continue to be produced from time to time which are wholly unfitted for the theatre, and others which, though they may be experimentally placed on the stage, make their appeal rather to the reading public. Concluding in 1877 his survey of the English drama, Dr Ward remarked, "The latest English dramatic poet is Tennyson." The late Poet Laureate had in his old age attempted an art which is scarcely to be mastered after the energy of youth has passed away. He continued to the last to occupy himself more or less with drama, and all his plays, except *Harold*, found their way to the stage. *The Cup* and *Becket*, as we have seen, met with a certain success, but *The Promise of May* (1882),

an essay in contemporary drama, was a disastrous failure, while *The Falcon* (1879) and *The Foresters* (acted by an American company in 1893) made little impression. Lord Tennyson was certainly not lacking in dramatic faculty, but he worked in an outworn form which he had no longer the strength to renovate. Mr Swinburne has continued now and then to cast his creations in the dramatic mould, but it cannot be said that his dramas have attained either the vitality or the popularity of his lyrical poems. *Mary Stuart* (1881) brought his Marian trilogy to a close. In *Locrine* he produced a tragedy in heroic couplets—a thing probably unattempted since the age of Dryden. *The Sisters* is a tragedy of modern date (1816), with a mediæval drama inserted by way of interlude. *Rosamund, Queen of the Lombards* (1899), perhaps approached more nearly than any of his former works to the concentration essential to drama. It may be doubted, however, whether his copious and ebullient style could ever really subject itself to the trammels of dramatic form. Of other dramas on the Elizabethan model, the most notable, perhaps, have been the works of two ladies who adopt the pseudonym of "Michael Field." They have written *Callirrhoë* (1884), *Brutus Ultor* (1887), and many other dramas, all of which show considerable power of imagination and expression, but are burdened by a deliberate archaism both of technique and style. Mr Alfred Austin has put forth several volumes in dramatic form, such as *Savonarola* (1881), *Prince Lucifer* (1887), and *England's Darling* (1896). They are laudable in intention and fluent in utterance. Notable additions to the purely literary drama were made by Mr Robert Bridges in his *Prometheus* (1883), *Nero* (1885), *The Feast of Bacchus* (1889), and other solid plays in verse, full of science and skill, but less charming than his lyrical poems. Sir Lewis Morris made a dramatic experiment in *Gycia*, but has not been encouraged to repeat it.

Poets of a younger generation have contributed some noteworthy works to the literary drama. Mr John Davidson's volume of *Plays* contains more poetry, perhaps, than drama properly so called, but is by no means a negligible production. In his earlier efforts, such as *An Unhistorical Pastoral*, Mr Davidson gave himself up to luxuriant imitation of Shakespeare in his most luxuriant mood; but there is strong writing in *Smith: a Tragedy* (1886), and genuinely dramatic vigour in *Bruce: a Chronicle Play* (1884). *Scaramouch on Naxos* (1888) is a somewhat too fantastic fantasy. Mr W. B. Yeats has written two plays on subjects borrowed from Irish folklore: *The Countess Kathleen* (1892) and *The Land of Heart's Desire* (1894). They are tender and exquisite poems, with a real element of drama in them, and both have met with some acceptance on the stage. "John Oliver Hobbes" (Mrs Craigie) has produced in *Osbern and Ursyne* (1899) a tragedy of considerable merit, marred by obscurities of style. Mention has already been made of the plays of Mr Stephen Phillips, which belong no less to theatrical than to literary drama. From the point of view of literary history, Mr Phillips may be regarded as a rebel against the supremacy of the Elizabethan tradition in English poetic drama. While choosing romantic subjects, he seeks to give them classic dignity, repose, and compression. He has shown a gift of dramatic story-telling unequalled among the poets of our time, while in his diction he has avoided at once the obscurity arising from over-conciseness and the tedium involved in redundant verbiage.

The collaboration of Robert Louis Stevenson with Mr William Ernest Henley produced a short series of interesting experiments in drama, two of which, *Beau Austin* (1883) and *Admiral Guinea* (1884), have more than a merely experimental value. The former is an emotional comedy, treating with rare distinction of touch a difficult, almost an impossible, subject; the latter is a nautical melodrama, raised by force of imagination and diction into the region of literature. It is much to be regretted that, in the later years of Stevenson's life, his health, and the absence from England which it entailed, should have kept the collaborators so much apart as to prevent the continuance of the series.

The most prolific and, it would seem, the ablest of the literary contingent—of those, that is to say, who do not approach the drama primarily through the stage-door—is Mr George Bernard Shaw, whose three volumes, *Plays, Pleasant and Unpleasant*, and *Plays for Puritans*, contain some very remarkable writing. After some insignificant and needlessly disagreeable 'prentice-pieces, Mr Shaw produced, in *Mrs Warren's Profession*, a drama of remarkable, though crude, power, and in *Arms and the Man* a brilliant comedy-extravaganza. The same description applies to *You Never Can Tell* and *Captain Brassbound's Conversion;* while *The Devil's Disciple* is a satiric melodrama, and *Cæsar and Cleopatra* a curious compound of historic drama with topical burlesque. Mr George Moore has made two experiments in drama—*The Strike at Arlingford* and *The Bending of the Bough.* The latter, with its somewhat ill-digested symbolism, is a characteristic outcome of the Irish Literary Movement, to which we also owe Mr Edward Martyn's sombre but able drama, *The Heather Field*, and his tragic fantasy entitled *Maeve.* Other published plays of interest are Mr Alfred Sutro's *Cave of Illusion*, and Mr Gilbert Murray's *Carlyon Sahib* and *Andromache*, the latter a noteworthy attempt to go to the very sources of Greek inspiration and treat a saga-theme in the saga spirit. (W. A.)

**French drama.**

*French Drama* (since 1875).—The last twenty-five years of the 19th century witnessed an important change in the constructive methods, as well as in the moral tendencies, of the French playwrights. The old favourites disappeared; new men came to the front. Various influences, some proceeding from foreign quarters, some closely connected with the evolution of national thought and manners, have been working, not very harmoniously, together, often in totally opposite directions. It would be rash, and indeed almost impossible, to offer a general opinion on the French drama of this period, as no identity of moral purpose, and hardly any artistic relationship, can be traced between the leading writers; but it may be profitable to note the different experiments which have been tried, more or less successfully, during the last quarter of a century, and the crisis through which the French theatre has been slowly and laboriously working its way towards an unknown future.

Of the two leading dramatists who reigned supreme over the *haute comédie* in 1875, one, Emile Augier, had almost ended his career; but the other, Alexandre Dumas, was to maintain his ascendancy for many years longer. Sardou's fertility of invention, and extraordinary cleverness at manipulating a complicated intrigue, were also greatly admired, and much was expected from Edouard Pailleron's brilliant and—as it seemed—inexhaustible wit in satirizing the whims and weaknesses of high-born and highly cultured society. Alexandre Dumas had created and still monopolized the problem play, of which *Le Demi-Monde, Le Fils Naturel, La Question d'Argent, Les Idées de Madame Aubray, La Femme de Claude, Monsieur Alphonse, La Visite de Noces, L'Etrangère, Francillon*, and *Denise* may be mentioned as the most characteristic specimens. The problem play is the presentation of a particular case, with a view to a general conclusion on some important question

of human conduct. This afforded the author, who was, in his way, a moralist and a reformer, excellent opportunities for humorous discussions and the display of that familiar eloquence which was his greatest gift and most effective faculty. Among other subjects, the social position of women had an all-powerful attraction for his mind, and many of his later plays were written with the object of placing in strong relief the remarkable inequality of the sexes, both as regards freedom of action and responsibility, in modern marriage. Like all the dramatists of his time, he adhered to Scribe's mode of play-writing—a mixture of the *drame bourgeois*, as initiated by Diderot, and the comedy of character and manners, long in vogue—from the days of Molière, Regnard, Destouches, and Marivaux, down to the beginning of the 19th century. In his prefaces Dumas often undertook the defence of the system which, in his estimation, was best calculated to serve the purpose of the artist, the humorist, and the moralist—a dramatist being, as he conceived, a combination of the three.

Though the majority of French playgoers continued to side with him, and to cling to the time-honoured theatrical beliefs, a few young men were beginning to murmur against the too elaborate mechanism and artificial logic. Scribe and his successors, whose plays were a combination of comedy and drama, were wont to devote the first act to a brilliant and witty presentation of personages, then to crowd the following scenes with incidents, until the action was brought to a climax about the end of the fourth act, invariably concluding, in the fifth, with an optimistic *dénouement*, just before midnight, the time appointed by police regulations for the closing of playhouses. At the same time a more serious and far-reaching criticism was levelled at the very principles on which the conception of human life was then dependent. A new philosophy, based on scientific research, had been gradually gaining ground and penetrating the French mind. A host of bold writers had been trying, with considerable firmness and continuity of purpose, to start a new kind of fiction, writing in perfect accordance with the determinist theories of Auguste Comte, Darwin, and Taine. The long-disputed success of the Naturalistic School carried everything before it during the years 1875–1885, and its triumphant leaders were tempted to make the best of their advantage by annexing a new province and establishing a footing on the stage. In this they failed signally, either when they were assisted by professional dramatists or when left to their own resources. It became evident that Naturalism, to be made acceptable on the stage, would have to undergo a special process of transformation and be handled in a peculiar way. M. Henry Becque succeeded in embodying the new theories in two plays, which at first met with very indifferent success, but were revived at a later period, and finally obtained permanent recognition in the French theatre—even with the acquiescence of the most learned critics, when they discovered, or fancied they discovered, that M. Becque's comedies agreed, in the main, with Molière's conception of dramatic art. In *Les Corbeaux* and *La Parisienne* the plot is very simple; the episodes are incidents taken from ordinary life. No extraneous character is introduced to discuss moral and social theories, or to acquaint us with the psychology of the real *dramatis personæ*, or to suggest humorous observations about the progress of the dramatic action. The characters are left to tell their own tale in their own words, which are sometimes very comical, sometimes very repulsive, but purport to be always true to nature. Human will, which was the soul and mainspring of French tragedy in the 17th century, and played such a paramount part in the *drame bourgeois* and the *haute comédie* of the 19th, appears in M. Becque's plays to have fallen from its former exalted position and to have ceased to be a free agent. It is a mere passive instrument to our inner desires and instincts and appetites, which, in their turn, obey natural laws. Thus, in M. Becque's comedies, as in the old Greek drama, Destiny, not man, is the chief actor, the real but unseen protagonist.

M. Becque was not a prolific writer, and when he died, in 1899, it was remarked that he had spent the last ten years of his life in comparative inactivity. But during these years his young and ardent disciples had spared no effort in putting their master's theories to the test. It had occurred to a gifted and enterprising actor-manager, named Antoine, that the time had come for trying dramatic experiments in a continued and methodical manner. For this purpose he gathered around him a number of young authors, and produced their plays before a select audience of subscribers, who had paid in advance for their season-tickets. The entertainment was a strictly private one. In this way M. Antoine made himself independent of the censors, and at the same time was no longer obliged to consider the requirements of the average playgoer, as is the case with ordinary managers, anxious, above all things, to secure long runs. At the Théâtre Libre the most successful play was not to be performed for more than three nights.

The reform attempted was to consist in the elimination of what was contrary to nature in Dumas's and Augier's comedies: of the *intrigue parallèle* or underplot, of the over-numerous and improbable incidents which followed the first act and taxed the spectator's memory to the verge of fatigue; and, lastly, of the conventional *dénouement* for which there was no justification. A true study of character was to take the place of Sardou's complicated fabrications and Dumas's problem plays. The authors would present the spectator with a fragment of life, but would force no conclusion upon him at the termination of the play. The reformation in histrionic art was to proceed apace. The actors and actresses of the preceding period had striven to give full effect to certain witty utterances of the author, or to preserve and to develop their own personal peculiarities or oddities. M. Antoine and his fellow-artists did their best to make the public realize, in every word and every gesture, the characteristic features and ruling passions of the men and women they were supposed to represent.

It was in the early autumn of 1887 that the Théâtre Libre opened its doors for the first time. It struggled on for eight years amidst unfailing curiosity, but not without encountering some adverse, or even derisive, criticism from a considerable portion of the public and the press. The Théâtre Libre brought under public notice such men as Courteline and George Ancey, who gave respectively, in *Bonbouroche* and *La Dupe*, specimens of a comic vein called the "*comique cruel*." M. Fabre, in *L'Argent*, approached, if not surpassed his master, Henry Becque. M. Brieux, in *Blanchette*, gave promise of talent, which he has since in a great measure justified. In *Les Fossiles* and *L'Envers d'une Sainte*, by M. François de Curel, were found evidences of dramatic vigour and concentrated energy, allied with a remarkable gift for the minute analysis of feeling. M. Antoine's activity was not exclusively confined to the efforts of the French Naturalistic School; he included the Norwegian drama in his programme, and successively produced several of Ibsen's plays. They received a large amount of attention from the critics, the views then expressed ranging from the wildest enthusiasm to the bitterest irony. Francisque Sarcey was decidedly hostile, and M. Jules Lemaître, who ranked next to him in authority, ventured to suggest that Ibsen's ideas were nothing better than long-discarded social and literary paradoxes, borrowed from Pierre Leroux through George Sand, and returned to

the French market as novelties. It was only quite recently that *John Gabriel Borckmann* received a warm tribute of admiration from M. Emile Faguet, the talented successor of M. Jules Lemaître on the *Journal des Débats.* Without entering into a close consideration of the subject, it may be affirmed that up to the year 1902 Ibsen had not yet been understood by the French public at large, though his influence could be clearly traced on thoughtful men like M. Paul Hervieu and M. François de Curel.

The authors of the Théâtre Libre were sadly wanting in tact and patience. They went at once to extremes, and, while trying to free themselves from an obsolete form of drama, fell into a state of anarchy. If a too elaborate plot is a fault, no plot at all is an absurdity. The old school had been severely taken to task for devoting the first act to the delineation of character, and the delineation of character was now found to have extended over the whole play; and worse still, most of these young men seemed to find pleasure in importing a low vocabulary on to the stage; they made it their special object to place before the spectator revolting pictures of the grossest immorality. In this they were supported by a knot of noisy and unwise admirers, whose misplaced approval largely contributed towards bringing an otherwise useful and interesting undertaking into disrepute. The result was that, after the lapse of eight years, the little group collected round M. Antoine had lost in cohesion and spirit, that it was both less hopeful and less compact than it had been at the outset of the campaign. But some authors who had kept aloof from the movement were not slow in reaping the moral and intellectual profit of these tentative experiments. Among them must be cited M. George de Porto-Riche, M. Henri Lavedan, M. Paul Hervieu, M. Maurice Donnay, and M. Jules Lemaître. The first-named is a veteran writer, but in *Amoureuse* he revealed qualities unsuspected by those who witnessed his first literary efforts. M. Henri Lavedan, who has succeeded Henri Meilhac at the French Academy, has also inherited some of that writer's brilliant faculty for light comedy and the portrayal of the gay Parisian world of pleasure and fashion. There is no wit, no humour, in M. Paul Hervieu, nothing bright or refreshing in his manner. In two successive plays, *Les Tenailles* and *La Loi de l'Homme,* he has made evident to all but prejudiced minds the inadequacy and injustice of the marriage laws now existing in France. It is admitted by fastidious judges that the third act of *Les Tenailles* is a model of masterly simplicity and dramatic concentration. M. Donnay, in his play entitled *Amants,* has presented a fascinating love-story, which goes through all its natural phases without the addition of a single incident borrowed from old scenic traditions. In his more recent works he has won only partial applause. He is still a master of light, easy-going dialogue, but his style and treatment become conventional and constrained when he attempts drama. M. Jules Lemaître, in his double capacity of critic and playwright, seems to have overlooked the salutary example set him by Maître Jacques, who was both cook and coachman in the household of Harpagon. He should have been warned against letting his two callings clash. His dramatic works may be described as successful and clever efforts in all branches of the art, from tragedy down to farce, but he has achieved no decisive triumph in any particular field, perhaps because his freedom of invention has been, to some extent, hampered by his critical faculties, or diverted towards the imitation of too many different lines. Alone among the authors of the Théâtre Libre, M. Brieux has come to the front and secured an assured position on the regular stage. Instead of attacking the vices and follies of his times, he has made a name by satirizing the weak points or the wrong application of certain fundamental principles by which modern institutions are supported. He mocked at universal suffrage in *L'Engrenage,* at art in *Ménages d'Artistes,* at popular instruction in *Blanchette,* at charity in *Les Bienfaiteurs,* at science in *L'Evasion,* and, finally, at law in *La Robe Rouge.* Of *Les Trois Filles de M. Pupont,* one is an old maid with a strong bent towards mysticism, another is a star in the demi-monde, and the third is married. Neither religion, nor free love, nor marriage has made one of the three happy. The strange fact about M. Brieux is that he propounds his uncomfortable ideas with an incredible amount of dash and spirit.

All the plays written by the above-mentioned authors, and by those who follow in their steps, have been said to constitute the "new comedy." But one may question the advisability of applying the same name to literary works which present so little, if any, family likeness. It was tacitly agreed to remove the intricacies of the plot and the forced *dénouement.* But no one will trace in those plays the uniformity of moral purpose which would justify us in comprising them under the same head, as products of the same school. Then, before the Naturalistic, or half-Naturalistic, School had attained to a practical result or taken a definite shape, a wave of Romanticism swept over the French public, and in a measure brought back the old artistic and literary dogmas propounded by Victor Hugo and the generation of 1830. Signs of an approaching revival in French dramatic poetry have not been lacking during the last few years. The success of *La Fille de Roland,* by the Vicomte de Bornier, was restricted to the more cultivated classes, but the vogue of M. Jean Richepin's *Chemineau* was at once general and lasting. *Cyrano de Bergerac,* produced in the last days of 1897, brought a worldwide reputation to its young author, M. Edmond Rostand. This play combines sparkling wit and brilliancy of imagination with delightful touches of pathos and delicate tenderness. It was assumed that M. Edmond Rostand was endowed to an extraordinary degree both with theatrical genius and the poetic faculty. *L'Aiglon* fell short of this too favourable judgment. It is more a dramatic poem than a real drama, and the author handles history with the same childish incompetence and inaccuracy as Hugo did in *Cromwell,* in *Ruy Blas,* and *Hernani.* The persistent approbation of the public seems, however, to indicate a growing taste for poetry, even when unsupported by dramatic interest—a curious symptom among the least poetical of modern European races.

To sum up, the French, as regards the present condition of their drama, are confronted with two alternative movements. Naturalism, furthered by science and philosophy, is contending against traditions three centuries old, and seems unable to crystallize into masterly works; while romantic drama, founded on vague and exploded theories, has become embodied in productions of real artistic beauty, which have been warmly welcomed by the general playgoer. It should nevertheless be noted that in *Cyrano* and *L'Aiglon* human will, which was the mainspring of Corneille's tragedy and Hugo's drama, tries to reassert itself, but is baffled by circumstance, and has to submit to inexorable laws. This shows that the victorious school will have to reckon with the doctrines of the defeated party, and suggests that a determinist theatre may be the ultimate outcome of a compromise. (A. Fi.)

**Drammen,** a seaport town of Norway, partly in co. Buskerud, partly in co. Jarlsberg and Laurvik, 33 miles by rail south-west from Christiania. In 1899 it owned a mercantile fleet of some 140 vessels of 88,700 tons aggregate, and its total foreign trade was valued at over one million sterling (exports, £704,100; imports, £373,750), as

against £530,000 in 1887. The exports consist principally of timber (7,000,000 cubic feet in 1898) and wood-pulp (136,250 tons), with paper, ice, and a little cobalt and nickel ore. Of these 58 per cent. of the timber and 64 per cent. of the wood-pulp go to Great Britain. The imports consist chiefly of coal (127,000 tons in 1898) from Great Britain and machinery from Germany. Population (1875), 18,643; (1900), 23,091.

**Draughts.**—The last decade of the 19th century witnessed a remarkable increase in the popularity of the game of draughts (known also in the United States as "checkers"). This was the result of several causes, chief among which were the establishment of championship tournaments, the institution of leagues similar to the football leagues, the insertion of "draughts columns" in several weekly newspapers, and the publication of the late James Lees's *Guide to the Game of Draughts*, a handbook at once accurate, fairly well arranged, and cheap. To these causes, and to the correspondence tournaments conducted by the editors of draughts columns, is also to be attributed the improvement which took place in the standard of play of the average player, an improvement which manifested itself both in the variety of openings played and in more accurate mid-game play.

*Championships.*

In January 1893 the first of the annual tournaments for the championship of Scotland was held. These tourneys deservedly rank first among the events of the draughts year, on account of the number and ability of Scottish players and the high standard of play which they have maintained throughout the competitions. The following is a list of the winners since the competition was instituted:—

| | |
|---|---|
| 1893. W. Bryden, Glasgow. | 1898. H. Freedman, Glasgow. |
| 1894. R. Stewart, Blairadam. | 1899. H. Freedman, Glasgow. |
| 1895. R. Stewart, Blairadam. | 1900. R. Stewart, Blairadam. |
| 1896. R. Jordan, Edinburgh. | 1901. R. Stewart, Blairadam. |
| 1897. J. Ferrie, Coatdyke. | 1902. R. Stewart, Blairadam. |

The series of tournaments for the championship of England commenced in 1885. The English Draughts Association now holds these competitions biennially. The following is a list of winners:—

| | |
|---|---|
| 1885. J. Smith, Spennymoor. | 1898. W. Gardner, Leeds. |
| 1891. H. Christie, Sunderland. | 1900. A. Hynd, Manchester. |
| 1892. A. Jordan, London. | |

Similar tournaments are held in the Australian colonies and in New Zealand, but not in America, though the game has obtained a firm hold both in Canada and in the United States. In these countries the championship is decided by matches.

In 1894 James Ferrie of Coatdyke challenged James Wyllie, the famous "Herd Laddie," for the title of Champion Draughts Player of the World, an honour which the latter had held since 1877. Ferrie won easily by thirteen games to six, but no doubt the severity of the defeat was in part due to Wyllie's advancing years. Ferrie, however, did not long retain his honours. In the Scottish tournament held in January 1896 he met Richard Jordan and was defeated by him. In consequence a match was arranged between them for Ferrie's title of Champion of the World, and the result was a win for Jordan by four games to three. In 1897 Jordan successfully defended his recently won title against R. Stewart, who had made a name for himself in the Scottish championship tournaments. The match, which was played at Edinburgh, resulted in a victory for Jordan by four wins to two. In 1900 the champion visited Boston, U.S.A., in response to a challenge from C. F. Barker, the American champion. The result of the contest which ensued was a draw of two wins each, Jordan thus retaining his title.

In 1884 the first international match between Scotland and England took place. It resulted in so decisive a victory for the north-countrymen that the contest was not renewed until ten years later. The matches played in 1894 and 1899 also went strongly in favour of the Scotsmen, but the disparity between the teams was not so marked as in the first match, a result which may be attributed rather to improvement in the skill of the English players than to any falling off on the part of their opponents. The following are the scores in the three matches:—

1884. Scotland won by 36 games to 7.
1894. Scotland won by 29 games to 15.
1899. Scotland won by 42 games to 25.

*Computation of draughts variations.*

An objection frequently urged against draughts, and especially as compared with chess, is that the game lacks scope for variety. The charge is easily disproved by a rough computation of the variations possible at draughts. We see that the first player has seven different ways in which he may make his first move, and that to each of these seven moves his opponent has seven possible replies, making in all 49 "openings." Two of these openings, however (9–14, 21–17, and 10–14, 21–17), are unsound, since white loses a piece without any compensating gain in position, thus reducing the number of recognized "openings" to 47. Taking the Jordan-Ferrie and Jordan-Barker match-games as the standard, the average number of moves in a game is over 50—say 52 for convenience of calculation,—and, as may be proved by an examination of the specimen games given below, it is within the mark to say that there are, on an average, four possible variations at each point in the game after the opening is formed. In computing the latter average, moves which would obviously result in the loss of a piece without any corresponding gain in position have been neglected. To ascertain, therefore, the total number of possible moves, the number of openings must be multiplied by $4^{50}$. The logarithm of $47 \times 4^{50}$ shows the expression to represent a number of thirty-one digits, a number so large that the imagination utterly fails to grasp its significance.

Players have been accustomed to consider the unlimited scope for variety which the game possesses as an unmixed benefit, the reason being that it tends to foster original play. There is, however, another side to the question. Suppose a player to hold such a position that he has the choice of four moves, and that his opponent may reply to each of these in four different ways. Sixteen possible positions may thus be formed, and if, as is probable, they each permit of as many continuations as the first-mentioned position, we see that the first player must examine 256 moves in order to make sure of his ground four moves ahead. The best chess and draughts players agree that, to play well, one should look ten moves ahead. Obviously, then, a player cannot possibly examine all continuations open to him, nor indeed can he do more than select a few of the most likely, relying on his judgment of position to aid him in his choice. The drawback undoubtedly exists in both chess and draughts, but of course it applies, in theory at least, with greater force to the former game, from the fact that an average chess position will give more possible continuations than a similar position at draughts.

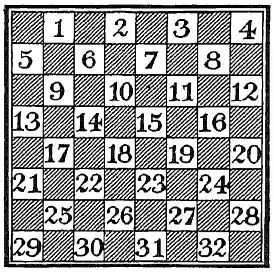
Draughts-players claim, among minor considerations, that their game possesses, for the busy man, an advantage over chess in that a good game—say one worthy of publication—occupies less time than a similar game at

chess. This is probably the case; but on the other hand, it must be pointed out that chess is the more picturesque in appearance; and this is a fact the value of which should not be underestimated in considering the game's claim to popular favour or its desirability as a pastime.

Both games, played in moderation, undoubtedly assist the mind towards a habit of concentrated and consecutive thought, coupled with carefulness in matters of detail; both games allow almost unlimited scope for brilliant and critical combinations. It is worthy of note, perhaps, that while so far the bulk of draughts-players have been members of the working and lower middle classes, the majority of chess-players have been drawn from the middle and upper classes.

The calculations given above as to the variation possible at draughts will convince most inquirers that no player, however expert at the game, could claim to know the replies to every possible move. Were further proof necessary, one might find it in the fact that more than one-third of the games played in the Scottish Championship Tournament of 1901 resulted in wins; and this proportion is not affected even if the games of the first round, in which less able players were more likely to be engaged, be omitted.

***Draughts "openings."*** In different districts and at different times the greatest diversity of opinion has existed regarding the relative strength of the various openings. It used to be generally held that for the black side 11–15 was considerably superior to any other opening move. Towards the end of the 19th century this view became much modified, and though 11–15 still remained the favourite, it was recognized that 10–15, 9–14, and 11–16 were little, if at all, inferior; 10–14 and 12–16 were rightly rated as somewhat weaker than the four moves named above, whilst 9–13, the favourite of the "unscientific" player, was found to be weakest of all.



The white replies to 11–15 have gone through many vicissitudes. The seven possible moves have each at different times figured as the general favourite. Thus 24–19, which more thorough analysis proved to be the weakest of the seven, was at one period described by the title of "Wyllie's Invincible." In course of time it came to be regarded as decidedly weak, and doubts began to be entertained as to whether the opening even admitted of a draw for white, its name being, in consequence, dropped for the less pretentious title of "Second Double Corner." In the Scottish Tournament of 1894 the opening was played between Ferrie and Stewart, and the latter won the game with white. The new play then introduced has stood the test of analysis, and the opening now ranks as but little inferior to those formed by the other possible replies, its main drawback consisting in the lack of scope for variations favourable to the player of the white pieces. The 21–17 reply to 11–15 was introduced by Wyllie, who was so successful with it that it became known as the "Switcher." The opening is perhaps lacking in the solid strength of some of the others, but it so abounds in traps as to be well worthy of its name. The other five replies to 11–15, namely, 24–20, 23–19, 23–18, 22–18, and 22–17, are productive of games which are generally held to give equal chances to both sides.

The favourite replies to 10–15 are 23–18, 22–18, and 21–17, but they do not appear to be appreciably stronger than the others, with the possible exception of 24–20.

In response to 11–16, 23–18 is held to give white a trifling advantage, but it is more apparent than real. With the exception of 23–19, which is weak, the other replies are of equal strength, and are only slightly, if at all, inferior to the more popular 23–18.

Against 10–14 the most popular move is 22–17, which gives white an advantage. Next in strength come 22–18 and 24–19. 23–18 is weak.

The strongest reply to 12–16 is 24–20. The others, except 23–19, which is weak, give no initial advantage to either side.

As already mentioned, 9–13 is black's weakest opening move, both 22–18 and 24–19 giving white a distinct advantage. Nevertheless 9–13 is a favourite début with certain expert players, especially when playing with inferior opponents.

The three following games are typical examples of the play arising from three of the most frequently played openings:—

Game No. 1.—"Ayrshire Lassie" Opening.

| | | | | | |
|---|---|---|---|---|---|
| *a* 11–15 | 25–18 | 10–15 | 22–17 | *b* 15–18 | 24– 6 |
| *a* 24–20 | 3– 8 | 23–19 | 13–22 | 24–20 | 2– 9 |
| 8–11 | 26–22 | 6–10 | 26–17 | 18–27 | 17–10 |
| 28–24 | 5– 9 | *c d* 27–23 | 11–16 | 31–24 | 8–11 |
| 9–13 | 30–26 | 9–14 | 20–11 | 16–23 | Drawn. |
| 22–18 | 1– 5 | 18– 9 | 7–16 | 20–16 | R. Jordan. |
| 15–22 | 32–28 | 5–14 | 29–25 | 12–19 | |

*a.* 11–15, 24–20 forms the "Ayrshire Lassie" opening, so named by Wyllie. It is generally held to admit of unusual scope for the display of critical and brilliant combinations.

*b.* 16–20, 25–22, 20–27, 31–24, 8–11, 17–13, 2–6, 21–17, 14–21, 22–17, 21–25, 17–14, 10–17, 19–1. Drawn. R. Jordan.

| 26–23 | 28–19 | 20–16 | 7–11 | 14–10 | 15–10 |
| 9–14 | 2– 6 | 6–10 | 19–24 | 26–23 | 23–18 |
| 18– 9 | 20–11 | 16–11 | 11–18 | 10– 7 | 10–15 |
| 5–14 | 8–24 | 10–15 | 24–27 | 4– 8 | 20–16 |
| 29–25 | 27–20 | 11– 7 | 18–15 | 7– 3 | 15–22 |
| 11–16 | 10–15 | 14–18 | 27–31 | 8–12 | 16– 7 |
| 20–11 | 31–26 | 7– 3 | 22–18 | 3– 7 | Drawn. |
| 7–16 | 15–19 | 18–23 | 31–27 | 27–24 | A. B. Scott |
| 24–20 | 23–16 | 3–7 | 18–14 | 7–11 | *v.* |
| 15–24 | 12–19 | 23–30 | 30–26 | 24–20 | R. Jordan. |

(*d*)

| | | | | | |
|---|---|---|---|---|---|
| 19–16 | 7–10 | 23–19 | 11–15 | 16–11 | 25–30 |
| 12–19 | 6– 1 | 15–24 | 27–24 | 18–25 | 20–16 |
| 22–17 | 9–14 | 28–19 | 22–25 | 17–14 | Drawn. |
| 15–22 | 26–23 | 8–11 | 29–22 | 10–17 | R. Jordan. |
| 24– 6 | 11–15 | 19–16 | 14–18 | 21–14 | |

Game No. 2.—"Kelso-Cross" Opening.

| | | | | | |
|---|---|---|---|---|---|
| *a* 10–15 | 8–12 | 13–22 | 5– 9 | 14–18 | 22–25 |
| *a* 23–18 | 25–21 | 26–17 | 20–16 | 17–14 | 29–22 |
| 12–16 | 1– 6 | *d* 19–26 | 2– 7 | 10–17 | 17–26 |
| 21–17 | 32–27 | 30–23 | 24–19 | 21–14 | 5– 1 |
| 9–13 | 12–16 | 15–22 | 15–24 | 6–10 | 26–30 |
| 17–14 | 27–23 | 24–19 | 23–19 | 14– 9 | 1– 5 |
| 16–19 | 7–10 | 9–14 | 24–27 | 10–14 | 30–26 |
| 24–20 | 14– 7 | 19–12 | 31–24 | 19–15 | 5– 9 |
| 6– 9 | 3–10 | 11–15 | 9–13 | 14–17 | 26–23 |
| *b* 27–24 | *c* 22–17 | 28–24 | 24–20 | 9– 5 | Drawn. |
| | | | | | R. Jordan. |

*a.* These two moves form the "Kelso-Cross" opening.

*b.* 27–23 is also a strong line for white to adopt.

*c.* 30–25, 4–8, 18–14, 9–27, 22–18, 15–22, 24–15, 11–18, 20–4, 27–32, 26–17, 13–22, 4–8, 22–26, and black appears to have a winning advantage. R. Jordan.

*d.* Taking the piece on 18 first seems to lose, thus:—

| | | | | | |
|---|---|---|---|---|---|
| 15–22 | *e* 9–13 | 13–17 | 6– 9 | 5–14 | |
| 24– 8 | 17–14 | 23–18 | 14–10 | 10– 7 | White |
| 4–11 | 10–17 | 17–21 | 9–14 | 2– 6 | wins. |
| 31–27 | 21–14 | 28–24 | 18– 9 | 7– 2 | Dallas. |

*e.* 2–7, 27–24, 22–26, 23–18, 26–31, 18–15, 11–18, 20–2, 9–13, 2–9, 5–14, 24–19, 13–22, 30–26. White wins.

Game No. 3.—"Dundee" Opening.

| | | | | | |
|---|---|---|---|---|---|
| 12–16 | 11–15 | *c* 8–12 | 4– 8 | 9–14 | 1–26 |
| 24–20 | 20–11 | 17–13 | 18–15 | 26–22 | 31–22 |
| 8–12 | 7–16 | 5– 9 | 2– 7 | 14–17 | 19–23 |
| 28–24 | 24–20 | 22–18 | 30–26 | 21–14 | 13– 9 |
| 9–14 | *b* 16–19 | 15–22 | 10–14 | 18–23 | 12–19 |
| 22–17 | 23–16 | 25–18 | 29–25 | 27–18 | 9– 6 |
| 3– 8 | 12–19 | 14–23 | 14–18 | 6–10 | 7–11 |
| *a* 26–22 | 20–16 | 27–18 | 32–27 | 15– 6 | Drawn. |
| | | | | | R. Jordan. |

*a.* This move is the favourite at this point on account of its "trappiness," but 25–22 is probably stronger, thus: 25–22, 16–19, 24–15, 11–25, 29–22, 8–11, 17–13, 11–16, 20–11, 7–16, and white can with advantage continue by 27–24, 22–17, 23–19, or 22–18.

*b.* 15–19, 20–11, 8–15, 23–16, 12–19, 17–13, 5–9, 30–26, 4–8, 27–23, 8–12, 23–16, 12–19, 31–27, 1–5, 27–23, 19–24, 32–27, 24–31, 22–17. White wins. C. F. Barker.

| | | | | | |
|---|---|---|---|---|---|
| *c.* 8–11 | 27–18 | 15–18 | 14–10 | 24–27 | 7–10 |
| 16– 7 | 15–22 | 14–10 | 19–24 | 31–24 | 27–31 |
| 2–11 | 25–18 | 6–15 | 10– 7 | 16–20 | 10–26 |
| 22–18 | 10–15 | 17–14 | 18–23 | 3– 7 | 31–22 |
| 14–23 | 18–14 | 11–16 | 7– 3 | 20–27 | 30–25 |

Drawn. R. Stewart *v.* R. Jordan.

The problem diagrammed on next page is the simplest form of that known to draughts-players as the "First Position." It is of more frequent occurrence in actual play than any other end-game,

and is, besides, typical of a class of draughts problems which may be described as analytical, in contradistinction to "strokes."

Problem No. 1, by Wm. Payne.

WHITE.

White to move and win.

The above position is a fine example of another class of problems, namely, "strokes." It is formed from the "Paisley" opening, thus :—

| | | | | | |
|---|---|---|---|---|---|
| 11–16 | 22–17 | 11–16 | 26–19 | 9–13 | 15–10 |
| 24–19 | 9–13 | 25–21 | 4– 8 | 25–22 | *a* 2– 7 |
| 8–11 | 17–14 | 6– 9 | 29–25 | 7–11 | |
| 28–24 | 10–17 | 23–18 | 13–17 | 19–15 | |
| 16–20 | 21–14 | 16–23 | 31–26 | 12–16 | |

*a*. This forms the position on the diagram. The solution is as follows :—

| | | | | |
|---|---|---|---|---|
| 27–23 | 7–14 | 18– 9 | 14–23 | 26– 3 |
| 20–27 | 9– 6 | 5–14 | 21– 7 | 27–31 |
| 14– 9 | 1–10 | 23–18 | 3–10 | 3– 7 |

White wins. Jacques and Campbell.

*Recent Books on Draughts.*—The most important recent works on the game are Lees's *Guide to the Game of Draughts*, Hill's *Manual* (for beginners), Kear's reprint of Sturges' and Drummond's works on the game, and Gould's *Problem Book*. The *Encyclopædia of Draughts* bids fair to be a most useful compilation of the best published play on each opening. The principal magazines devoted to the game are the *Draughts World*, the *North American Checker Board*, both monthly publications, and the *Draughts Players' Quarterly Review*. (J. M. M. D. ; R. J.)

**Dráva** or **Drave,** one of the right-bank affluents of the Danube, 668 kilometres long. Its sources are in Tirol under the mountain of Rohrwald, at a height of 1670 metres, whence, after passing across Carinthia and Styria, it penetrates into Hungary, where it forms the frontier-line between the mother country and Croatia-Slavonia. From Villach it is navigable by rafts, but by steamers only from Barcs downwards, to a distance of 155 kilometres. Of its confluents only the Mura is considerable, but it receives the excess of many alpestrine ponds. The Dráva flows into the Danube close under the town of Eszék; at this spot it has already a breadth of 325 metres, and a depth of 6·5 metres. Because of its tortuousness from Barcs downwards it is defended by strong dams; its length is 501 kilometres, with a water-region of 47,191 square kilometres. In the escutcheon of the Kingdom of Hungary the Dráva is represented, with the Danube, the Tisza, and the Száva, as one of the largest rivers of the country.

**Dredging.**—The use of dredging plant and the selection of special appliances to be used in different localities and under varying circumstances requires the exercise of sound judgment on the part of the engineer. In rivers and estuaries where the bottom is composed of light soils, and where the scour of the tide can be so guided, by training walls or other works constructed at reasonable expense, as to keep the channel clear without dredging, it is manifest that dredging machinery, with its great cost for annual upkeep, should be as far as possible avoided. On the other hand, where the bottom consists of clay, rock, or other hard material, dredging must, in the first instance at any rate, be employed to deepen or widen the channel. In other instances, as in the Mississippi, a deep channel has for twenty years been maintained by jetties, with occasional resort to dredging to preserve the required channel section and to hasten its enlargement. The bar of the Mersey is 11 miles from the land, and the cost of training works would be so great as to render them impracticable; but by a capital expenditure of £120,000, and an annual expense of £20,000 for three years, the depth of water over the bar at low water has been increased by dredging from 11 ft. to 27 ft., the channel being 1500 ft. wide.

The effects of dredging operations upon the trade and prosperity of a port are nowhere more forcibly shown than in the case of Glasgow. In 1755 only small vessels with a draught of 3 ft. or less could reach Glasgow at high water of spring tides. Now vessels drawing 27 ft. come up on an ordinary tide. Formerly some of the river streets of Glasgow were often flooded; now, consequent upon the straightening, deepening, and widening of the river, flooding never occurs. In 1755 the rise of tide was only about 2 ft. 5 in. The extreme range of tide in Glasgow harbour is now 22 ft. These remarkable results have been due to the dredging carried on in the river Clyde. Between 1844 and 1897 the quantity of material dredged from the river and deposited outside its mouth was 50,721,710 cubic yards. The tonnage of goods imported and exported has risen from 1,023,216 tons in 1851 to 5,673,152 tons in 1897. Similar results have been obtained in the rivers Tyne and Tees. In the Tyne dredging amounting to 96,362,136 tons was done between 1860 and 1896, at a cost of £1,766,639; the average rate was 4·4 pence per ton, which, however, does not include interest upon the first cost of the dredging plant. The registered tonnage of ships clearing the port has risen from 3,120,265 tons in 1860 to 6,752,252 tons in 1896. At Rotterdam, Antwerp, Calais, Dunkirk, and Ostend equally satisfactory results have followed the dredging operations undertaken, and similar results have been obtained by the dredging works at the Sulina mouth of the Danube. It will be seen, therefore, that dredging operations form a most important de-

partment of civil engineering. It is proposed in this article to describe the improvements which have been made in dredgers and in dredging operations since the publication of the article in the ninth edition of this work (vol. vii., published in 1877), and to give the cost of dredging operations in various instances.

*Bucket-Ladder Dredgers.*—Barge-loading dredgers used formerly to be provided with two ladders, one on each side of the vessel or contained in wells formed in the vessel near each side. Two ladders were adopted, partly to permit the dredger to excavate material close to a quay or wall, and partly to enable one ladder to work while the other was being repaired. Of late years, however, bucket-ladder dredgers have generally been constructed with one central ladder working in a well, and this is the type now generally followed. Such dredgers are frequently made with the bucket ladder projecting either at the head or stern of the vessel, to enable it to cut its own way through a shoal or a bank, a construction which has been found very useful. In one modification of this method the bucket ladder is supported upon a traversing frame which slides along the fixed framing of the dredger and moves the bucket ladder forward as soon as it has been sufficiently lowered to clear the end of the well. In places where a large quantity of dredging has to be done, a stationary dredger with three or four large hopper barges proves generally to be the most economical kind of plant. It has, however, the disadvantage of requiring large capital expenditure, while the dredger and its attendant barges take up an amount of space which is sometimes inconvenient where traffic is large and the navigable width narrow. The principal improvements made in barge-loading dredgers have been the increase in the size of the buckets, in the strength of the dredging gear, in the application of more economical engines for working the machinery, and in the use of frictional gearing for driving the ladder-hoisting gear. It is very important that the main drive be fitted with friction blocks or clutches which shall slip and prevent breakage in the machinery when hidden obstacles causing unusual strain come in the path of the buckets.

Up to the year 1877 dredgers were seldom made with buckets of a capacity exceeding 9 cubic ft., but since that time they have been gradually increased to 14, 16, and 18 cubic ft. capacity, while in the dredger *Melbourne*, constructed by Messrs William Simons & Co. to the design and specification of Messrs Coode, Son, & Matthews about the year 1886, the buckets had a capacity of 22 cubic ft., the dredger being capable of making 37 feet of water. The driving power consisted of two pairs of compound surface condensing engines, each of 250 I.H.P., having cylinders 20 in. and 40 in. in diameter respectively, with a 30-in. stroke, the boiler pressure being 90 ℔ per square inch. The vessel was 200 ft. long by 36 ft. wide and 11 ft. 6 in. deep, and was driven by twin-screw propellers. The gearing was arranged so that either pair of engines could be employed for dredging. The speed under steam was 7 knots, and in free-getting material 800 tons per hour could be dredged with ease. On one occasion the dredger loaded 400 tons in 20 minutes. The speed of the bucket chain was 83 lineal ft. per minute. The draught of the dredger in working trim was 7 ft. forward and 9 ft. aft. The efficiency of the machine, or the net work done in raising materials compared with the power exerted in the cylinders, was about 25 per cent. The dredged material was delivered into barges moored alongside. Contrasting favourably with former experience, the *Melbourne* worked for the first six months without a single breakage. She was fitted with very powerful mooring winches, a detail which is of great importance to ensure efficiency in working.

The *St Austell* (Fig. 1), another powerful barge-loading dredger, 195 ft. long by 35 ft. 6 in. beam by 13 ft. deep, fitted with twin-screw compound surface-condensing propelling engines of 1000 I.H.P., either set of engines being available for dredging, was constructed for H.M. Dockyard, Devonport, by Messrs William Simons & Co. in 1896. This dredger loaded thirty-five 500-ton hopper barges in the week ended 2nd April 1898, dredging 17,500 tons of material in the working time of 29 hours 5 minutes.

An instance of a still larger and more powerful dredger is the *Devolant*, constructed by Messrs William Simons & Co. for Nicolaieff, South Russia. She is a bow well, barge-loading, bucket-ladder dredger. Length 186 ft., breadth, moulded, 36 ft., depth, moulded, 13 ft. The bucket ladder is of sufficient length to dredge 36 ft. below the water-level. The buckets are exceptionally large, each having a capacity of 36 cubic ft., or fully two tons weight of material, giving a lifting capacity of 1890 tons per hour. At the dredging trials 2000 tons of spoil were lifted in one hour with an expenditure of 250 I.H.P. The propelling power is supplied by one pair of compound surface-condensing marine engines of 850 I.H.P., having two cylindrical boilers constructed for a working pressure of 120 ℔ per square inch. Each boiler is capable of supplying steam to either the propelling or the dredging machinery, thus allowing the vessel always to have a boiler in reserve. On the trials a speed of 8½ knots was obtained. The bucket ladder, which weighs over 100 tons, exclusive of dredgings, is raised and lowered by a set of independent engines. For manœuvring, powerful winches driven by independent engines are placed at the bow and stern. The vessel is fitted throughout with electric light, arc lamps being provided above the deck to enable dredging to be carried on at night. Steam steering gear, a repairing shop, a 3-ton crane, and all the latest appliances are installed on board.

The *Majestic*, constructed by Messrs Lobnitz & Co., is a good example of a dredger fitted with their patent rock cutters, as used on the Suez Canal. These rock cutters consist of stamps passing down through the bottom of the dredger, slightly in advance of the bucket chain, and are employed for breaking up rock in front of the bucket ladder so that it may afterwards be raised by the buckets.

In regard to the depth of water which can be made by dredging, it is interesting to note that the dredger *Diver*, constructed by Messrs Hunter & English for Mr Samuel Williams of London, is capable of working in 60 ft. of water. In this vessel an ingenious arrangement was devised by Mr Williams, by which part of the weight of the dredger was balanced while the ladder itself could be drawn up through the bucket well and placed upon the deck, enabling a long ladder to be used with a comparatively short vessel. The *Tilbury* dredger, constructed by the same firm, is able to dredge to a depth of 45 ft. below the surface of the water.

*Hopper Dredgers.*—In places where barge-loading dredgers are inconvenient, owing to confined space and interference with the navigation, and where it is further necessary to curtail capital expenditure, hopper dredgers are convenient and economical. The vessel for this type of dredger is made of sufficient length and floating capacity to contain its own dredgings, which it carries out to the depositing ground as soon as its hopper is full. Considerable time is of course occupied in slipping and recovering moorings and in conveying material to the depositing ground, but these disadvantages are in many instances counterbalanced by the fact that less capital is required for plant and that less room is taken up by the dredger. If the depositing ground is far away, the time available for dredging is much curtailed, but the four-screw hopper dredger constructed by Messrs W. Simons & Co. for Bristol has done good work at the cost of 5d. per ton, including wages, repairs, coals, grease, sundries, and interest on the first cost of the plant, notwithstanding that the material has to be taken 10 miles from the Bristol docks. It can lift 400 tons of stiff clay per hour from a depth of 36 ft. below the water-line, and the power required varies from 120 I.H.P. to 150 I.H.P., according to the nature of the material. The speed is 9 knots, and four propellers were provided, two at the head and two at the stern, to enable the vessel to steam equally well either way, as the river Avon is too narrow to permit her to be turned round.

The largest bucket hopper dredger in the world is *La Puissante* (Fig. 2), constructed by Messrs William Simons & Co. Ltd. for the Suez Canal Company, for the improvement of Port Said roads. It is 275 ft. long by 47 ft. beam by 19 ft. deep. The hopper capacity is 2000 tons, and the draught loaded 16 ft. 5 ins. The maximum dredging depth is 40 ft. and the minimum dredging depth is only limited by the vessel's draught, it being able to cut its own way. The bucket ladder working through the well in the stern weighs, with buckets, 120 tons. The buckets each have a capacity of 30 cubic ft., and raised on trial 1600 tons per hour. The dredger is propelled by two sets of independent triple-expansion surface-condensing engines of a combined indicated horse-power of 1800, working with steam at 160 ℔ pressure, supplied by two mild steel multitubular boilers. Each set of engines is capable of driving the buckets independently at speeds of sixteen and twenty buckets per minute. The bucket ladder is fitted with buffer springs at its upper end to lessen the shock when working in a sea-way. The

dredger can deliver the dredged material either into its own hopper or into barges lying on either side. The vessel attained a speed of 9¾ knots per hour on trial. The coal consumption during six hours steaming trial was 1·66 ℔ per I.H.P. per hour.

*Dredgers fitted with Long Shoot or Shore Delivering Apparatus.*—The first instance of dredgers being fitted with long shoots was in the Suez Canal. The soil in the lakes was very variable, the surface being generally loose mud which lay in some places on sand, but frequently on more or less hard clay. Mr Lavalley employed shoots 230 ft. long, supported on pontoons connected with the hull of the dredger. The sand flowed away with a moderate supply of water to the shoots when they were fixed at an inclination of about 1 in 20, but when the sand was mixed with shells, these formed a coating which prevented the stream of water from washing out the shoot, and even with an inclination of 1 in 10 the material could not be delivered. A pair of endless chains working down the long shoot overcame the difficulty, and also enabled hard clay in lumps to be dealt with. One dredger turned out about 2000 cubic yards of thick clay in 15 hours, and when the clay was not hard it could deliver 150,000 cubic yards in a month for several consecutive months.

A dredger (Fig. 3) constructed by Messrs Hunter & English for reclamation works on Lake Copais in Greece was fitted with delivery belts running on rollers in steel lattice frames on each side of the vessel, supported by masts and ropes. It could deliver 100 cubic metres per hour at 85 ft. from the centre of the dredger, at a cost of 1·82d. per cubic metre for working expenses, with coal at 45s. per ton, including 0·66d. per cubic metre for renewal of belts, upon which the wear and tear was heavy.

Another instance of the successful application of shore-delivery apparatus is that of a dredger for Lake Titicaca, Peru, which was fitted with long shoots on both sides, conveying the dredged material about 100 ft. from the centre of the dredger upon either side. The shoots were supported by shear-legs and ropes, and were supplied with water from a centrifugal pump in the engine-room. This dredger could excavate and deliver 120 cubic yards per hour at a cost of 1·725d. per cubic yard with coal costing 40s. per ton. If coal had been available at the ordinary rate in England of 20s. per ton, the cost of the dredging and delivery would have been 0·826d. per cubic yard for wages, coal, oil, &c., but not including the salary of the superintendent.

An interesting example of a shore-delivering dredger is a light-draught dredger for the Lakes of Alberpera at the mouth of the Ebro in Spain. The conditions laid down for this dredger were that it should float in 18 in. of water and deliver the dredged material at 90 ft. from the centre of its own hull. In order to meet the latter requirement, the vessel was made of steel plates ⅛ in. thick, and longitudinal girders ran from end to end of the vessel, the upward strain of flotation being conveyed to them from the skin plating by transverse bulkheads at short intervals. The dredger was 94 ft. long, 25 ft. wide, and 3 ft. deep, and the height of the top tumbler above the water was 25 ft. When completed it drew 17 in. of water. The dredgings were delivered by the buckets upon an endless belt, driven from the main compound surface condensing engine, which ran over pulleys supported upon a steel lattice girder, the outer end of which rested upon an independent pontoon. This belt delivered the dredgings at 90 ft. from the centre of the dredger round an arc of 180 degrees. The dredger delivered 125 cubic yards per hour of compact clay at a cost of 1·16d. per cubic yard or 0·86d. per ton for wages, coal, and stores.

Another method of delivering dredgings is that of pneumatic delivery, introduced by Mr F. E. Duckham, of the Millwall Dock Company, by which the dredgings are delivered into cylindrical tanks in the dredger, closed by air-tight doors, and are expelled by compressed air either into the sea or through long pipes on to the land. The Millwall Dock dredger is 113 ft. long, with a beam of 17 ft. and a depth of 12 ft. The draught loaded is 8 ft. It contains two cylindrical tanks, having a combined capacity of 240 cubic yds., and is fitted with compound engines of about 200 I.H.P., with a 20-in. air-compressing cylinder. The discharge pipe is 15 in. diameter by 150 yds. long. The nozzles of the air-injection pipes must not be too small, otherwise the compressed air, instead of driving out the material, simply pierces holes through it and escapes through the discharging pipe, carrying with it all the liquid and thin material in the tanks. The cost of working the Millwall Dock dredger is given by Mr Duckham at 1·75d. per cubic yard of mud lifted, conveyed, and deposited on land 450 ft. from the water-side, for working expenses only. This dredger is believed to be the first one constructed with a traversing ladder, as suggested by the late Captain Gibson when dock-master of the Millbank Docks.

*Sand-Pump Dredgers.*—Perhaps the most important development which has taken place in dredging during recent years has been the employment of sand-pump dredgers, which are very useful for removing sandy bars where the particular object is to remove quickly a large quantity of sand or other soft material. They are, however, apt to make large holes, and are therefore not fitted for positions where it is necessary to finish off the dredging work to a uniform flat bottom, for which purpose bucket dredgers are better adapted. Pump dredgers are, however, admirable and economical machines for carrying out the work for which they are specially suited.

In a discussion upon Mr J. J. Webster's paper upon "Dredging Appliances" at the Institution of Civil Engineers in 1886, Sir John Coode stated that he had first seen sand-pump dredgers at the mouth of the Maas in Holland. The centrifugal pump was placed against the bulkheads in the after part of the vessel, and the sand and water were delivered into a horizontal breeches-piece leading into two pipes running along the full length of the hopper. The difficulty in preventing the sand from running overboard was entirely obviated by its being propelled by the pump through these pipes, the bottoms of which were perforated by a series of holes. In addition, there were a few small flap-doors fixed at intervals, by means of which the men were able to regulate the discharge. On being tested, the craft pumped into this hopper 400 tons of sand in 22 minutes. The coamings round the well of the hoppers were constructed with a dip, and when the hopper was full the water ran over in a steady stream on either side. The proportion of sand delivered into the hopper was about 20 per cent. of the total capacity of the pump. The dredger was constructed by Messrs Smit of Kinderdijk, near Rotterdam.

In the same discussion Mr A. A. Langley, then engineer to the Great Eastern Railway Company, gave particulars of a sand pump upon the Bazin system, which had been used successfully at Lowestoft. The boat was 60 ft. long by 20 ft. wide, and the pump was 2 ft. in diameter, with a two-bladed disc. The discharge pipe was 12 in. in diameter. The pump raised 400 tons of sand, gravel, and stones per hour as a maximum quantity, the average quantity being about 200 tons per hour. The depth dredged was from 7 ft. to 25 ft. The pump was driven by a double-cylinder engine, having cylinders of 9 in. diameter by 10 in. stroke, and making 120 revolutions per minute. An important addition was introduced by Mr Ball in fitting the working faces of the pump with indiarubber, which was very successful and largely reduced the wear and tear. The cost of the dredging at Lowestoft was given by Mr Langley at 2d. per ton, including delivery two miles out at sea. The quantity dredged was about 200,000 tons per annum.

One of the earliest applications of pumps for dredging, made by Mr Woodford, consisted of a horizontal disc with two or more arms working in a case somewhat similar to the ordinary centrifugal pump. The disc was keyed to a vertical shaft which was driven from above by means of belts or other gear coupled to an ordinary portable engine. The pump within rested on the ground; the suction pipe was so arranged that water was drawn in with the sand or mud, the proportions being regulated to suit the quality of the material. The discharge pipe was rectangular and carried a vertical shaft, the whole apparatus being adjustable to suit different depths of water. This arrangement was very effective, and has been used on many works. Burt and Freeman's sand pump, a modification of the Woodford pump, was used in the construction of the Amsterdam Ship Canal, for which it was designed. The excavations from the canal had to be deposited on the banks some distance away from the dredgers, and after being raised by the ordinary bucket dredger, instead of being discharged into barges, they were led into a vertical chamber on the top side of the pump, suitable arrangements being made for regulating the delivery. The pump was 3½ ft. in diameter, and made about 230 revolutions per minute. It drew up the water on the bottom side which mixed with the descending mud on the top side, and the two were discharged into a pipe 15 in. in diameter. The discharge pipe was a special feature of this work, and consisted of a series of wooden pipes jointed together with leathern hinges and floated on buoys from the dredger to the bank. In some cases this pipe was 300 yds. long, and discharged the material 8 ft. above the water-level. Each dredger and pump was capable of discharging an average of 1500 cubic yds. per day of 12 hours. Schmidt's sand pump is claimed to be an improvement on the Burt and Freeman pump. It consists of a revolving wheel 6 ft. in diameter, with cutters revolving under a hood which just allows the water to pass underneath. To the top side of the hood a 20-in. suction pipe of an ordinary centrifugal pump is attached. The pump is driven by two 16-in. by 20-in. cylinders, at 134 revolutions per minute, and the cutter by two 12-in. by 12-in. cylinders, working at 120 revolutions per minute, the boiler pres-

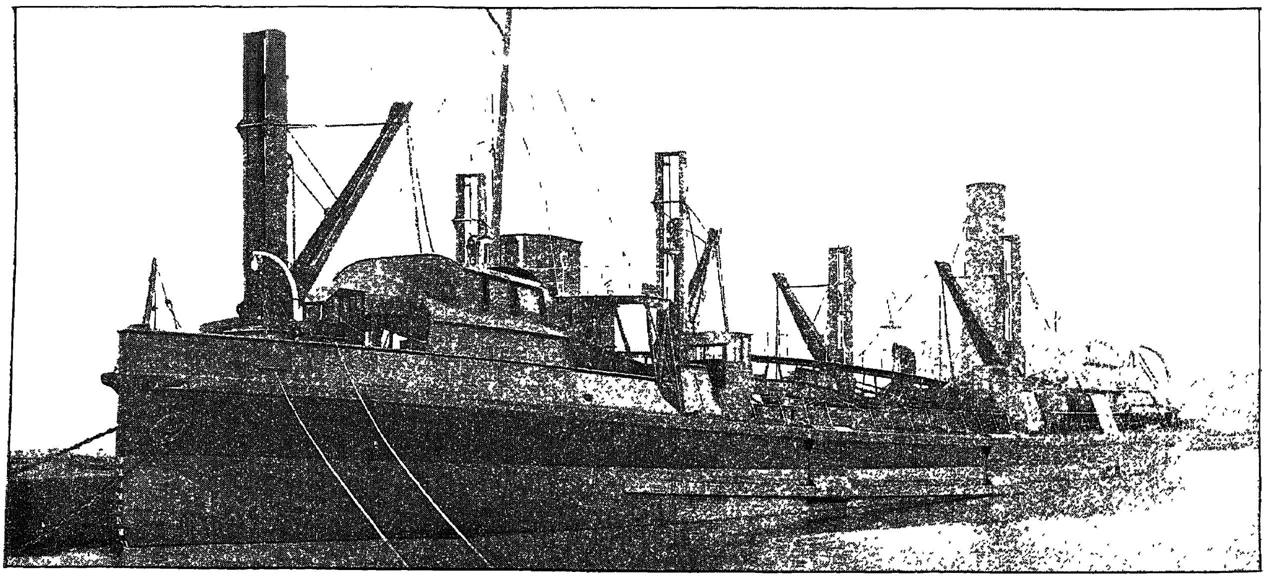

Fig. 6.

DREDGING.

sure being 95 lb per square in. This apparatus is capable of excavating sticky blue clayey mud, and will deliver the material at 500 to 650 yds. distance. The best results are obtained when the mixture of mud and water is as 1 to 6·5. The average quantity excavated per diem by the apparatus is 1300 cubic yds., the maximum quantity being 2500 cubic yds.

Kennard's sand pump is entirely different from the pumps already described, and is a direct application of the ordinary lift pump. A wrought-iron box has a suction pipe fitted at the bottom rising about half-way up the inside of the box; on the top of the box is fitted the actual pump and the flat valves. The apparatus was lowered by chains, and the pump worked from above. As soon as the box was filled with sand it was raised, the catches holding up the bottom were released, and the contents discharged into a punt.

Sand-pump dredgers, designed and arranged by Mr Darnton Hatton, were extensively used on the Amsterdam Ship Canal. A centrifugal pump with a fan 4 ft. in diameter was employed, the suction and delivery pipes, each 18 in. in diameter, being attached to an open wrought-iron framework. The machine was suspended between guides fixed to the end of the vessel, which was fitted with tackle for raising, lowering, and adjusting the machine. The vessel was fitted with a steam-engine and boiler for working and manipulating the pumps and the heavy side chains for the guidance of the dredger. The engine was 70 horse-power, and the total cost of one dredger was £8000. The number of hands required for working this sand-pump dredger was one captain, one engineer, one stoker, and four sailors. Each machine was capable of raising about 1300 tons of material per day, the engines working at 60 and the pump at 180 revolutions per minute. The sand was delivered into barges alongside the dredger. The cost of raising the material and depositing it in barges was about 1d. per ton when the sand pumps were working, but upon the year's work the cost was 2·4d. per cubic yd. for working expenses and repairs, and 1·24d. per cubic yd. for interest and depreciation at 10 per cent. upon the cost of the plant, making a total cost for dredging of 3·64d. per cubic yd. The cost for transport was 3·588d. per cubic yd., making a total cost for dredging and transport of 7·234d. per cubic yd. Dredging and transport on the same works by an ordinary bucket dredger and barges cost 8·328d. per cubic yd.

Two of the largest and most successful instances of sand-pump dredgers are the *Branker* and the *G. B. Crow*, belonging to the Mersey Dock and Harbour Board. Mr A. G. Lyster gave particulars of the work done by these dredgers in a paper read before the Engineering Congress in 1899. They are each 320 ft. long, 47 ft. wide, and 20·5 ft. deep, the draught loaded being 16 ft. They are fitted with 2 centrifugal pumps, each 6 ft. in diameter, with 36 in. suction and delivery pipes, united into a 45-in. diameter pipe, hung by a ball and socket joint in a trunnion, so as to work safely in a sea-way when the waves are 10 ft. high. The suction pipe is 76 ft. long, and will dredge in 53 ft. of water. The 8 hoppers hold 3000 tons, equivalent when solid to 2000 cubic yds.; they can be filled in three-quarters of an hour and discharged in five minutes. Mr Lyster stated that up to May 1899 the quantity removed from bar and main-channel shoals amounted to 41,240,360 tons, giving a width of channel of 1500 ft. through the bar, with a minimum depth of 27 ft. The cost of dredging on the bar by the *G. B. Crow* during 1898, when 4,309,350 tons of material were removed, was 0·61d. per ton for wages, supplies, and repairs. These figures include all direct working costs and a proportion of the charge for actual superintendence, but no allowance for interest on capital cost or for depreciation. On an average, 20 per cent. of the sand and mud that are raised escapes over the side of the vessel. Mr Lyster has, however, to a considerable extent overcome this difficulty by a special arrangement added to the hoppers. (See *Proc. Inst. C. E.* vol. cxxxviii.)

Another powerful and successful sand-pump dredger is the twin-screw dredger *Kate* (see Fig. 4), built in 1897 by Messrs William Simons & Co. Limited for the East London Harbour Board, South Africa. Its dimensions are: length 200 ft., breadth 39 ft., depth 14 ft. 6 in., hopper capacity 1000 tons. The pumping arrangements for filling the hopper with sand or discharging overboard consist of two centrifugal pumps, each driven from one of the propelling engines. The suction pipes are each 27 in. in diameter, and are so arranged that they may be used for pumping either forward or aft, as the state of the weather may require. Four steam cranes are provided for manipulating the suction pipes. Owing to the exceptional weather with which the vessel has to contend, special precautions were taken in designing the attachments of the suction pipes to the vessel. The attachment is above deck, and consists of a series of joints, which give a perfectly free and universal movement to the upper ends of the pipes. The joints, on each side of the vessel, are attached to a carriage, which is traversed laterally by hydraulic gear. By this means the pipes are pushed out well clear of the vessel's sides when pumping, and brought inboard when not at work. Hydraulic cushioning cylinders are provided to give any required resistance to the fore and aft movements of the pipes. When the vessel arrived at East London on the 18th July 1897 there was a depth of 14 ft. on the bar at high water. On 10th October, scarcely three months afterwards, there was a depth of 20 ft. on the bar at low water. Working 22 days in rough weather during the month of November 1898, the *Kate* raised and deposited $2\frac{1}{2}$ miles at sea 60,000 tons of dredgings. Her best day's work (12 hours) was on the 7th November, when she dredged and deposited 6440 tons.

A large quantity of sand-pump dredging has been carried out at Boulogne and Calais by steam hopper pump dredgers, workable when the head waves are not more than 3 ft. high and the cross waves not more than $1\frac{1}{2}$ ft. high. The dredgings are taken 2 miles to sea, and the price for dredging and depositing from 800,000 to 900,000 cubic metres in 5 or 6 years was 7·25d. per cubic yard. The contractor offered to do the work at 4·625d. per cubic yard on condition of being allowed to work either at Calais or Boulogne, as the weather might permit. Sand-pump dredging has also been extensively carried out at the mouth of the ports of Amsterdam, Rotterdam, and on the north coast of France by sand dredgers constructed by Messrs L. Smit & Son and G. & K. Smit. The largest dredger, the *Amsterdam*, is 141 ft. by 27 ft. by 10 ft. 8 in., and has engines of 190 I.H.P. The hopper capacity is 10,600 cubic ft., and the vessel can carry 600 tons of dredgings. The pump fan is 6 ft. 3 in. in diameter by 10 in. wide, the plates being of wrought-iron, and makes 130 revolutions a minute. The pump can raise 230 cubic ft. a minute from a depth of 33 ft., which, taking the proportion of 1 of sand to 7 of water, gives a delivery of 29 cubic ft. of sand per minute. The hopper, containing 10,600 cubic ft., was under favourable circumstances filled in 40 minutes. The vessels are excellent sea boats.

*Combined Bucket-Ladder and Sand-Pump Dredgers.*—Recently bucket ladders and sand pumps have both been fitted to the same dredger. A successful example of this practice is furnished by the hopper dredger *Percy Sanderson* (see Fig. 5), constructed under the direction of Sir Charles L. Hartley, engineer of the Danube Commission for the deepening of the river Danube and the Sulina bar. This dredger is 220 ft. by 40 ft. by 17 ft. 2 in., and has a hopper capacity for 1250 tons of dredgings. The buckets have each a capacity of 25 cubic ft., and are able to raise 1000 tons of ordinary material per hour. The suction pump, which is driven by an independent set of triple-expansion engines, is capable of raising 700 tons of sand per hour, and of dredging to a depth of 35 ft. below the water-line. The lower end of the suction pipe is controlled by special steam appliances by which the pipe can be brought entirely inboard. The *Percy Sanderson* raises and deposits on an average 5000 tons of material per day.

*Hopper Barges.*—Where dredging operations on a large scale are being carried out, steam hopper barges are generally employed. Good examples of these vessels are the two steam hopper barges built for the Conservators of the river Thames in 1898. Their dimensions are: length 190 ft., breadth 30 ft., depth 15 ft. 3 in., hopper capacity 900 tons. They are propelled by a set of triple-expansion engines of 1200 I.H.P., with two return tubular boilers having a working pressure of 160 lb. Special appliances are provided to work the hopper doors by steam power from independent engines placed at the forward end of the hopper. A steam windlass is provided forward and a steam capstan aft. The vessels are fitted with cabins for the officers and crew. On their trial trip, the hoppers having their full load, a speed of 11 knots was attained, the coal consumption being 1·44 lb per I.H.P.

*Grabs.*—Various kinds of apparatus have been designed in the shape of grabs or buckets for dredging purposes. These are usually worked by a steam crane, which lets the open grab down to the surface of the ground to be excavated and then closes it by a chain which forces the tines into the ground; the grab is then raised by the crane, which deposits the contents either into the hopper of the vessel upon which the crane is fixed or into another barge.

The Priestman grab has perhaps been more extensively used than any other apparatus of this sort. It is very useful for excavating mud, gravel, and soft sand, but is less effective with hard sand or stiff clay, which is a general defect in this class of dredger. It is

also capable of lifting large loose pieces of rock weighing from one to two tons. A dredger of this type, with grab holding one ton of mud, dredged during six days, in 19 ft. of water, an average of 52½ tons and a maximum of 68½ tons per hour, and during 12 days, in 16 ft. of water, an average of 48 tons and a maximum of 58 tons per hour, at a cost of 1·63d. per ton, excluding interest on the capital and depreciation. The largest dredger to which this apparatus has been applied is the grab bucket hopper dredger *Miles K. Burton* (see Fig. 6), belonging to the Mersey Docks and Harbour Board. It is equipped with five grabs on Morgan's patent system, which is a modification of Priestman's, the grabs being worked by five hydraulic cranes. It raised and deposited, 12 to 15 miles out at sea, 11 loads of about 1450 tons each with a double shift of hands, at a cost of about 1·5d. per cubic yard of spoil, including the working expenses for wages of crew, fuel, and stores. Mr Marillier of Hull has stated that "the efficiency of these grabs is not at all dependent upon the force of the blow in falling for the penetration and grip in the material, as they do their work very satisfactorily even when lowered quite gently on to the material to be cut out, the jaws being so framed as to draw down and penetrate the material as soon as the upward strain is put on the lifting chain. Even in hard material the jaws penetrate so thoroughly as to cause the bucket to be well filled. The grab is found to work successfully in excavating hard clay from its natural bed on dry land." It is claimed on behalf of grabs that they lift a smaller proportion of water than any other class of dredger.

Wild's single chain half-tine grab works entirely with a single chain, and has been found very useful in excavating the cylinders in Castries harbour. Upon experimenting with an ordinary grab a rather curious condition of things was observed with respect to sinking. On penetrating the soil to a certain depth the ground was found, as it were, nested, and nothing would induce the grab to sink lower. Mr Matthews suggested that an additional set of external tines might possibly get over this difficulty. A new grab having been made with this modification, and also with a large increase of weight—all the parts being steel—it descended to any required depth with ease, the outside tines loosening the ground effectually, whilst the inside bucket or tines picked up the material.

*Miscellaneous Appliances.*—Under this head may be classed several machines or appliances which perhaps can hardly be called dredgers, although they are used for cleansing and deepening rivers and harbours.

Kingsfoot's dredger, used for cleansing the river Stour, consisted of a boat with a broad rake fitted to the bow, capable of adjustment to different depths. At the sides of the boat were hinged two wings of the same depth as the rake and in a line with it. When the rake was dropped to the bottom of the river and the wings extended to the side, they formed a sort of temporary dam, and the water began to rise gradually. As soon as a sufficient head was raised, varying from 6 to 12 in., the whole machine was driven forward by the pressure, and the rake carried the mud along with it. A progress of about 3 miles an hour was made in this manner, and to prevent the accumulation of the dredgings, operations were begun at the mouth of the river and carried on backwards. The apparatus was very effective and the river was cleansed thoroughly, but the distance travelled by the dredger must have been great.

In 1876 J. J. Rietschoten designed a "propeller dredger" for removing the shoals of the river Maas. It consisted of an old gunboat fitted with a pair of trussed beams—one at each side—each of which carried a steel shaft and was capable of being lowered or raised by means of a crab. An ordinary propeller 3 ft. 6 in. in diameter was fixed to the lower end of each shaft, and driven by bevel-gear from a cross shaft which derived its motion by belting from the fly-wheel of a 12 H.P. portable engine. The propellers were lowered until they nearly reached the shoals, and were then worked at 150 revolutions per minute. This operation scoured away the shoal effectively, for in about 40 minutes it had been lowered about 3 ft. for a space 150 yards long by 8 yards wide.

Mr Lavalley in 1877 designed an arrangement for the harbour of Dunkirk to overcome the difficulty of working an ordinary bucket-ladder dredger when there is even a small swell. A pump injects water into the sand down a pipe terminating in three nozzles to stir up the sand, and another centrifugal pump draws up the mixed sand and water and discharges it into a hopper, the pumps and all machinery being on board the hopper. To allow for the rising and falling of the vessel—either by the action of the tide or by the swell—the ends of the pipes are made flexible. The hopper has a capacity of 190 cubic yards, and is propelled and the pumps worked by an engine of 150 I.H.P. From 50 to 80 cubic yards per hour can be raised by this dredger.

The "Aquamotrice," designed by Mr Popie and used on the Garonne at Agen, appears to be a modification of the old bag and spoon arrangement. A flat-bottomed boat 51½ ft. long by 6½ ft. wide was fitted at the bow with paddles, which were actuated by the tide. Connected with the paddles was a long chain, passing over a pulley on uprights and under a roller, and a beam was attached to the chain 14 ft. 8 in. long, passing through a hole in the deck. At the end of the beam was an iron scoop 2 ft. wide and 2 ft. 6 in. deep. When the tide was strong enough it drew the scoop along by means of the paddles and chains, and the scoop when filled was discharged by means of a lever opening it. About 65 cubic yards of gravel can be raised by the apparatus in 12 hours. When the tide failed, the apparatus was worked by men.

The Danube Steam Navigation Co. removed the shingle in the shallow parts of the river by means of a triangular rake with wrought-iron sides 18 ft. long, and fitted with 34 teeth of chilled cast-iron 12 in. deep. This rake was hung from the bow of a steamer 180 ft. long by 21 ft. beam, and dragged across the shallows, increasing the depth of water in one instance from 5 ft. 6 in. to 9 ft., after passing over the bank 355 times.

A combination of a harrow and high-pressure water jets, arranged by Mr Tydeman, was found very efficacious in removing a large quantity of mud which accumulated in the Tilbury Dock basin, which has an area of about 17 acres, with a depth of 26 ft. at low-water spring tides. In the first instance chain harrows merely were used, but the addition of the water jets added materially to the success of the operation. The system accomplished in six tides more than was done in twelve tides without their aid. The water jets worked at about 80 ℔ pressure per square in., attaining an effective pressure of about 60 ℔ per square in. at the bottom of the dock.

Ives's excavator consists of a long weighted spear, with a sort of large spade at the end of it. The spade is hinged at the top, and is capable of being turned at right angles to the spear by a chain attached to the end of the spear. The spade is driven into the ground and, after releasing the catch which holds it in position during its descent, it is drawn up at right angles to the spear by the chain, carrying the material along with it. Milroy's excavator is similar, but instead of having only one spade it generally has eight, united to the periphery of an octagonal iron frame fixed to a central vertical rod. When these eight spades are drawn up by means of chains, they form one flat table or tray at right angles to the central rod. In operation the spades hang vertically, and are dropped into the material to be excavated; the chains are then drawn up, and the table thus formed holds the material on the top, which is lifted and discharged by releasing the spade. This apparatus has been extensively used both in this country and in India for excavating in bridge cylinders.

The clam-shell dredger consists of two hinged buckets, which, when closed, form one semi-cylindrical bucket. The buckets are held open by chains attached to the top of a crosshead, and the machine is dropped on to the top of the material to be dredged. The chains holding the buckets open are then released, while the spears are held firmly in position, the buckets being closed by another chain. Bull's dredger, Gatmell's excavator, and Fouracres's dredger are modifications with improvements of the clam-shell dredger, and have all been used successfully upon various works.

Bruce and Batho's dredger, when closed, is of hemispherical form, the bucket being composed of three or four blades. It can be worked either by a single chain or by means of a spear, the latter being generally used for stiff material. The advantage of this form of dredger bucket is that the steel points of the blades are well adapted for penetrating hard material. Messrs Bruce and Batho have also designed a novel dredger consisting of one of these buckets, but worked entirely by hydraulic power. This was made for working on the Tyne. The excavator or dredger is fixed to the end of a beam which is actuated by two hydraulic cylinders, one being used for raising the bucket and the other for lowering it; the hydraulic power is supplied by the pumps in the engine-room. The novelty in the design is the ingenious way in which the lever in ascending draws the shoot under the bucket to receive its contents, and draws it away again as the bucket descends. The hydraulic cylinder at the end of the beam is carried on gimballs to allow for the irregularities of the surface being dredged. The hydraulic pressure is 700 ℔ per square in., and the pumps are used in connexion with a steam accumulator.

An unloading apparatus was designed by Mr A. Manning for the East and West India Dock Company for unloading the dredged materials out of barges and delivering it on the marsh at the back of the bank of the river Thames at Crossness, Kent. A stage constructed of wooden piles commanded a series of barge beds, the unloading dredger running from end to end of the stage, lifting and delivering the materials on to the marsh behind the river wall at the cost of 1d. per cubic yard.

*Dredging combined with Blasting.*—In the *Encyclopædia Britannica*, vol. vii. p. 466, a description was given of blasting and dredging upon the river Tees. This may profitably be supplemented by an account of similar operations in Blyth harbour (cp. *Proc. Inst. C. E.* vol. lxxxi. p. 302). Here it became necessary to provide extensive deep-water berths, and the site determined upon was on

the south side of Blyth, about a mile from the harbour entrance. The bottom of the river at this place was formed of a large patch of rock, which had long been a serious obstruction to dredging operations, and which it was necessary to remove in order to provide the required depth. The rock was 700 ft. long by 139 ft. 6 in. at its widest part, a width of 85 ft. being dry at low water of spring tides. The material consisted of yellow sandstone, rocky shale, and clay, lying in horizontal beds; there was also a considerable proportion of very hard quartzite in the form of large boulders and irregular beds. The shoal was of very irregular character and the clay layers were the worst feature, as they rendered effective blasting difficult.

The means employed were, first, boring and blasting; secondly, dredging. The boring was effected by hand labour, from rafts 25 ft. by 13 ft., made of yellow pine logs decked over with planking. The bore-holes were $2\frac{7}{8}$ in. diameter. The drills were chisel-pointed, $2\frac{3}{4}$ in. broad, the shanks being $1\frac{1}{4}$ in. diameter. Boring tubes 3 in. diameter were firmly driven into the ground after the raft was moored, and drills were worked within them. The tubes prevented the sand from getting into the bore-holes, and enabled cartridges to be rammed home without the aid of a diver. Four men were required at each drill. The average speed of boring was about 3 lin. ft. per hour, and the cost for labour was 1s. per lin. ft. At first the work was carried on as tide-work, but afterwards by day-work irrespective of the tide, which was found to be cheaper. It was originally intended to do the operation in one lift, but the dredger was not powerful enough, so the operation was effected in two lifts, the first 9 ft. deep and the second to the finished depth of 15 ft. below water at spring tides.

The bore-holes were arranged in diagonal squares of 6 ft. 3 in., the upper series being bored to 9 ft. 10 in. and the lower to 15 ft. 6 in. below low water. The blasting charges were contained in water-tight tin cases 2 in. diameter, closed at the top with wood plugs 2 in. deep. Bickford's double-coated gutta-percha fuzes and Nobel's detonators were used, and there were few misfires, except in frosty weather, when the dynamite was liable to burn. No tamping material was employed. After blasting, the material was removed by dredging, the greater portion being loaded into hopper barges and deposited about three miles from the site of the works. The dredger employed belonged to the harbour authorities, and was 100 ft. long by 25 ft. beam by 10 ft. deep. Thirty-two buckets and claws, capable of dredging 90 tons per hour of soft sand and mud from a depth of 23 ft., excavated only 6 tons of rock per hour. The buckets had a capacity of 2·82 ft. and weighed 5 cwt. The hoppers were each of 120 tons capacity. The Priestman grab was occasionally used, and was found effective for lifting large loose pieces of rock up to 2 tons in weight. When the blocks exceeded this weight, they were lifted by a floating steam crane in conjunction with a diver. Dredging was carried on both by day and night, two crews working alternately in twelve-hour shifts. Small ridges and patches about 12 in. high, missed by the dredger, were removed by a diver with pick and bar. In this way 24,500 cubic yds. of rock, with a large quantity of mud and sand, were removed; 4500 $2\frac{7}{8}$ in. holes were fired; and after deducting the gunpowder which was not efficacious, 11,820 ℔ of explosives, principally nitro-glycerine compounds, were used, being 0·482 ℔ of explosives per cubic yard. The cost of the explosives per cubic yard was 1s. 4d., of boring 1s. 9d. per cubic yard, and of dredging 3s. per cubic yard, including repairs, but nothing for the use of plant. The whole cost worked out to 6s. 1d. per cubic yard on the average.

*Dredging in the River Scheldt below Antwerp.*—This dredging took place at Krankeloon and the Belgian Sluis under the direction of Mr L. Van Gansberghe. At Melsele there is a pronounced bend in the river, causing a bar at the Pass of Port Philip, and just below the Pass of Lillo there is a cross-over in the current, making a neutral point and forming a shoal. After dredging to 8 metres (26·24 ft.) below low tide, in clay containing stone and ferruginous matter, a sandstone formation was encountered, which was very compact and very difficult to raise. A suction dredger being unsuited to the work, a bucket-ladder dredger was employed. The dredging was commenced at Krankeloon in September 1894 and continued to the end of 1897. A depth of six metres (19·68 ft.) was excavated at first, but was afterwards increased to eight metres (26·24 ft.). The place of deposit was at first on lands acquired by the State, 2·17 miles above Krankeloon, and placed at the disposal of the contractor. The dredgings excavated by the bucket-ladder dredger were deposited in scows, which were towed to the front of the deposit ground and discharged by a suction pump fixed in a special boat, moored close to the bank of the river. The material brought by the suction dredger in its own hull was discharged by a plant fixed upon the dredger itself. In both instances the material was deposited at a distance of 1640 ft. from the river, the spoil bank varying in depth from 6·56 ft. to 22·96 ft. The water thrown out behind the dyke with the excavated material returned to the river, after settlement, by a special discharge lock built under the dyke. Since 1896 the material was delivered into an abandoned pass by means of barges with bottom hopper doors or by the suction dredger. One suction dredger and three bucket-ladder dredgers were employed upon the work, and a vessel called *Scheldt I.* used for discharging the material from the scows. Four tug-boats and twenty scows were also employed.

The largest dredger, *Scheldt III.*, was 147·63 ft. long by 22·96 ft. wide by 10·98 ft. deep, and had buckets of 21·18 cubic ft. capacity. The output per hour was 10,594 cubic ft. This dredger had also a complete installation as a suction dredger, the suction pipe being 2 ft. diameter. The fan of the centrifugal pump was 5·25 ft. diameter, and was driven by the motor of the bucket ladder. The three bucket dredgers worked with head to the ebb tide. They could also work with head to the flood tide, but it took so long a time to turn them about that it was impracticable. The work was for from 13 to 14 hours a day on the ebb tide. The effective daily excavation averaged 4839 cubic yds. Each dredger was fitted with six anchors. The excavated cut was 164 ft. wide by 6·56 ft. deep. *Scheldt III.* was capable of lifting a mass 9·84 ft. thick. The suction dredger *Scheldt II.* was of the multiple type, and is stated to be unique in construction. It can discharge material from a scow alongside, fill its own hopper with excavations, discharge its own load upon the bank or into a scow by different pipes provided for the purpose, and discharge its own load through hopper doors. The machinery is driven by a triple-expansion engine of 300 I.H.P. working the propeller by a clutch. Owing to the rise and fall in the tide of 23 ft., the suction pipe is fitted with spherical joints and a telescopic arrangement. The vessel is 157·5 ft. by 28·2 ft. by 12·8 ft. The diameter of the pump is 5·25 ft. The wings of the pump are curved, the surface being in the form of a cylinder parallel to the axis of rotation, the directrix of which is an arc of a circle of 2·62 ft. radius with the straight part beyond. The suction and discharge pipes are 2 ft. diameter. A centrifugal pump is provided for throwing water into the scows to liquefy the material during discharge. The dredger, which is fitted with electric lights for work at night, is held by two anchors, to prevent lurching backwards and forwards; it can work on the flood as well as on the ebb tide, and can excavate to a depth of 42·65 ft., the output depending upon the nature of the material. With good material it can fill its tanks in thirty minutes. To empty the tanks by suction and discharge upon the bank over the dyke takes about fifty minutes, depending upon the height and distance to which the material requires to be delivered. The daily work has averaged eighteen hours, ten trips being made when the distance from the dredging ground to the point of delivery is about one mile. When the dredged material is discharged into the *Scheldt*, a quantity of 5886 cubic yards has been raised and deposited in a day, the mean quantity being 4700 cubic yards. When the distance of transportation is increased to $2\frac{1}{2}$ miles, six voyages were made in a day, and the day's work amounted to 3530 cubic yards.

The work was let to the contractor at the following prices:—

| | |
|---|---|
| For excavation, transportation, and deposit 2·17 miles in Polder of Borgerwoort . . . . . | 4·5d. per cubic yd. |
| For excavation, transportation, and discharge in disused parts of the Scheldt . . . . . | 2·0d. ,, ,, |
| For excavation and leading into a scow | 1·2d. ,, ,, |
| the transportation by water per kilometre being . . . . | ·15d. ,, ,, |
| For discharge of scows in the Scheldt . | ·55d. ,, ,, |
| For dredging into scows and delivering on to the embankments in Polder of Borgerwoort . . . . | 2·0d. ,, ,, |
| The extra price for dredging heaps of stone found in the bed of the river was . . . . . . | 1·75d. ,, ,, |

The output and cost of dredging and delivering were as follows from the different dredgers:—

| | |
|---|---|
| *Geisendam*—For excavating and transporting 6·2 miles and discharging into the Scheldt, requiring a tug and 5 scows. The work done was 1765 cubic yds. per diem | 5·2d. per cubic yd. |
| *Elizabeth*—For transporting 1·55 miles and discharging into Scheldt with tug and 3 scows, 3793 cubic yds. per diem | 2·4d. ,, ,, |
| *Scheldt III.*—Transporting 2·17 miles and discharging upon lands of Polder 1312 ft. behind the dyke, 1 tug and 5 scows, and using a suction boat for discharging over the dyke, 4839 cubic yds. per diem. | 4·8d. ,, ,, |
| *Scheldt II.*—This suction dredger excavated, transported 2·48 miles, and delivered upon the Polder 2943 cubic yds. per diem | 4·8d. ,, ,, |

The above prices are those paid to the contractor. It is estimated that the cost was about 2·5d. delivered on the bank and ·15d. delivered into the Scheldt.

*River Garonne.*—The cost of dredging upon this river was given in a paper by M. H. Desprez of Paris. The mean cost of dredging, transporting, and placing upon the bank 14,271 cubic ft. was 4·625d. per cubic yd., made up as under:—

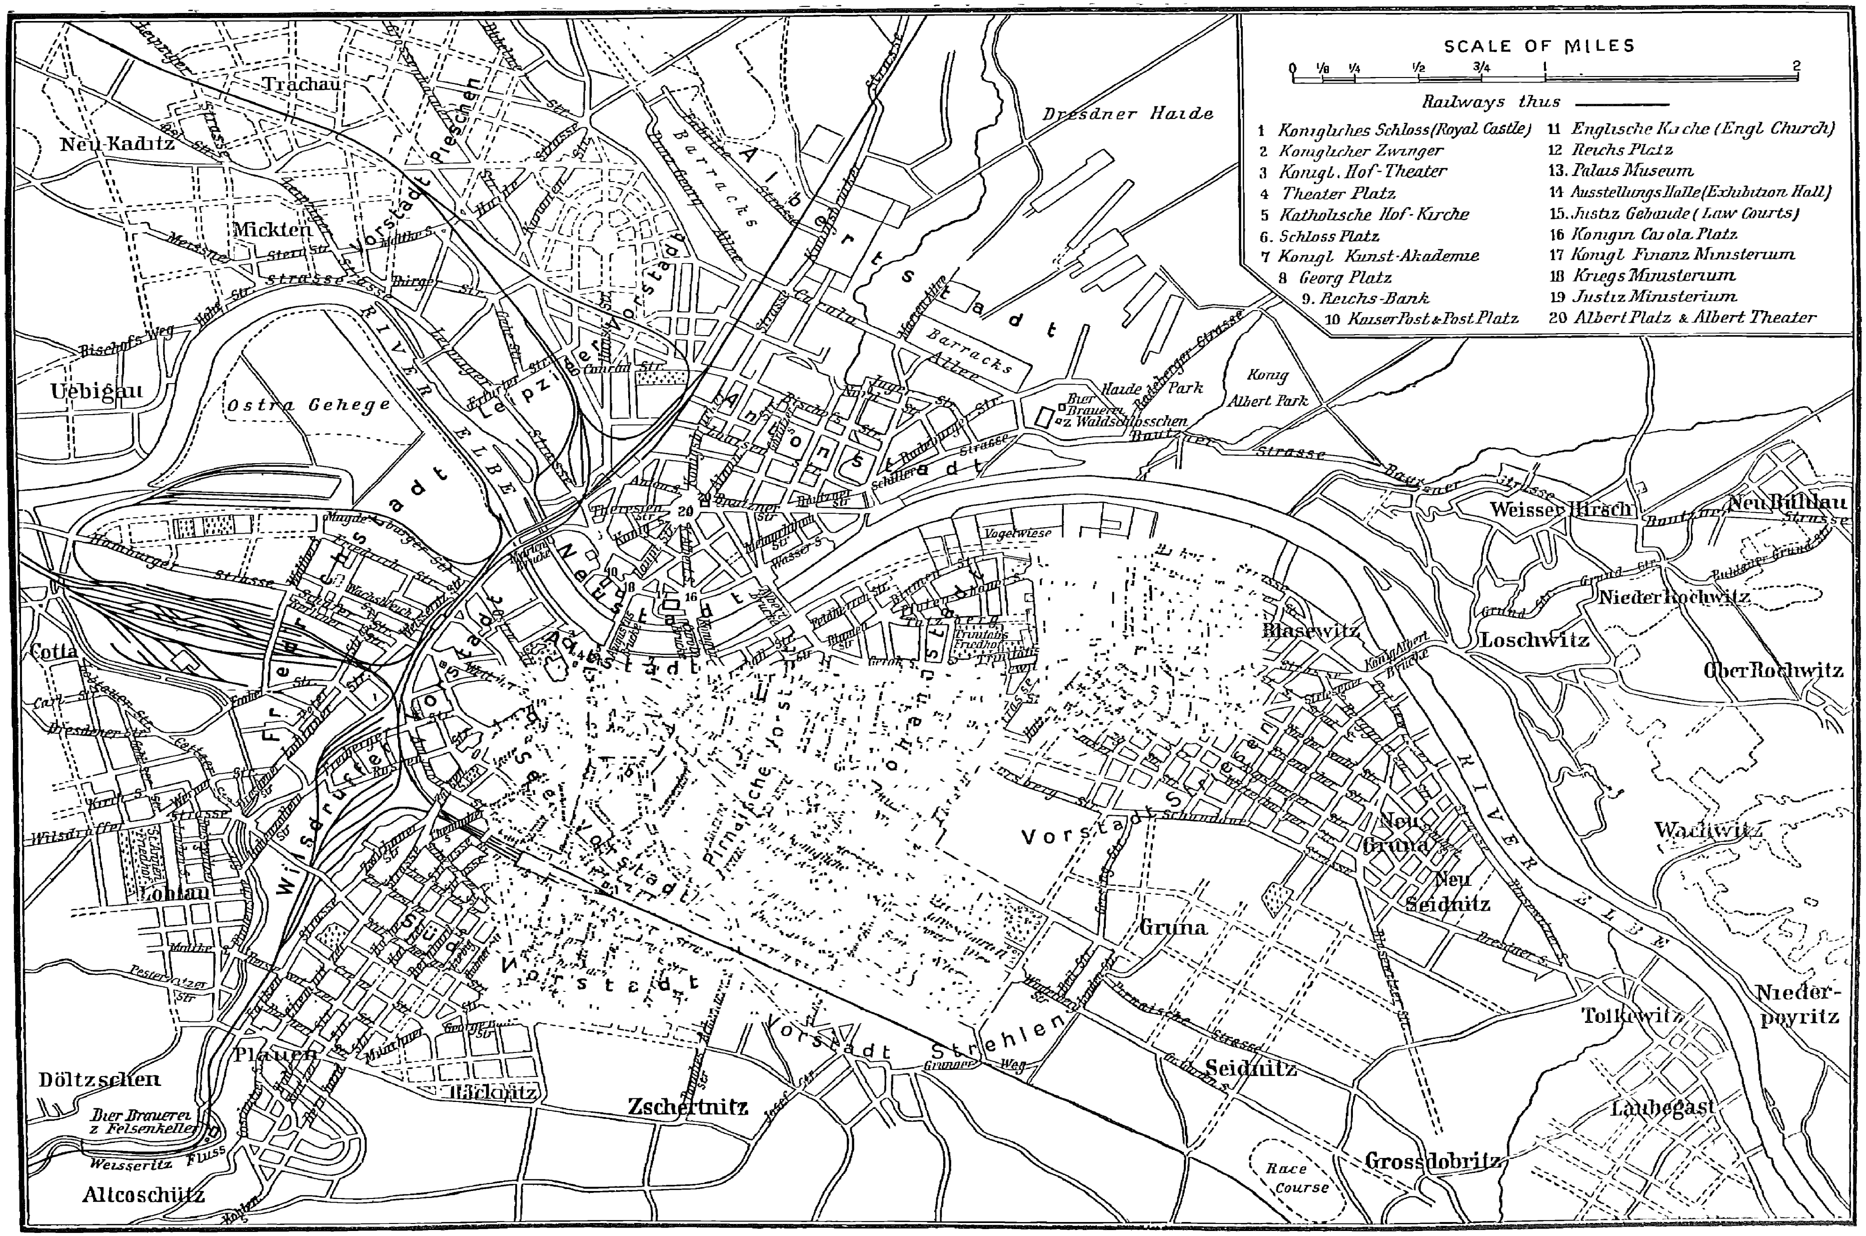
| | |
|---|---|
| Dredging | 1·425d. |
| Transportation | 1·68d. |
| Placing on bank | 1·3d. |
| Management, &c. | 0·22d. |
| Total | 4·625d. |

*River Loire.*—In 1897 the dredging of 1,233,670 cubic yds. with three bucket-ladder dredgers cost 2·5d. and 3·75d. per cubic yd., made up as follows:—

| | |
|---|---|
| Dredging | 1·25d. per cubic yd. |
| Transporting for a short distance and discharging from hoppers | 1·25d. ,, ,, |
| | 2·5d. ,, ,, |
| If discharged upon bank with floating elevator, including tow-boats, elevators, and barges | 3·75d. ,, ,, |
| Transport and discharge, transporting 21¾ miles | 4·65d. ,, ,, |

With suction dredger and transportation not exceeding 21¾ miles, the cost was 2·25d. per cubic yard. (W. H*.)

**Dresden** (the name is derived from the old Slav word *Drezga* = forest; *Drezgajan* = forest-dwellers), the capital city of the kingdom of Saxony, headquarters of the 12th German Army Corps, and the fifth largest town in the German Empire. It lies in a broad valley on both banks of the Elbe, 111 miles south from Berlin. Its delightful situation, no less than the richness of its art treasures and the educational advantages it offers, has ever made it a favourite resort of strangers, and during the last few years the numbers of foreigners who have made it their home have largely increased. Particularly is this the case with the so-called Russian, British, and American "colonies." Within two decades (1880–1900) Dresden almost at a bound advanced into the front ranks of German commercial and industrial towns; but whilst gaining in prosperity, it has lost much of its picturesque mediæval aspect. Old buildings in the heart of the Altstadt have been swept away, and their place occupied by modern business houses and new streets. König Johann-strasse has opened up the Altmarkt to the eastern suburbs, while the Schloss-strasse has been widened, an operation involving the demolition of the famous Georgenthor. The city, in its expansion in all directions, is gradually assimilating the more distant suburbs, which through a well-arranged tramway system are now brought into easy connexion with its centre. The prospect of the Elbe and of the undulating and pine-clad hills beyond, as formerly enjoyed from the Brühlsche Terrasse, has become somewhat marred, owing to the extension of the town up the river and to the two new bridges (both east of the old Augustus-brücke)—the Queen Carola-brücke, 1070 ft. long, resting on a couple of pillars in the stream, built in 1892–95, and the König Albert-brücke, 1037 ft. long, with four arches, each 102 ft. span, built in 1875–77. But in spite of its having become to a certain extent modernized, it cannot be denied that, architecturally, Dresden has gained in general embellishment by the new buildings which have lately been erected. In the old town the most striking of the new edifices is the Maler-akademie. It consists of a complex of buildings, constructed from designs by Lipsius, in the Italian Renaissance style, in the years 1890–94, and is profusely decorated with busts and medallions of famous artists, poets, and illustrious men. It contains not only the academy proper, but also the permanent exhibition of the Kunst-verein. The Albertinum, formerly the arsenal, built in 1559–63, was rebuilt in 1884–89, and fitted up as a museum of Oriental and classical antiquities, and as the depository of the state archives. There are also a bronze statue of Semper by Schilling (1891), a statue of Ludwig Richter by Kircheisen (1898), and the Moritz monument (removed here in 1895). The royal palace has undergone a radical restoration since 1890. The Brühl Palace is about to be reconstructed; the central portion of it is destined to form part of a new Parliament House for the kingdom. An elaborate equestrian monument of König Johann, by Schilling, unveiled in 1889, faces the Hoftheater. The latter is a magnificent creation, rebuilt after the designs of Semper on the site of the theatre burnt down in 1869, and was completed by his son Manfred in 1878. The exterior and interior are sumptuously decorated. In the old town there are further the Saxon industrial art museum, with a school, collection of drawings, and library attached; the Kreuz-kirche, rebuilt after destruction by fire in 1897; the municipal museum (antiquities, archives, coins, pictures, &c.); the Reformierte Kirche (1894); the Holy Trinity church; the Renaissance Victoria-Haus (1891–92); the Luther monument (1885), a copy of the Rietschel model at Worms; and the Dresdner Bank. In the suburbs which encircle the old town on west, south, and east there are to be noted the central railway station (1893–98), occupying the site of the old Böhmischer Bahnhof; a new station in the Neustadt, comprising the Leipziger and Schlesischer Bahnhöfe, is in course of construction; the vast premises of the municipal infirmary; the graves of Friedrich von Schlegel and von Weber (the musician) in the Roman Catholic cemetery; the bronze statue of Körner (1871), and a bust of Gutzkow (1887); in the Grosser Garten is the botanical garden, laid out in 1891, and a large exhibition building: the imposing law courts; the Johannes Kirche, richly sculptured in the interior; the Schilling Museum; and two ornamental fountains (Gerechtigkeit und Gänsedieb). On the right bank of the Elbe stands the fine ministry of finance (1896), the war ministry, the ministry of justice, the Körner Museum, and the Japanese Palace, this last containing the royal library of 400,000 vols., 6000 MSS., and 20,000 maps. Albert-platz is adorned with two fine fountains by Diez. In this same quarter are also the Luther church (1887) and the architects' school. On the Bismarck-platz is the technical high school, which since 1870 has enjoyed the privilege of conferring the degrees of doctor of engineering, doctor of technical sciences, &c. Beyond the Neustadt, and extending for more than a mile at half height on the range of hills which form its background, lies the Albertstadt, the military quarter, consisting of an imposing line of barracks and other military buildings, reference to which has been made in the article BARRACKS. Behind these stretches away the romantic pine forest—the so-called Dresdener Heide. Dresden is



Map of Dresden.

the seat of very various industries, its famous breweries occupying a prominent place. Population (1885), 246,086; (1890), 276,522; (1895), 336,440; (1900), 395,349.

**Dreux,** chief town of arrondissement, department of Eure-et-Loir, France, 20 miles north-north-west of Chartres, on railway from Paris to Granville. The manufacture of hardware and heavy iron goods has become important, as now are nurseries. There is considerable commerce in grain, fowls, and boots and shoes. The remains of Louis Philippe and his queen were brought from Weybridge, England, their first resting-place, in 1876, and interred in the chapel of St Louis. Population (1881), 6867; (1901), 9697.

**Drewenz,** a river of Germany. It rises south-east of Osterode in East Prussia, passes through the lake of Drewenz (7 miles long), and after a south-west course of 148 miles enters the Vistula from the right a little above Thorn. It is navigable only for rafts. Lake Drewenz is connected with Elbing (and so with the Baltic) by the navigable Elbing-Oberland Canal.

**Driffield, Great,** a market-town and railway station in the Buckrose parliamentary division of Yorkshire, England, 13 miles north of Beverley. All Saints' Church has been restored, and a Roman Catholic church, a Wesleyan Methodist chapel, and a new court-house have been erected. There are oil-cake works. Area of township (an urban district), 4998 acres. Population (1881), 5939; (1901), 5765. Area of ecclesiastical parish, 7599 acres. Population (1881), 6323; (1901), 6036.

**Drogheda,** a seaport in the county of Louth, Ireland, on the river Boyne and the Great Northern Railway, 31½ miles north of Dublin. It ceased to be a parliamentary borough in 1885, and a separate county in 1898, but it retains its mayor and corporation, which, however, has now practically the status of an urban district council. Steamers maintain almost daily communication with Liverpool, carrying chiefly agricultural produce of various kinds. In 1899, 454 vessels of 99,441 tons entered and 346 of 105,658 tons cleared. There are valuable salmon fisheries on the Boyne, which in 1899 gave employment to 711 persons. Population (1881), 12,297; (1901), 12,765. The area of the borough was extended in 1896, increasing the population by about 1500.

**Drohobycz,** a town in Galicia, Austria. Population (1890), 17,916 (6200 German, 4500 Ruthenians, the remainder Poles; the Jews number 8700); in 1900, 19,146. The principal industries are the production of salt (from the local brine wells), naphtha, and oil. Also considerable trade in cattle, corn, earthenware, and petroleum.

**Droitwich,** a municipal borough and market-town in the Droitwich parliamentary division (since 1885) of Worcestershire, England, 20½ miles south-west by south of Birmingham by rail. There are three parish churches. Recent erections are a Wesleyan chapel (rebuilt), new hospital, private bath hospital, St Andrew's Baths, and a large Salters' Hall. There are a town-hall and Royal Brine Baths. Owing to the pumping of the brine for the salt works there is a continual subsidence of the ground detrimental to the buildings, and the houses are now mostly built in the suburbs. Area, 1856 acres. Population (1881), 3761; (1901), 4163.

**Drôme,** a department in the south-east of France, traversed by the Alps of Vercors and watered by the Rhône, the Isère, and the Drôme.

Area, 2533 square miles. The population, numbering 314,615 in 1886, decreased to 294,704 in 1901. Births in 1899, 5802, of which 259 were illegitimate; deaths, 6405; marriages, 2126. There were, in 1896, 908 schools with 44,000 pupils; the illiterate form 3 to 4 per cent. of the population. The area under cultivation in 1896 amounted to 1,242,985 acres; 644,968 acres arable, and 358,314 acres forest. The wheat crop in 1899 yielded a value of £1,110,000; mangel-wurzel, £103,000; potatoes, £420,000; grass lands, £190,000; olive, £21,000; mulberry, £61,000. The production of silkworm cocoons is one of the largest among those of the departments of France, amounting in 1899 to 25,320 cwts. avoir. The live-stock in 1899 included 17,290 horses, 13,850 asses, 421,000 sheep, 120,540 pigs, and 96,750 goats. Mining and metallurgy are in a backward state. The textile industry is more advanced. Valence, the capital, has 25,000 inhabitants.

**Droylsden,** a township and parish in the Prestwich parliamentary division of Lancashire, England, formed in 1844, in the civil parish of Manchester, 4 miles east of Manchester by rail. There are an educational institute, and a Moravian theological college. The industries comprise cotton spinning, chemical and dye works, brickmaking, and iron-founding. Area of urban district, 1014 acres. Population (1881), 8687; (1901), 11,087.

**Droysen, Johann Gustav** (1808–1884), German historian, was born 6th July 1808 at Treptow, Pomerania. His father was a pastor who held several cures in Pomerania, and was chaplain to a regiment of cuirassiers, in which capacity he was present at the celebrated siege of Kolberg in 1806–7. The young Droysen, as a child, was also witness of some of the military operations during the War of Liberation, for his father was pastor of Greifenhagen, in the immediate neighbourhood of Stettin, which was held by the French during the greater part of 1813. The impressions of these early years laid the foundation of the ardent attachment to Prussia which distinguished him, as so many other historians of his generation. He was educated at the gymnasium of Stettin and at the University of Berlin; in 1829 he became a master at the Graue Kloster (or Grey Friars), one of the oldest schools in Berlin; besides his work there he gave lectures at the university, from 1833 as privat-docent, and from 1835 as Professor, without a salary. During these years he was occupied with classical antiquity; he published a translation of Æschylus and a paraphrase of Aristophanes, but the work by which he made himself known as an historian was his *Life of Alexander the Great*, published in 1832, a book which still remains probably the best work on the subject. It was in some ways the herald of a new school of German historical thought, for it shows that idealization of power and success which he had learnt from the teaching of Hegel. It was followed by other volumes dealing with the successors of Alexander, published under the title of *The History of Hellenism*. A new and revised edition of the whole work was published in 1885; it has been translated into French, but not into English. In 1840 Droysen was appointed Professor of History at Kiel. He was at once attracted into the political movement for the defence of the rights of the Elbe Duchies, of which Kiel was the centre. Like his predecessor Dahlmann, he placed his historical learning at the service of the Estates, and composed the address of 1844, in which the Estates protested against the claim of the king of Denmark to alter the law of succession in the Duchies. In 1848 he was elected as a member of the Frankfort Parliament, and acted as secretary to the committee for drawing up the Constitution. He was a determined supporter of Prussian ascendancy, and was one of the first members to retire after the king of Prussia refused the crown in 1849. During the next two years he continued to support the cause of the Duchies, and in 1850, with Carl Samwer, he published a history of the dealings of Denmark with Schleswig-Holstein, *Die Herzogthümer Schleswig-Holstein und das Königreich Dänemark seit dem Jahre 1806*, Hamburg, 1850. A translation was published in London in the same

year under the title *The Policy of Denmark towards the Duchies of Schleswig-Holstein.* The work was one of great political importance, and had much to do with the formation of public opinion on the rights of the Duchies in their struggle with Denmark. After 1851 it was impossible for him to remain at Kiel, and he was appointed to a professorship at Jena; in 1859 he was called to Berlin, where he remained till his death in 1884. In his later years he was almost entirely occupied with Prussian history. In 1851 he brought out a life of Count Yorck v. Wartenberg, one of the best biographies in the German language, and then began his great work on the *History of Prussian Policy*, Berlin, 1855–86. Seven volumes were published, the last not till after his death. It forms a complete history of the growth of the Prussian monarchy down to the year 1756. This, like all Droysen's work, shows a strongly marked individuality, and a great power of tracing the manner in which important dynamic forces worked themselves out in history. This quality also gave him great influence as a teacher. Droysen was twice married; his eldest son, Gustav, is the author of several well-known historical works, namely, *Life of Gustavus Adolphus* (Leipzig, 1869–70); *Life of Bernhard of Saxe-Weimar*, London, 1885; a *History of the Thirty Years' War* in Oncken's Universal History; and an admirable *Historical Atlas.* Another son, Hans Droysen, is the author of some works on Greek history and antiquities. (J. W. HE)

**Drummond, Henry** (1851–1897), Scottish evangelical writer and lecturer, was born in Stirling on 17th August 1851. He was educated at Edinburgh University, where he displayed a strong inclination for physical and mathematical science. The religious element was an even more powerful factor in his nature, and disposed him to enter the Free Church of Scotland. While preparing for the ministry, he was for a time carried away by the evangelizing mission of Messrs Moody and Sankey, in which he actively cooperated for two years. In 1875 he became Lecturer on Natural Science in the Free Church College, which enabled him to combine all the pursuits for which he felt a vocation. His studies resulted in a book whose title expressed the mediating position he was called upon to occupy, *Natural Law in the Spiritual World.* As it was about to issue from the press (1883), a sudden invitation from the African Lakes Company drew him away to Central Africa. Upon his return in the following year he found himself famous. Large bodies of serious readers, alike among the religious and the scientific classes, discovered in *Natural Law* the common standing-ground which they needed; and the universality of the demand proved, if nothing more, the seasonableness of its publication. Drummond continued to be actively interested in missionary and other movements among the Free Church students. In 1888 he published *Tropical Africa*, a valuable digest of information. In 1890 he travelled in Australia, and in 1893 delivered the Lowell Lectures at Boston. It had been his intention to reserve them for mature revision, but an attempted piracy compelled him to hasten their publication, and they appeared in 1894 under the title of *The Ascent of Man.* Their object was to vindicate for altruism, or the disinterested care and compassion of animals for each other, an important part in effecting "the survival of the fittest," a thesis previously maintained by Professor Fiske. Drummond's health failed shortly afterwards, and he died on 11th March 1897. His character was full of charm. His writings are too nicely adapted to the needs of his own day to justify the expectation that they will long survive it, but few men have exercised more influence upon certain circles in their own generation. (R. G.)

**Dublin,** a maritime county of Ireland, province of Leinster, bounded on the N. by Meath, on the E. by the Irish Sea, on the W. by Kildare and Meath, and on the S. by Wicklow. The area of the administrative county in 1900 was 226,686 acres, of which 68,913 were tillage, 122,373 pasture, 502 fallow, 3986 plantation, 1194 marsh, 55 turf bog, 13,305 barren mountain, and 16,358 water, roads, fences, &c. The new administrative county under the Local Government (Ireland) Act, 1898, does not include the portion of the township of Bray formerly situated in Dublin. The population in 1881 was 418,910, and in 1891, 419,216, of whom 197,409 were males and 221,807 females, divided as follows among the different religions: Roman Catholics, 322,822; Protestant Episcopalians, 77,896; Presbyterians, 7724; Methodists, 4129; and other denominations, 6645. The increase of population between 1881 and 1891 was ·07. The average number of persons to an acre (including the city of Dublin) was 1·85, being by far the largest number of any county in Ireland. Of the total population, 66,675 persons inhabited the rural districts, being an average of 241 persons to each square mile under crops and pasture. The population in 1901 was 447,266 (Roman Catholics, 348,701; Protestant Episcopalians, 78,921; Presbyterians, 7538; Methodists, 4464; others, 7642), being an increase of 7·3 per cent. The following table gives the number of births, deaths, and marriages in various years:—

| Year. | Births. | Deaths. | Marriages. |
|---|---|---|---|
| 1881 | 12,047 | 10,839 | 2987 |
| 1891 | 11,496 | 10,322 | 2943 |
| 1899 | 12,055 | 11,806 | 3178 |

In 1899 the birth-rate per 1000 was 28·9, and the death-rate 28·3; the rate of illegitimacy was 2·7 per cent. of the total births. The total number of emigrants who left the county between 1st May 1851 and 31st December 1899 was 110,832, of whom 61,751 were males and 49,081 females. The county contains the following townships, which are all practically suburbs of Dublin: Rathmines and Rathgar (27,706), Pembroke (24,269), Blackrock (8401), Kilmainham (6510), Drumcondra, Clonliffe, and Glasnevin (7621), and Clontarf (5104), and the town of Kingstown (17,352), the populations given in each case being those of 1891. In 1901 the population of the urban districts of Rathmines and Rathgar, Pembroke, Blackrock, and Kingstown was respectively 32,472, 25,524, 8719, and 17,356.

*Education.*—The following table gives the degree of education (excluding the city of Dublin) in 1891:—

| | Males. | Females. | Total. | Percentage. | | |
|---|---|---|---|---|---|---|
| | | | | R. C. | Pr.Ep. | Presb. |
| Read and write | 58,710 | 72,458 | 131,168 | 78·1 | 94·7 | 95·1 |
| Read only | 4,653 | 5,853 | 10,506 | 8·7 | 2·1 | 1·9 |
| Illiterate | 8,130 | 7,836 | 15,966 | 13·2 | 3·2 | 3·0 |

The percentage of illiterates among Roman Catholics in 1881 was 17·1. Excluding the city of Dublin, the number of superior schools in 1891 was 80, with 5338 pupils (Roman Catholics 2392 and Protestants 2946), and 284 primary schools with 23,891 pupils (Roman Catholics 19,478 and Protestants 4513). The number of pupils on the rolls of the national schools on 30th September 1899 was 55,405, of whom 46,256 were Roman Catholics and 9149 Protestants.

*Administration.*—The county is divided into two parliamentary divisions, north and south, the number of registered electors in 1900 being respectively 12,429 and 10,762. The ratable value in 1900 (excluding the county borough of Dublin) was £859,044. By the Local Government (Ireland) Act, 1898, the fiscal and administrative duties of the grand jury and (to a less extent) of other bodies were transferred to a county council, urban and rural district councils were established, and under that Act the county now comprises 9 urban and 5 rural sanitary districts. The city of Dublin constitutes a separate county.

*Agriculture.*—The following tables show the acreage under crops, including meadow and clover, and the amount of live-stock in 1881, 1891, 1895, and 1900. The figures for 1900 are for the new administrative county:—

| Year. | Wheat. | Oats. | Barley, Beans, &c. | Potatoes. | Turnips. | Other Green Crops. | Meadow and Clover. | Total. |
|---|---|---|---|---|---|---|---|---|
| 1881 | 5599 | 14,212 | 2282 | 9831 | 2045 | 3846 | 50,909 | 88,724 |
| 1891 | 4023 | 11,915 | 2436 | 8053 | 2315 | 3701 | 41,048 | 73,491 |
| 1895 | 2392 | 12,325 | 2587 | 7459 | 2407 | 3159 | 44,553 | 74,882 |
| 1900 | 3056 | 9,887 | 1995 | 6666 | 2363 | 3705 | 41,241 | 89,113 |

For 1899 the total value of the cereal and other crops was estimated by the Registrar-General at £470,899. The number of acres under pasture in 1881 was 103,698; in 1891, 118,355; and in 1900, 122,373.

| Year. | Horses and Mules. | Asses. | Cattle. | Sheep. | Pigs. | Goats. | Poultry. |
|---|---|---|---|---|---|---|---|
| 1881 | 22,060 | 1881 | 57,683 | 50,440 | 13,460 | 5327 | 236,018 |
| 1891 | 22,502 | 1862 | 68,516 | 78,443 | 12,794 | 5766 | 250,093 |
| 1895 | 24,550 | 1941 | 61,534 | 57,365 | 11,095 | 4718 | 265,801 |
| 1900 | 22,492 | 2055 | 70,355 | 69,578 | 8,983 | 3619 | 249,147 |

The number of milch cows in 1891 was 17,322, and 1900, 17,748. It is estimated that the total value of cattle, sheep, and pigs in 1899 was £1,140,644. In 1900 the number of holdings not exceeding 1 acre was 2997, between 1 and 5, 1651, between 5 and 15, 1628, between 15 and 30, 911, between 30 and 50, 585, between 50 and 100, 628, between 100 and 200, 387, between 200 and 500, 138, and above 500, 13—total 8938. The number of loans issued (the number of loans being the same as the number of tenants) under the Land Purchase Acts, 1885, 1891, and 1896, up to 31st March 1900, was 148, amounting to £170,350. The number of loans sanctioned for agricultural improvements under sect. 31 of the Land Act, 1881, between 1882 and 1900 was 202, and the amount issued was £25,030. The total amount issued on loan for all classes of works under the Land Improvement Acts from the commencement of operations in 1847 to 31st March 1900, was £98,770.

*Fisheries.*—In 1899, 134 vessels, employing 546 hands, were registered in the deep sea and coast fishing district of Kingstown. In the same year 175 persons were employed in the salmon fishery district of Dublin. (W. H. Po.)

**Dublin,** a maritime city, county and parliamentary borough, metropolis of Ireland, on the river Liffey, 292 miles west-north-west of London. The population in 1881 was 249,602; in 1891, 245,001, of whom 117,503 were males and 127,498 females, divided as follows among the different religions: Roman Catholics, 201,418; Protestant Episcopalians, 35,125; Presbyterians, 3492; Methodists, 1708; and other denominations, 3258. The population in 1901 was 289,108, the increase being due to the extension of the municipal area in 1900. Between 1891 and 1901 the population of the chief suburbs also increased, as will be seen from the following figures:—Rathmines and Rathgar (1891), 27,796; (1901), 32,472; Pembroke (1891), 23,992; (1901), 25,524; Blackrock (1891), 8401; (1901), 8719; Kingstown (1891), 17,183; (1901), 17,356. Of recent years blocks of artisans' dwellings have been erected, some from a fund provided by the munificence of Lord Iveagh in 1889. The following table shows the standard of general education attained in 1891:—

| | Males. | Females. | Total. | Percentage. | | | |
|---|---|---|---|---|---|---|---|
| | | | | Roman Cath. | Protes. Epis. | Presby-terians. | Metho-dists. |
| Read and write | 83,294 | 85,897 | 169,191 | 74·6 | 92·2 | 94·5 | 95·3 |
| Read only . . | 6,890 | 10,020 | 16,910 | 8·8 | 3·1 | 2·6 | 2·0 |
| Illiterate . . | 13,520 | 17,996 | 31,516 | 16·6 | 4·7 | 2·9 | 2·7 |

In 1881 the percentage of illiterates among Roman Catholics was 18·1, among Protestant Episcopalians 5·2, among Presbyterians 3·5, and among Methodists 3·5. In 1891 there were 40 superior schools with 4024 pupils (Roman Catholics 2238, and Protestants 1786), and 197 primary schools with 26,513 pupils (Roman Catholics 21,117, and Protestants 5296). The yearly average of births registered in the registration district (population in 1891, 349,594) between 1890 and 1899, both inclusive, was, males 5200, and females 4952, and of deaths registered, males 4711, and females 4859. The number of persons proceeded against in the metropolitan police district in 1899 for indictable offences was 1256, of whom 933 were convicted or committed for trial; for non-indictable offences, 36,195, of whom 27,752 were fined and 2785 otherwise punished. Though the number of public-houses within the same limits fell from 897 in 1896 to 888 in 1899, the charges of drunkenness (including cases where some other offence was charged) rose from 7677 in 1896 to 9277 in 1899.

Something has been done since 1880 to improve the condition of the poorer parts of the city, but only a few important changes have been effected in the outward aspect of the city. The restoration of Christchurch Cathedral was completed in 1878. What was then known as Carlisle Bridge was rebuilt in 1880, and now under its name of O'Connell Bridge forms one of the finest structures of its kind in the United Kingdom. The Royal University, established in 1880, is housed in the permanent building of the International Exhibition of 1865, to which many additions have been made. It possesses a fine hall, much used for concerts. In the same year St Stephen's Green, converted into a public park at the expense of Lord Ardilaun, was opened to the public; a statue of its donor has been erected in it. Statues have also been erected of Father Mathew, the temperance reformer, in Sackville Street, and of Surgeon-Major Parke and Sir R. P. Stewart in Leinster Lawn, Merrion Square. The most noteworthy new building is the museum and library of the Royal Dublin Society, erected at a cost of about £150,000, and opened in 1890. To it were transferred the collection of Irish antiquities belonging to the Royal Irish Academy and the old library from Leinster House. Considerable attention has been paid of late years to providing facilities for the travelling public. A loop line now connects the various railway systems, thus facilitating the transit of passengers and goods between the various parts of Ireland and between England and Ireland. Steam tramways are in operation between Parkgate Street and Lucan and between Terenure and Blessington, and electric trams connect all the important suburban districts with the city.

*Administration.*—Dublin was formerly represented by two members of Parliament, but in 1885 the parliamentary borough, the population of which in 1901 was 286,328, was divided into four divisions, College Green, Harbour, St Stephen's Green, and St Patrick's, each returning one member. The number of registered electors in 1900 was 38,361. Dublin University, with a constituency of over 4000, returns two members. In 1898 Dublin was constituted a county borough, but the position and duties of its corporation were otherwise left practically unaltered. The ratable value in 1900 was £742,413, and the total receipts of the corporation in 1898 were £565,448. A new body was created in 1898 for governing the port and harbour, comprising the Lord Mayor, six members of the corporation, twelve traders' members, and nine shipping members. A scheme is on foot for reviving the shipbuilding industry in Dublin.

*Commerce and Shipping.*—By continual dredging a greater depth of water is now available in the harbour than ever before. The Custom House Docks, which cover an area of about 8 acres, have 16 feet of water and can accommodate 40,000 tons of shipping. A basin constructed by the Port and Docks Board was named the Alexandra Basin by the Prince and Princess of Wales in April 1885. The lighting of the harbour has also been much improved, and a fog siren placed at Poolbeg light-

house. Dublin continues to produce little for exportation except whisky and porter. Since 1895 whisky has been exported in the following quantities:—

| Years. | Butts and Puncheons. | Hogsheads. | Casks. | Quarter Casks. |
|---|---|---|---|---|
| 1895 | 4521 | 15,519 | 2765 | 8989 |
| 1896 | 5192 | 14,696 | 2635 | 9231 |
| 1897 | 4947 | 13,398 | 3509 | 8181 |
| 1898 | 4762 | 15,401 | 2621 | 9156 |
| 1899 | 5092 | 13,955 | 2159 | 8985 |

The number of hogsheads of porter exported in 1895 was 379,131; in 1896, 376,199; in 1897, 377,247; in 1898, 368,628; and in 1899, 409,415. The number of horses exported to Great Britain in 1899 was 13,814; of cattle, 304,187; of sheep and lambs, 406,709; and of pigs, 327,980. The value of British and Irish produce exported direct to foreign countries has considerably declined of late years. In 1893 it was £155,243; in 1896, £68,809; and in 1899, £63,385. The total value of the foreign and colonial imports in 1899, which included 89,157 tons of wheat, 100,475 tons of maize, 739,549 sacks and bags of flour, and 51,653 quarters of barley, was £2,565,817. The total amount of customs duties collected at the port in the same year was £615,566, as compared with £804,214 in 1894 and £817,391 in 1890. In 1899 the harbour receipts derived from tonnage and quay wall dues on shipping amounted to £58,727. The following table shows the number of vessels in the foreign and coasting trades that entered and cleared with cargoes from the port, and the number of vessels registered from 1895 to 1899:—

| Years. | Entered. | | Cleared. | | Registered. | |
|---|---|---|---|---|---|---|
| | Vessels. | Tonnage | Vessels. | Tonnage. | Vessels. | Tonnage. |
| 1895 | 7171 | 1,745,409 | 4484 | 1,170,948 | 329 | 58,657 |
| 1896 | 7047 | 1,769,065 | 4526 | 1,215,806 | 327 | 59,877 |
| 1897 | 7085 | 1,800,564 | 4499 | 1,213,444 | 322 | 63,456 |
| 1898 | 7174 | 1,764,223 | 4612 | 1,226,111 | 318 | 60,916 |
| 1899 | 7247 | 1,804,175 | 4549 | 1,220,700 | 317 | 61,667 |

(W. H. PO.)

**Dubois**, a borough of Clearfield county, Pennsylvania, U.S.A., at the intersection of three railways, the Allegheny Valley, the Buffalo, Rochester, and Pittsburg, and the Pennsylvania. It is in the midst of a coal-mining region, and its industries consist largely in handling coal. Population (1880), 2718; (1890), 6149; (1900), 9375, of whom 1655 were foreign-born.

**Dubois, Clément Francois Théodore** (1837-——), French musical composer and director of the Paris Conservatoire, was born at Rosnay on 24th August 1837. He studied at the Conservatoire under Ambroise Thomas, and won the Grand Prix de Rome in 1861 with a cantata entitled *Atala*. After the customary sojourn in Rome, Dubois returned to Paris and devoted himself to teaching. He was appointed "maître de Chapelle" at the Church of Ste Clotilde, where César Franck was organist, in 1863, and remained at this post for five years, during which time he composed a quantity of sacred music, notably *Les Sept Paroles du Christ* (1867), a work which has become well known in France. In 1868 he became "maître de Chapelle" at the Church of the Madeleine, and nine years later succeeded Camille Saint-Saëns there as organist. He became Professor of Harmony at the Conservatoire in 1871, and was appointed Professor of Composition in succession to Léo Delibes in 1891. At the death of Ambroise Thomas in 1896, he became director of the Conservatoire. Dubois is an extremely prolific composer, and has written in a variety of forms. His sacred works include four masses, a requiem, *Les Sept Paroles du Christ*, a large number of motets and pieces for organ. For the theatre he has composed *La Guzla de l'Emir*, an opéra comique in one act, played at the Théâtre Lyrique de l'Athénée in 1873; *Le Pain Bis*, an opéra comique in one act, given at the Opéra Comique in 1879; *La Farandole*, a ballet in three acts, produced at the Grand Opéra in 1883; *Aben-Hamet*, a four-act opera, heard at the Théâtre Italien in 1884; *Xavière*, a dramatic idyll in three acts, played at the Opéra Comique in 1895. His orchestral works include two concert overtures, the overture to *Frithioff* (1880), several suites, *Marche Héroïque de Jeanne d'Arc* (1888), &c. He is also the author of *Le Paradis Perdu*, an oratorio which gained for him the prize offered by the City of Paris in 1878; *L'Enlèvement de Proserpine* (1879), a *scène lyrique*; *Délivrance* (1887), a cantata; *Hylas* (1890), a *scène lyrique* for soli, chorus, and orchestra. In addition, he has composed much for the piano and voice. If his musical personality is not a very marked one, M. Dubois is nevertheless a musician of lofty aims and undoubted ability.

**Dubois, Paul** (1829-——), French sculptor and painter, was born at Nogent-sur-Seine, 18th July 1829. He studied law to please his family and art to please himself, and finally abandoned the former in favour of the latter, and placed himself under Toussaint. For a short while a student at the École des Beaux Arts, M. Dubois sojourned in Rome, and by the study there of the great masters of sculpture developed his eye and his feeling for form so that he well-nigh equalled the greatest in knowledge and refinement. His first contributions to the Salon (1860) were busts of "The Countess de B." and "A Child." For his first statues, "St John the Baptist" and "Narcissus at the Bath" (1863), Dubois was awarded a medal of the second class. The statue of "The Infant St John," which had been modelled in Florence in 1860, was exhibited in Paris in bronze, and was acquired by the Luxembourg Museum. "A Florentine Singer of the Fifteenth Century," to this day one of the most popular statuettes "published" in Europe, was shown in 1865, and at once attracted great attention. "The Virgin and Child" appeared in the Paris Universal Exhibition in 1867; "The Birth of Eve" was produced in 1873, and was followed by striking busts of Henner, Dr Parrot, Paul Baudry, Dr Pasteur, Gounod, and Bonnat, remarkable alike for life, vivacity, likeness, refinement, and subtle handling. His chief work was "The Tomb of General Lamoricière," a brilliant masterpiece, conceived in the Renaissance spirit, with allegorical figures and groups representing Warlike Courage, Charity, Faith, and Meditation, as well as bas-reliefs and enrichments; the two first-named works were separately exhibited in the Salon of 1877. The medallions represent Wisdom, Hope, Justice, Force, Rhetoric, Prudence, and Religion. The statue of the "Constable Anne de Montmorency" was executed for Chantilly, and that of "Joan of Arc" (1889) for the town of Rheims. The Italian influence which characterizes Dubois's earlier work disappears as his own individuality became clearly asserted. As a painter M. Dubois has restricted himself mainly to portraiture, "My Children" (1876) being probably the most noteworthy. His work in painting is of a high order, admirable alike in colour, drawing, and taste. His drawings and copies after the Old Masters are also of peculiar excellence: they include "The Dead Christ" (after Sebastian del Piombo) and "Adam and Eve" (after Raphael). In 1873 M. Dubois was appointed Keeper of the Luxembourg Museum, which contains the "Infant St John" and several other works from his hand. He succeeded M. Guillaume as Director of the École des Beaux Arts, 1878; and Perraud as member of the Académie des Beaux Arts. Twice at the Salon he

obtained the Medal of Honour (1865 and 1876), and once at the Universal Exhibition (1878). He also won numerous other distinctions, and was appointed Grand Cross of the Legion of Honour. He is a member of several European orders, and in 1895 received the rare distinction of election as Honorary Foreign Academician of the Royal Academy of London.

**Du Bois-Reymond, Emil** (1818–1896), German physiologist, was born in Berlin on 7th November 1818. The Prussian capital was the place both of his birth and of his life's work, and he will always be counted among Germany's great scientific men, yet he was not of German blood. His father belonged to Neufchatel, his mother was of Huguenot descent, and he has spoken of himself as "being of pure Celtic blood." Educated first at the French College in Berlin, then at Neufchatel, whither his father had returned, he entered in 1836 the University of Berlin. He seems to have been uncertain at first as to the bent of his studies, for he sat at the feet of the great ecclesiastical historian Neander, and dallied with geology; but eventually he threw himself into the study of medicine, with such zeal and success as to attract the notice of the great teacher of anatomy and physiology, who was then making Berlin famous as a school for the sciences ancillary to medicine. Johannes Müller may be regarded as the central figure in the history of modern physiology, the physiology of the 19th century. Müller's earlier studies had been distinctly physiological; but his inclination, no less than his position as Professor of Anatomy as well as of Physiology in the University of Berlin, led him later on into wide studies of comparative anatomy, and these, aided by the natural bent of his mind towards problems of general philosophy, gave his views of physiology a breadth and a depth which profoundly influenced the progress of that science in his day. He had, about the time when the young Du Bois-Reymond came to his lectures, published his great *Elements of Physiology*, the dominant note of which may be said to be this:—"Though there appears to be something in the phenomena of living beings which cannot be explained by ordinary mechanical, physical, or chemical laws, much may be so explained, and we may without fear push these explanations as far as we can, so long as we keep to the solid ground of observation and experiment." Müller recognized in the Neufchatel lad a mind fitted to carry on physical researches into the phenomena of living things in a legitimate way. He made him in 1840 his assistant in physiology, and as a starting-point for an inquiry put into his hands the essay which the Italian Matteucci had just published on the electric phenomena of animals. This determined the work of Du Bois-Reymond's life. He chose as the subject of his graduation thesis "Electric Fishes," and so commenced a long series of investigations on animal electricity, by which he enriched science and made for himself a name. The results of these inquiries were made known partly in papers communicated to scientific journals, but also and chiefly in his work *Researches on Animal Electricity*, the first part of which appeared in 1848, the last in 1884.

This great work may be regarded under two aspects. On the one hand it is a record of the exact determination and approximative analysis of the electric phenomena presented by living beings. Viewed from this standpoint, it represents a remarkable advance of our knowledge. Du Bois-Reymond, beginning with the imperfect observations of Matteucci, built up, it may be said, this branch of science. He did so by inventing or improving methods, by devising new instruments of observation or by adapting old ones. The debt which science owes to him on this score is a large one indeed. On the other hand, the volumes in question contain an exposition of a theory. In them Du Bois-Reymond put forward a general conception by the help of which he strove to explain the phenomena which he had observed. He developed the view that a living tissue, such as muscle, might be regarded as composed of a number of electric molecules, of molecules having certain electric properties, and that the electric behaviour of the muscle as a whole under varying circumstances was the outcome of the behaviour of these native electric molecules. It may perhaps be said that this theory has not stood the test of time so well as have Du Bois-Reymond's other more simple deductions from observed facts. It was early attacked by Ludimar Hermann, who maintained that a living untouched tissue, such as a muscle, is not the subject of electric currents so long as it is at rest, is isoelectric in substance, and therefore need not be supposed to be made up of electric molecules, all the electric phenomena which it manifests being due to internal molecular changes associated with activity or injury. Although most subsequent observers have ranged themselves on Hermann's side, it must nevertheless be admitted that Du Bois-Reymond's theory was of great value if only as a working hypothesis, and that as such it has greatly helped in the advance of science.

Du Bois-Reymond's work lay chiefly in the direction of animal electricity, yet he carried his inquiries—such as could be studied by physical methods—into other parts of physiology, more especially into the phenomena of diffusion, though he published little or nothing concerning the results at which he arrived. For many years, too, he exerted a great influence as a teacher. In 1858, upon the death of Johannes Müller, the chair of Anatomy and Physiology, which that great man had held, was divided into a chair of Human and Comparative Anatomy, which was given to Reichert, and a chair of Physiology, which naturally fell to Du Bois-Reymond. This he held to his death, carrying out his researches for many years under the unfavourable circumstances of inadequate accommodation. In 1877, through his influence, the Government provided the University with a proper physiological laboratory. In 1851 he was admitted into the Academy of Sciences of Berlin, and in 1867 became its Perpetual Secretary. For many years he and his friend Helmholtz, who like him had been a pupil of Johannes Müller, were prominent men in the German capital. Acceptable at Court, they both used their position and their influence for the advancement of science. Both, from time to time as opportunity offered, stepped out of the narrow limits of the professorial chair and gave the world their thoughts concerning things on which they could not well dwell in the lecture-room. Du Bois-Reymond, as has been said, had in his earlier years wandered into fields other than those of physiology and medicine, and in his later years he went back to some of these. His occasional discourses, dealing with general topics and various problems of philosophy, show that to the end he possessed the historic spirit which had led him as a lad to listen to Neander; they are marked not only by a charm of style, but by a breadth of view such as might be expected from Johannes Müller's pupil and friend. He died in the city of his birth and adoption on 26th November 1896. (M. F.)

**Dubuque,** capital of Dubuque county, Iowa, U.S.A., and in 1900 the second city in size in the state, in 42° 30′ N. lat. and 90° 40′ W. long., on the western bank of the Mississippi, at an altitude on the river bank of 611 feet. The business part stands in the level bottom land at the foot of the bluffs, while the residence portion climbs the

bluffs, 200 feet or more, and spreads over the high prairie above. The city is divided into five wards, is well paved with brick, macadam, and gravel, and is connected with the other side of the Mississippi by two bridges. It is entered by four great railway systems, the Chicago, Burlington, and Quincy, the Chicago Great Western, the Chicago, Milwaukee, and St Paul, and the Illinois Central. These, with steamboat lines on the river, give the city a large commerce. Its manufactures had, in 1900, an invested capital of $8,117,358, an average number of 5503 wage-earners receiving $2,012,153 in wages, and a product valued at $10,952,204. The chief articles of manufacture were lumber, men's clothing, carriages and waggons, and malt liquors. The assessed valuation of real and personal property was, in 1900, $23,907,583, the net debt $1,617,020, and the rate of taxation $37 per $1000. The lead and zinc mines of the adjacent region, which first induced the settlement of Dubuque, are at present producing but little. Population (1880), 22,254; (1890), 30,311; (1900), 36,297, of whom 6955 were foreign-born and 115 negroes. The death-rate in 1900 was about 12.

**Ducamp, Maxime** (1822–1894), French writer, the son of a successful surgeon, was born in Paris, 8th February 1822. He had a strong taste for travel, which his father's means enabled him to indulge as soon as his college days were over. Between 1844 and 1845, and again between 1849 and 1851, he travelled in Europe and the East, and made excellent use of his experiences in books published after his return. In 1851 he was one of the founders of the *Revue de Paris*, to which he contributed for some six or seven years. In 1853 he was made an officer of the Legion of Honour. In 1870 he was nominated for the Senate, but his election was frustrated by the downfall of the Empire. He was elected a member of the French Academy in 1880, mainly, it is said, on account of his history of the Commune, published under the title of *Les Convulsions de Paris* (1878–80). His writings include *Paris* (6 vols., 1869–75), and the entertaining *Souvenirs Littéraires* (1882). The latter book contains much information respecting Flaubert, of whom Ducamp was an early and intimate friend. He died on 9th February 1894. Ducamp was one of the earliest amateur photographers, and his books of travel were among the first to be illustrated by means of what was then a new art. (R. F. S.)

**Du Chaillu, Paul Belloni** (1835-——), traveller and anthropologist, was born at New Orleans on 31st July 1835, and in his youth accompanied his father, an African trader, to the West Coast of Africa. From 1855 to 1859 he regularly explored the regions bordering upon the equator, and his travels resulted in the rediscovery of the great anthropoid ape called the gorilla, mentioned by Carthaginian navigators, and not entirely unknown to modern science, but practically forgotten. A subsequent expedition, from 1863 to 1865, enabled him to confirm the accounts given by the ancients of a pigmy people inhabiting the African forests. Narratives of both expeditions were published in 1861 and 1867 respectively: the former excited a warm controversy. After writing several books for the young founded upon his African adventures, M. Du Chaillu turned his attention to Northern Europe, and published in 1881 *The Land of the Midnight Sun*, and in 1889 *The Viking Age*.

**Dudley**, a municipal, county (1888) and parliamentary borough, and market-town of England, 8 miles west-north-west of Birmingham, 122 miles north-west of London, in a portion of the county of Worcester enclaved in Staffordshire. It has a joint station of the Great Western and the London and North-Western Railways, and is on the Birmingham and Stourbridge Canals. The parish church of St Thomas has been restored. The grammar school has been reorganized, and a new building with chemical laboratory was opened in 1899. Of recent erection are a technical school, free library and school of art, public baths, and an hospital for infectious diseases. Area of municipal and county borough, 3604 acres. Population (1891), 45,724; (1901), 48,809. Area of parliamentary borough, 7794 acres, of which 3615 are in Worcestershire and 4179 in Staffordshire. Included in the parliamentary borough, and $2\frac{1}{2}$ miles by rail to the south-west of Dudley, stands Brierley Hill, a market-town on the river Stour and the Stourbridge and Birmingham Canals. There is a town-hall and a free library. The industries are similar to those of Dudley—coal and iron mining, iron manufacture, engineering, &c. Area of urban district, 1023 acres; population (1881), 11,603; (1901), 12,005.

**Dudweiler**, a village of Prussia, in the Rhine province, 4 miles by rail north-east from Saarbrucken, with coal mines, ironworks, and production of fire-proof bricks. Population (1885), 11,550; (1900), 16,323.

**Duehring, Eugen Karl** (1833-——), German philosopher and political economist, was born on 12th January 1833 in Berlin. After a legal education he practised at Berlin as a lawyer till 1859. A weakness of the eyes, ending in total blindness, occasioned his taking up the studies with which his name is now connected. In 1864 he became *docent* of the University of Berlin, but, in consequence of a quarrel with the professoriate, was deprived of his licence to teach in 1874. Among his works are *Kapital und Arbeit* (1865); *Der Wert des Lebens* (1865); *Natürliche Dialektik* (1865); *Kritische Geschichte der Philosophie* (1869); *Kritische Geschichte der allgemeinen Principien der Mechanik* (1872)—one of his most successful works; *Kursus der National- und Sozialökonomie* (1873); *Kursus der Philosophie* (1875), entitled in a later edition *Wirklichkeitsphilosophie*; *Logik und Wissenschaftstheorie* (1878); *Der Ersatz der Religion durch Vollkommeneres* (1883). He published his autobiography in 1882 under the title *Sache, Leben und Feinde*; the mention of "Feinde" (enemies) is characteristic. Duehring's philosophy claims to be emphatically the philosophy of reality. He is passionate in his denunciation of everything which, like mysticism, tries to veil reality. He is almost Lucretian in his anger against religion which would withdraw the secret of the universe from our direct gaze. His "substitute for religion" is a doctrine in many points akin to Comte and Feuerbach, the former of whom he resembles in his sentimentalism. Duehring's opinions have changed considerably since his first appearance as a writer. His earlier work, *Natürliche Dialektik*, in form and matter not the worst of his writings, is entirely in the spirit of the Critical Philosophy. Later, in his movement towards Positivism, he strongly repudiates Kant's separation of phenomenon from noumenon, and affirms that our intellect is capable of grasping the whole reality. This adequacy of thought to things is due to the fact that the universe contains but one reality, *i.e.*, matter. It is to matter that we must look for the explanation both of conscious and of physical states. But matter is not, in his system, to be understood with the common meaning, but with a deeper sense as the substratum of all conscious and physical existence; and thus the laws of being are identified with the laws of thought. In this materialistic or quasi-materialistic system Duehring finds room for teleology; the end of Nature, he holds, is the production of a race of conscious beings. From his belief in teleology he is not deterred by the enigma of pain; he is a determined optimist. Pain exists to throw pleasure into conscious relief. In ethics Duehring follows Comte in

making sympathy the foundation of morality. In political philosophy he teaches an ethical communism, and attacks the Darwinian principle of struggle for existence. In economics he is best known by his vindication of the American writer H. C. Carey, who attracts him both by his theory of value, which suggests an ultimate harmony of the interests of capitalist and labourer, and also by his doctrine of "national" political economy, which advocates protection on the ground that the morals and culture of a people are promoted by having its whole system of industry complete within its own borders. His patriotism is fervent, but narrow and exclusive. He idolizes Frederick the Great, and denounces Jews, Greeks, and the cosmopolitan Goethe. Duehring's clear, incisive writing is disfigured by arrogance and ill-temper, failings which may be extenuated on the ground of his physical affliction.

**Duelling.**—While in England the law against duelling has, supported by public opinion, sufficed to condemn the practice and entirely to suppress it, a recrudescence of the custom in foreign countries, and especially in France and Germany, was observable towards the close of the 19th century. Although most penal codes make duelling an offence punishable by pains and penalties of more or less severity, no country has as yet gone so far in this direction as England, where the slayer in a duel is held to be guilty of the capital offence, and the principals and accessories, even where no fatal issue supervenes, of a misdemeanour. This survival of the trial by battle flourishes, as would be expected, in countries in which militarism reigns supreme, and where, as a corollary, the civil tribunals are supposed to furnish but inadequate guarantees for personal liberty in cases where the delicate sense of honour of the military caste is concerned. The antagonism subsisting between the combatant class and the civil population is further intensified in the "nations in arms," and notably in Germany, by the fact that an officer on retiring from the army still preserves in civil life his character as officer, and cannot seek satisfaction for personal affronts before the civil tribunals without forfeiting his position as a "man of honour." The spirit of mediævalism, which still in tradition is strong enough to support an anomaly which sober public opinion has been unable to abolish, is further fostered by the prerogative of pardon, which, except in very flagrant cases, is almost always exercised by the ruling powers in favour of the offenders.

Although French writers on the subject, notably Chateauvillard, claim for the duel a French origin, there appears to be little doubt that it was in Germany that, about the middle of the 16th century, it became established as an institution. No other country has clung to the duel with such tenacity. Academically it has found many staunch advocates among jurists in that country, and recent attempts to deal with the evil have been rather in the nature of palliatives than of measures directed towards eradicating it. Since 1896, when a tragic duel between two officers of the reserve, von Schrader and von Kotze, at Potsdam, resulting in the death of the former, more than ordinarily aroused public opinion, attempts have on various occasions been made to enlist the sympathies of the Reichstag with a view to fresh legislative enactment on the subject—but unsuccessfully. The German Emperor, in a Cabinet Order of 1897, confirmed in 1901, issued directions to the military courts of honour, insisting upon the causes of the alleged affront being in each case properly sifted, the blame brought home to the proper party, the illegality of the duel pointed out to the parties by the president of the court, and every attempt made to effect a reconciliation. It is only fair to say that where these instructions have been disregarded, rigorous punishment has not failed to be meted out to the responsible persons. The German penal code (*Reichsstrafgesetzbuch*, pars. 101–110) only punishes a duel when it is fought with lethal weapons; and much controversy has raged round the question of the *Mensuren* or students' duels (*vide infra*), which, as being conducted with sharpened rapiers, have, despite the precautions taken, in the way of bandaging the vital parts of the body which a cut could reach, to reduce the risk of a fatal issue to a minimum, been declared by the Supreme Court of the Empire to fall under the head of duels, and as such to be punishable. The so-called American duel, where the two parties draw lots, and the loser is under a moral obligation to kill himself within a specified time, is not recognized as a duel (not being a battle) by any foreign code except that of Austria (*Strafgesetzentwurf*, 1889), which makes it a penal offence "where predetermined chance shall determine which of two persons shall kill himself." The French claim for their writer Chateauvillard that he first formulated the rules of affairs of honour, and his treatise is, in effect, the accepted authority in all civilized countries. The recognized weapons are pistol, fleuret, and broadsword; and it seems to be an established rule that a civilian may, though a military man may not, refuse to fight with the sword. In July 1889 M. Freycinet (French Minister for War), in an Order addressed to the Generals commanding Army Corps, after stating that his attention had been drawn to the risk to life resulting from the use of the fleuret in military duels, communicated his decision that in the rare cases where an armed encounter was not perhaps prescribed, but authorized, by the chief of the corps, the combatants should make use, not of the fleuret, but of service swords. The German Emperor William I. also declared in favour of the broadsword; but the pistol is in Germany almost always the weapon selected. In France, unlike Germany, in which latter country military duels largely preponderate, it is parliamentarians and pressmen who mostly seek satisfaction in *affaires d'honneur*, which are often merely nominal; the weapon employed is generally the fleuret.

The Roman Catholic Church does not admit any reason justifying the duel; and it is generally understood that both Roman Catholics and Jews may, without detriment to their social position, refuse one, as being expressly prohibited by the canons of their religion. Moreover, the practice is visited by ecclesiastical censures, by excommunication, denial of the last rites of sacrament and, in the Protestant Church also, of burial by the Church.

The *Mensuren* (German students' duels) above referred to are frequently misunderstood. They bear little resemblance, save in form, to the duel *à outrance*, and should rather be considered in the light of athletic games, in which the overflow of high animal spirits in young Germany finds its outlet. These combats are indulged in principally by picked representatives of the "corps" (recognized clubs), and according to the position and value of the *Schmisse* (cuts which have landed) points are awarded to either side. Formerly these so-called duels could be openly indulged in at most universities without let or hindrance. Gradually, however, the academic authorities took cognizance of the illegality of the practice, and in many cases inflicted punishment for the offence. Nowadays, owing to the decision of the Supreme Court reserving to the common law tribunals the power to deal with such cases, the governing bodies at the universities have only a disciplinary control, which is exercised at the various seats of learning in various degrees: in some the practice is silently tolerated, or at most visited by reprimand; in others, again, by relegation or *carcer*—with the result that the students of one university

frequently visit another, in order to be able to fight out their battles under less rigorous surveillance. (P. A. A.)

**Dufaure, Jules Armand Stanislas** (1798–1881), French statesman, was born at Saujon (Charente-Inférieure) on 4th December 1798. He was called to the Bar at Bordeaux, where he won a great reputation by his oratorical gifts, but soon abandoned law for politics, and in 1834 was elected deputy. Two years later he was made *Conseiller d'État* by Thiers, but did not hold his office long. In 1839 he became Minister of Public Works in the Soult Ministry, and succeeded in freeing railway construction in France from the obstacles which till then had hampered it. Losing office in 1840, Dufaure became one of the leaders of the Opposition, and on the outbreak of the Revolution of 1848 frankly accepted the Republic, of which he remained throughout his life a foremost champion. On 13th October he became Minister of the Interior under Cavaignac, but retired on the latter's defeat in the Presidential election. During the Second Empire, Dufaure abstained from public life, and practised at the Paris bar with such success that he was elected *bâtonnier* in 1862. In 1863 he succeeded to Pasquier's seat in the French Academy. In 1871 he became a member of the Assembly, and it was on his motion that Thiers was elected President of the Republic. Dufaure received the Ministry of Justice, his tenure of which was distinguished by the passage of the jury-law. In 1873 he fell from office with Thiers, but in 1875 resumed his former post under Buffet, whom he succeeded on 9th March 1876 as President of the Council. In the same year he was elected a life senator. On 12th December he was defeated on the question of an amnesty for the Communists, but returned to power on 24th December 1877. Early in 1879 Dufaure took part in compelling the resignation of Marshal MacMahon, but immediately afterwards (1st February), worn out by factious opposition, himself laid down office. He died in Paris on 28th June 1881. (R. G.)

**Dufferin and Ava, Frederick Temple Hamilton-Temple-Blackwood,** 1st Marquis of (1826–1902), British diplomatist, son of the 4th Baron Dufferin, whom he succeeded in 1841, was born 21st June 1826, his mother, Helen Selina, being a granddaughter of Richard Brinsley Sheridan. He was educated at Eton and Oxford, and then devoted himself to his Irish estates at Clandeboye, near Belfast. He assisted in combating the Irish famine of 1846–47, and published an account of his experiences. As an Irish landlord he was generous and sympathetic, and in 1855 already advocated compensation for disturbance and for tenants' improvements; but while advocating reform, he insisted upon qualifying it by considerations of justice to the landowners. He quickly became a *persona grata* in Society and at Court; was a lord-in-waiting in 1849–50 (being created a peer of the United Kingdom in the latter year), and again in 1854–55, and was attached in 1855 to Lord John Russell's special mission to Vienna. In 1856 he made a voyage to Iceland, which he described with much humour and graphic power in his successful book, *Letters from High Latitudes*, a volume which made his reputation as a writer, though his only other purely literary publication was his memorial edition (1894) of his mother's *Poems and Verses.* Lord John Russell showed his recognition of Lord Dufferin's talents as a diplomatist by sending him in 1860 as British special commissioner in the Lebanon (Syria), where the massacres of Christians by the Mussulmans and Druses had precipitated a serious situation, which was complicated by the possibility of a French occupation. He did his work so successfully in carrying a scheme of reform that the trouble was permanently removed, and he was made a K.C.B. In 1862 he married Hariott, daughter of Captain Rowan Hamilton, of Killyleagh Castle, Down. In 1863 he was made a K.P.; and after holding the under-secretaryships for India (1864) and of war (1866), and the office of Chancellor of the Duchy of Lancaster (1868–1872), he was in 1872 appointed Governor-General of Canada. In 1871 he had been created Earl of Dufferin. In Canada his tact and personal charm were invaluable. He had already become known as a powerful and graceful speaker, and this quality was brilliantly displayed in dealing with the different Canadian nationalities, while his strictly constitutional methods enabled him to settle satisfactorily many of the problems of the new Federation. On his return he became successively ambassador at St Petersburg (1879) and at Constantinople (1881). From October 1882 to April 1883 he was employed as special British commissioner in Egypt, to clear matters up after Arabi's rebellion; but his Report, though its ability as a State paper was unimpeachable, hardly grasped the real problems of the subsequent reconstruction. In 1884 he was appointed Viceroy of India, and spent there four busy years, largely employed in restoring the equilibrium which had been upset by Lord Ripon's zeal for reform. The chief event of his administration was the annexation of Burma, which procured him the title of Marquis of Dufferin and Ava (1888); but Lady Dufferin's work on behalf of the better medical treatment of native women must also be mentioned. In 1888 he was sent as ambassador to Rome, and in 1891 to Paris, where he remained till 1896. He then retired from the public service to his Irish home. Lord Dufferin was one of the most admired men of his time. A man of well-nigh universal accomplishments, his special gift was a genius for diplomacy, his courteous and winning manner and great felicity in verbal expression being exceptionally marked. His last years were shadowed by the death of his eldest son, Lord Ava, at Ladysmith in 1899, and by financial troubles. He had become chairman of the "London and Globe Finance Corporation," which was entirely in the hands of the managing director, Mr Whitaker Wright; and when, after several warnings, the methods employed led to financial collapse, it was a matter of deep regret that Lord Dufferin should have been connected with such a business. He died on 12th February 1902, while the affairs of the company were still under investigation. (H. CH)

**Duffy, Sir Charles Gavan** (1816–——), Irish and colonial politician, was born in Monaghan, Ireland, on 12th April 1816. At an early age he became connected with the press, and was one of the founders of the *Dublin Nation* in 1842. The new journal was remarkable for its talent, for its seditious tendencies, and for the fire and spirit of its political poetry. In 1844 Duffy was included in the same indictment with O'Connell, and shared his conviction in Dublin and his acquittal by the House of Lords upon a point of law. His ideas, nevertheless, were too revolutionary for O'Connell; a schism took place in 1846, and Duffy united himself to the "Young Ireland" party. He was tried for treason-felony in 1848, but the jury were unable to agree. Duffy continued to agitate in the press and in Parliament, to which he was elected in 1852, but his failure to bring about an alliance between Catholics and Protestants upon the land question determined him in 1856 to emigrate to Victoria. There he became in 1857 Minister of Public Works, and after an active political career, in the course of which he was Prime Minister from 1871 to 1873, when he was knighted, he was elected Speaker of the House of Assembly in 1877, being made K.C.M.G. in the same year. In 1880 he resigned and returned to Europe, residing mostly in the south of France. He has published *The Ballad Poetry of Ireland* (1845),

several works on Irish history, *Conversations with Carlyle*, (1892), *Memoirs* (1898), &c. In 1891 he became first President of the Irish Literary Society. He was married three times, his third wife dying in 1889.

**Duisburg,** a town of Prussia, 15 miles by rail north from Dusseldorf, on the Ruhr-Rhine Canal and between these two rivers. The concert hall, law courts, Mercator fountain (1878), and war memorial are new. There are important iron industries, chemical works, saw-milling, shipbuilding, tobacco, cotton, sugar, soap, and other manufactures. There is also (in conjunction with Hochfeld) an extensive trade in coal. The harbour was, in 1898, entered and cleared by an aggregate of 2,745,400 tons. Population, (1885), 47,519; (1900), 92,729.

**Dulcigno** (Servian, *Ulcinj;* Turkish, *Olgun*), an ancient town formerly belonging to Turkish Albania, but since 1880 Montenegrin. The old walled quarter, with the strong castle, occupies a bold promontory on the Adriatic, 18 miles west-south-west of Scutari; the new town occupies a small narrow valley, and the little harbour is stopped with sand. There are about 5000 inhabitants. Dulcigno was the scene of a naval demonstration made by the British, Russian, French, and Italian fleets in August 1880, by which Turkey was compelled to hand the place over to Montenegro according to the Berlin Treaty.

**Dülken,** a town of Prussia, in the Rhine province, 11 miles by rail west-south-west from Crefeld, with manufactures of linen, cotton, silk, and velvet, &c., ironworks and foundries. It has a (Roman Catholic) Gothic parish church. Population (1900), 9517.

**Duluth,** capital of St Louis county, Minnesota, U.S.A., the third city in the state in population, in 46° 47′ N. lat. and 92° 06′ W. long., on the north shore of Lake Superior. The city is situated mainly on the slope of steep bluffs, which rise 600 feet above the lake level. It is regular in plan, one set of streets running directly up the bluffs, the others along their face, parallel with the lake shore; and it is well paved and sewered. A gravel spit, known as Minnesota Point, stretches nearly across Lake Superior, forming behind it a fine harbour, with a narrow entrance. Duluth is the terminus of no less than nine railways, making it, with its large lake commerce, a commercial city of the first magnitude. It handles large quantities of wheat from Red River Valley and Manitoba, estimated at 90,000,000 bushels annually, great amounts of lumber from the adjacent pine forests, and of iron ore from the Vermilion and Mesabi Ranges to the north. About 2000 vessels enter and clear annually. In 1890, its manufactures had an invested capital of $5,332,447, employed 3752 hands, and had a product valued at $8,811,723. The assessed valuation of real and personal property in 1900, on a basis of about one-half of the full value, was $24,600,333; the net debt of the city was $5,876,732; and the rate of taxation was $30 per $1000. Population (1880), 838; (1890), 33,115; (1900), 52,969, of whom 20,983 were foreign-born and 357 negroes. The death-rate in 1900 was 13·2. The village of West Duluth was included in the corporate limits in 1894.

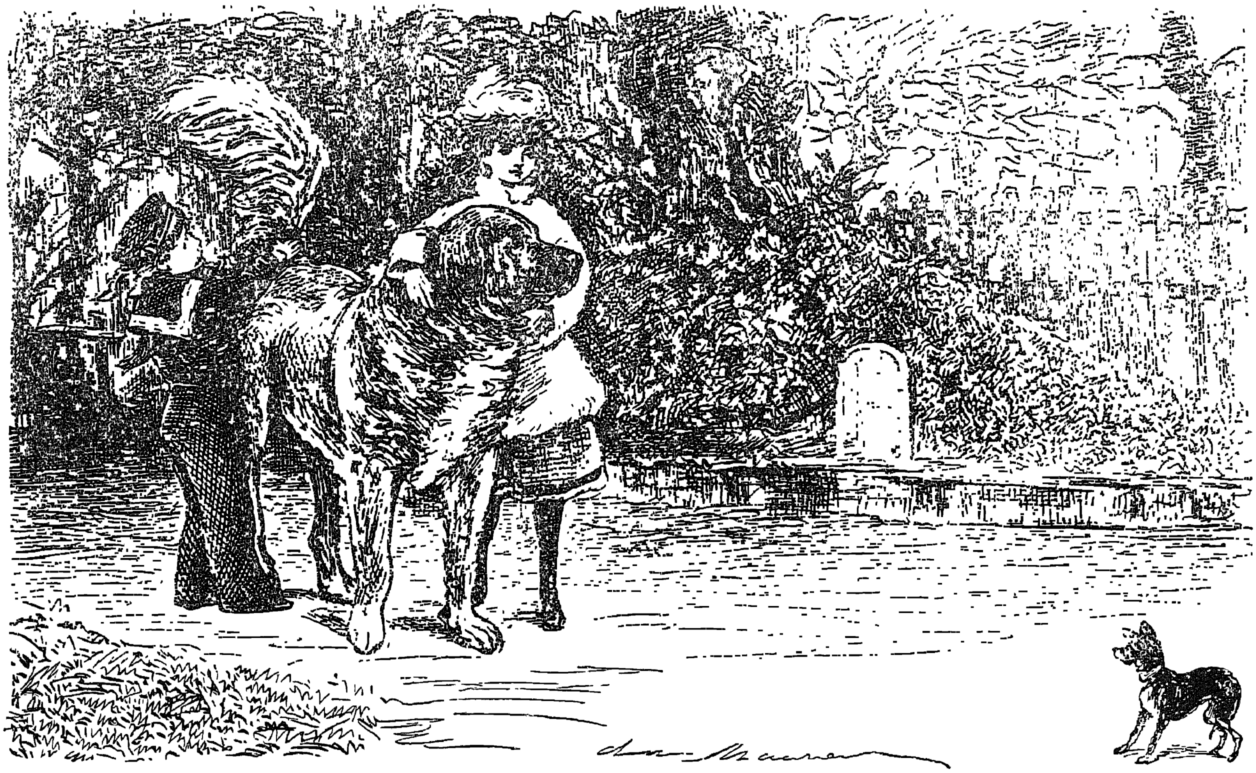
**Dulwich,** a parish of the county of London, in the metropolitan borough of Camberwell, Surrey, five miles from London Bridge, with three railway stations. The upper school, or Dulwich College, maintains its position in the front rank of English public schools. The lower, or Alleyne's school, is situated about a mile from the college, and in close proximity to it are the James Allen's school for girls and the Dulwich Presbyterian Church. There is a high school for girls within half a mile of West Dulwich station. Population (1881), 5590; (1901), 10,246.

**Dumas, Alexandre** (*fils*) (1824–1895), French dramatist and novelist, was born in Paris on the 28th July 1824. His parentage was irregular, and his father at that date still a humble clerk and not much more than a boy. "Happily," writes the son, "my mother was a good woman, and worked hard to bring me up"; while of his father he says, "by a most lucky chance he happened to be well natured," and "as soon as his first successes as a dramatist" enabled him to do so, "recognized me and gave me his name." Nevertheless the lad's earlier school-life was made bitter by his illegitimacy. The cruel taunts and malevolence of his companions rankled through life (see preface to *La Femme de Claude* and *L'Affaire Clémenceau*), and left indelible marks on his character and thoughts. Nor was his paternity, however distinguished, without peril. Alexandre the younger and elder saw life together very thoroughly, and Paris can have had few mysteries for them. Suddenly the son, who had been led to regard his prodigal father's resources as inexhaustible, was rudely undeceived. Coffers were empty, and he had accumulated debts to the amount of two thousand pounds. Thereupon he pulled himself together. To a son of Dumas the use of the pen came naturally. Like most clever young writers—and report speaks of him as specially brilliant at that time—he opened with a book of verse, *Péchés de Jeunesse* (1847). It was succeeded in 1848 by a novel, *La Dame aux Camélias*, a sort of reflection of the world in which he had been living. The book had considerable success, and was followed, in fairly quick succession, by *Le Roman d'une Femme* (1848) and *Diane de Lys* (1851). All this, however, did not deliver him from the load of debt, which, as he tells us, remained odious. In 1849 he had dramatized *La Dame aux Camélias*, but for various reasons, the rigour of the censorship being the most important, it was not till the 2nd February 1852, and then only by the intervention of Napoleon's all-powerful minister, Morny, that the play could be produced, at the Vaudeville. It succeeded then, and has held the stage ever since, less perhaps from inherent superiority to other plays which have foundered, than to the great opportunities it affords to any actress of genius. Thenceforward Dumas's career was that of a brilliant and prosperous dramatist. *Diane de Lys* (1853), *Le Demi-Monde* (1855), *La question d'argent* (1857), *Le fils naturel* (1858), *Le Père prodigue* (1859), followed rapidly. Debts became a thing of the past, and Dumas a wealthy man. The didactic habit was always strong upon him. "Alexandre loves preaching overmuch," wrote his father; and in most of his plays he assumes the attitude of a rigid and uncompromising moralist commissioned to impart to a heedless world lessons of deep import. The lessons themselves are mostly concerned with the "eternal feminine," by which Dumas was haunted, and differ in ethical value. Thus in *Les Idées de Madame Aubray* he inculcates the duty of the seducer to marry the woman he has seduced; but in *La Femme de Claude* he argues the right of the husband to take the law into his own hand and kill the wife who is unfaithful and worthless,—a thesis again defended in his novel, *L'Affaire Clémenceau*, and in his pamphlet, *L'Homme-femme;* while in *Diane de Lys* he had taught that the betrayed husband was entitled to kill—not in a duel, but summarily—the man who had taken his honour; and in *L'Etrangère* the bad husband is the victim. Nor did he preach only in his plays. He preached in voluminous introductions, and pamphlets not a few. And when, in 1870 and 1872, France was going through bitter hours of humiliation, he called her to repentance and amendment in a *Nouvelle Lettre de Junius* and two *Lettres sur les choses du jour*. As a moralist he took himself very seriously indeed. As a dramatist,

didacticism apart, he had great gifts. He knew his business thoroughly, possessed the art of situation, interest, crisis—could create characters that were real and alive. His dialogue also is admirable, the repartee rapier-like, the wit most keen. He was singularly happy, too, in his dramatic interpreters. The cast of *L'Etrangère*, for instance, comprised Sarah Bernhardt, Croizette, Madeleine Brohan, in the female characters; and Coquelin, Got, Mounet-Sully, and Fébvre in the male characters; and Desclée, whom he discovered, gave her genius to the creation of the parts of the heroine in *Une Visite de Noces*, the *Princesse Georges*, and *La Femme de Claude*. His wit has been mentioned. He possessed it in abundance, of a singularly trenchant kind. It shows itself less in his novels, which, however, do not contain his best work; but in his introductions, whether to his own books or those of his friends, and what may be called his "occasional" writings, there is an admirable brightness. At work of this kind he showed the highest literary skill. His style is that of the best French traditions. Towards his father Dumas acted a kind of brother's part, and while keeping strangely free from his literary influence, both loved and admired him. The father never belonged to the French Academy. The son was elected into that august assembly on the 30th January 1874. He died on the 27th November 1895. (F. T. M.)

**Dumas, Jean Baptiste André** (1800–1884), French chemist, was born at Alais (Gard) on 14th July 1800. Disappointed in his early hope of entering the navy, he became apprentice to an apothecary in his native town; but seeing little prospect of advancement in that calling, he soon moved to Geneva (in 1816). There he attended the lectures of such men as Pictet in physics, De la Rive in chemistry, and De Candolle in botany, and before he had reached his majority he was engaged with Prévost in original work on problems of physiological chemistry, and even of embryology. In 1823, acting on the advice of Humboldt, he left Geneva for Paris, which he made his home for the rest of his life. There he gained the acquaintance of many of the foremost scientific men of the day, and quickly made a name for himself both as a teacher and an investigator, attaining within ten years the honour of membership of the Academy of Sciences. When approaching his fiftieth year he entered political life, and became a member of the National Legislative Assembly. He acted as Minister of Agriculture and Commerce for a few months in 1850–51, and subsequently became a Senator, President of the Municipal Council of Paris, and Master of the French Mint; but his official career came to a sudden end with the fall of the Second Empire. He died at Cannes on 11th April 1884. Dumas is one of the most prominent figures in the chemical history of the middle part of the 19th century. He was one of the first to criticize the electro-chemical doctrines of Berzelius, which at the time his work began were widely accepted as the true theory of the constitution of compound bodies, and opposed a unitary view to the dualistic conception of the Swedish chemist. In a paper on the atomic theory, published so early as 1826, he anticipated to a remarkable extent some ideas which are frequently supposed to belong to a later period; and the continuation of these studies led him to the ideas about substitution ("metalepsy") which were developed about 1839 into the theory ("Older Type Theory") that in organic chemistry there are certain types which remain unchanged even when their hydrogen is replaced by an equivalent of a haloid element. Many of his well-known researches were carried out in support of these views, one of the most important being that on the action of chlorine on acetic acid to form trichloracetic acid —a derivative of essentially the same character as the acetic acid itself. In the 1826 paper he described his famous method for ascertaining vapour densities, and the redeterminations which he undertook by its aid of the atomic weights of carbon and oxygen proved the forerunners of a long series which included some thirty of the elements, the results being mostly published in 1858–60. He also devised a method of great value in the quantitative analysis of organic substances for the estimation of nitrogen, while the classification of organic compounds into homologous series was advanced as one consequence of his researches into the acids generated by the oxidation of the alcohols. Dumas was a prolific writer, and his numerous books, essays, memorial addresses, &c., show him to have been gifted with a clear and graceful style. His earliest large work was a treatise on applied chemistry in eight volumes, the first of which was published in 1828 and the last twenty years afterwards. In the *Essai de Statique Chimique des Êtres Organisés*, written jointly with Boussingault (1841), he treated the chemistry of life, both plant and animal; this book brought him into conflict with Liebig, who conceived that some of his prior work had been appropriated without due acknowledgment. In 1824, in conjunction with his friends Audouin and Adolphe Brongniart, he founded the *Annales des Sciences Naturelles*, and from 1840 he was one of the editors of the *Annales de Chimie et de Physique*. As a teacher Dumas was much sought after for his lectures at the Sorbonne and other institutions both on pure and applied science; and he was one of the first men in France to realize the importance of experimental laboratory teaching. (H. M. R.)

**Du Maurier, George Louis Palmella Busson** (1834–1896), British artist and writer, was born in Paris. His father, a naturalized British subject, was the son of *émigrés* who had left France during the Reign of Terror and settled in London. In *Peter Ibbetson*, the first of the three books which won George du Maurier late in life a reputation as novelist almost as great as he had enjoyed as artist and humorist for more than a generation, the author tells in the form of fiction the story of his singularly happy childhood. He was brought to London, indeed, when three or four years old, and spent in Devonshire Terrace and elsewhere two colourless years; but vague memories of this period were suddenly exchanged one beautiful day in June—"the first day of his conscious existence"—for the charming realities of a French garden and "an old yellow house with green shutters and mansard roofs of slate." Here, at Passy, with his "gay and jovial father" and his young English mother, the boy spent "seven years of sweet priceless home-life—seven times four changing seasons of simple genial præ-Imperial Frenchness." The second chapter of Du Maurier's life had for scene a Paris school, very much in the style of that "Institution F. Brossard" which he describes, at once so vividly and so sympathetically, in *The Martian*; and like "Barty Josselin's" schoolfellow and biographer, he left it (in 1851) to study chemistry at University College, London, actually setting up as an analytical chemist afterwards in Bucklersbury. But this was clearly not to be his *métier*, and the year 1856 found him once more in Paris, in the Quartier Latin this time, in the core of that art-world of which in *Trilby*, forty years later, he was to produce with pen and pencil so idealistic and fascinating a picture. Then, like "Barty Josselin" himself, he spent some years in Belgium and the Netherlands, experiencing at Antwerp in 1857, when he was working in the studio of Van Lerius, the one great misfortune of his life—the gradual loss of sight in his left eye, accompanied by alarming symptoms in his right. It was a period of



**CONFUSION OF CAUSE AND EFFECT.**

*Maggie.* "Oh, Tommy! ! look at that *sweet* little Thing ! ! ! I'm afraid it's afraid of *Chimborazo!* Just wag *Chimborazo's* Tail, to put him in a good Temper, there's a good Boy!"

(*By permission of the Proprietors of "Punch."*)

tragic anxiety, for it seemed possible that the right eye might also become affected; but this did not happen, and the dismal cloud was soon to show its silver lining, for, about Christmas time 1858, there came to the forlorn invalid a copy of *Punch's Almanac*, and with it the dawn of a new era in his career.

There can be little doubt that the study of this *Almanac*, and especially of Leech's drawings in it, fired him with the ambition of making his name as a graphic humorist; and it was not long after his return to London in 1860 that he sent in his first contribution (very much in Leech's manner) to *Punch*. Mark Lemon, then editor, appreciated his talent, and on Leech's death in 1865 appointed him his successor, counselling him with wise discrimination not to try to be "too funny," but "to undertake the light and graceful business" and be the "romantic tenor" in Mr Punch's little company, while Keene, as Du Maurier puts it, "with his magnificent highly trained basso, sang the comic songs." These respective *rôles* the two artists continued to play until the end, seldom trespassing on each other's province; the "comic songs" finding their inspiration principally in the life of the homely middle and lower middle classes, while the "light and graceful business" enacted itself almost exclusively in "good Society." To a great extent, also, Du Maurier had to leave outdoor life to Keene, his weak sight making it difficult for him to study and sketch in the open air and sunshine, thus cutting him off, as he records regretfully, from "so much that is so popular, delightful, and exhilarating in English country life"—hunting and shooting and fishing and the like. He contrived, however, to give due attention to milder forms of outdoor recreation, and turned to good account his familiarity with Hampstead Heath and Rotten Row, and his holidays with his family at Whitby and Scarborough, Boulogne and Dieppe.

Of Du Maurier's life during the thirty-six years of his connexion with *Punch* there is not, apart from his work as an artist, much to record. In the early 'sixties he lived at 85 Newman Street in lodgings, which he shared with his friend Lionel Henley, afterwards R.B.A., working hard at his *Punch* sketches and his more serious contributions to *Once a Week* and the *Cornhill Magazine*. After his marriage with Miss Emma Wightwick in 1862 he took a spacious and pleasant house near Hampstead Heath, in surroundings made familiar in his drawings. Shortly before he died he moved to a house in Oxford Square. About 1866 he struck out a new line in his admirable illustrations to Jerrold's *Story of a Feather*. In 1869 he realized a long-cherished aspiration, the illustrating of Thackeray's *Esmond*, and in 1879 he drew twelve additional vignettes for it, in the same year providing several illustrations for the *Ballads*. From time to time he sent pretty and graceful pictures to the exhibitions of the Royal Society of Painters in Water-Colour, to which he was elected in 1881. In 1885 the first exhibition of his works at the Fine Art Society took place. Thus occupied in the practice of his art, spending his leisure in social intercourse with his many friends and at home with his growing family, hearing all the new singers and musicians, seeing all the new plays, he lived the happiest of lives. He died somewhat suddenly on 8th October 1896, and was buried in the Hampstead Cemetery.

It is impossible, in considering Du Maurier's work, to avoid comparing it with that of Leech and Keene, the more so that in his little book on *Social Pictorial Satire* he himself has set forth or suggested the points both of resemblance and of difference. Like Keene, though Keene's marvellous technique was his despair, Du Maurier was a much more finished draughtsman than John Leech, but in other respects he had less in common with the younger than with the older humorist. He shows himself, in the best sense, a man of feeling in all his work. He is clearly himself in love with "his pretty woman," as he calls her—every pen-stroke in his presentment of her is a caress. How affectionate, too, are his renderings of his fond young mothers and their big, handsome, simple-minded husbands; his comely children and neat nurserymaids; even his dogs—his elongated dachshunds and magnificent St Bernards! And how he scorns the snobs and philistines—Sir Gorgius Midas and Sir Pompey Bedell, Grigsby and Cadby, Soapley and Toadson! How merciless is his ridicule of the æsthetes of the 'eighties—Maudle and Postlethwaite and Mrs Cimabue Brown! Even to Mrs Ponsonby de Tomkyns, his most conspicuous creation, his satire is scarcely tempered, despite her prettiness. He shows up unsparingly all her unscrupulous little ways, all her cynical, cunning little wiles. Like Leech, he revelled in the lighter aspects of life—the humours of the nursery, the drawing-room, the club, the gaieties of the country house and the seaside—without being blind to the tragic and dramatic. Just as Leech could rise to the height of the famous cartoon "General Février turned Traitor," so it was Du Maurier who inspired Tenniel in that impressive drawing on the eve of the Franco-Prussian War, in which the shade of the great Napoleon is seen warning back the infatuated Emperor from his ill-omened enterprise. In his tender drawings in *Once a Week*, also, and in his occasional excursions into the grotesque in *Punch*, such as his picture of "Old Nickotin stealing away the brains of his devotees," he has given ample proof of his faculty for moving and impressive art. The technique of Du Maurier's work in the 'eighties and the 'nineties, though to the average man it seems a marvel of finish and dexterity, is considered by artists a falling off from what was displayed in some of his earlier *Punch* drawings, and especially in his contributions to the *Cornhill Magazine* and *Once a Week*. His later work is undoubtedly more mannered, more "finicking," less simple, less broadly effective. But it is to his fellow-craftsmen only and to experts that this is noticeable.

A quaint tribute has been paid to the literary talent shown in Du Maurier's inscriptions to his drawings, by Mr F. Anstey, his colleague on the staff of *Punch*. "In these lines of letterpress," says Mr Anstey, "he has brought the art of précis-writing to perfection." They are indeed singularly concise and to the point. It is the more curious, therefore, to note that in his novels, and even in his critical essays, Du Maurier reveals very different qualities: the précis-writer has become an *improvisatore*, pouring out his stories and ideas in full flood, his style changing with every mood—by turn humorous, eloquent, tender, gay, sometimes merely "skittish," sometimes quite solemn, but never for long; sometimes, again, breaking into graceful and haunting verse. He writes with apparent artlessness; but, in his novels at least, on closer examination, it is found that he has in fact exerted all his ingenuity to give them—what such flagrantly untrue tales most require—verisimilitude. It is hard to say which of the three stories is the more impossible: that of Trilby, the tone-deaf artist's model who becomes a *prima donna*, that of Barty Josselin and his guardian angel from Mars, or that of the dream-existence of Peter Ibbetson and the Duchess of Towers. They are all equally preposterous, and yet plausible. The drawings are cunningly made to serve the purpose of evidence, circumstantial and direct. These books cannot be criticized by the ordinary canons of the art of fiction. They are a *genre* by themselves, a blend of unfettered day-dream and rose-coloured reminiscence.

For the dramatic version of *Trilby* by Mr Paul Potter Du Maurier would accept no credit. The play was pro-

duced in 1895 by Mr Beerbohm Tree, at the Haymarket, with immense popular success.

Some striking examples of Du Maurier's work for *Once a Week* and the *Cornhill Magazine* are included in Gleeson White's *English Illustrators of the Sixties*. The following is a list of the chief works which he illustrated: Foxe's *Book of Martyrs*, 1865; Mrs Gaskell's *Wives and Daughters*, 1866; Jerrold's *Story of a Feather*, 1867; Owen Meredith's *Lucile*, 1868; *The Book of Drawing-room Plays*, by H. Dalton, 1868; *Sooner or Later*, by C. A. G. Brooke, 1868; Thackeray's *Esmond*, 1869 and 1879, and *Ballads*, 1879; *Misunderstood*, by Florence Montgomery, 1874; *Round about the Islands*, by C. W. Scott, 1874; *Hurlock Chase*, by G. E. Sargent, 1876; *Songs of many Seasons*, by J. Browne (in collaboration), 1876; *Pegasus Re-saddled*, by H. C. Pennell, 1877; *Ingoldsby Legends* (in collaboration), by R. Barham, 1877; *Prudence*, by L. C. Lillie, 1882; *As in a Looking-glass*, by F. C. Phillips, 1889; *Luke Ashleigh*, by A. Elwes, 1891; and his own three novels, which appeared serially in *Harper's Magazine*: *Peter Ibbetson*, 1892; *Trilby*, 1894; *The Martian*, 1897, and published after his death. In 1897 also there was published, under the title *English Society*, with an introduction by W. D. Howells, a collection of full-page drawings which he had contributed regularly to *Harper's Magazine*.

Some of his *Punch* drawings have been reproduced also in *The Collections of Mr Punch*, 1880; *Society Pictures from Punch*, 1890; *A Legend of Camelot*, 1890. To his *Social Pictorial Satire* (1890) reference has been made. He contributed two essays upon book illustration to the *Magazine of Art*, 1890. See also the *Magazine of Art* for 1892, for an article upon his work by W. Delaplaine Scull, with illustrations. Other volumes containing information about his life and work are: *The History of Punch*, by M. H. Spielmann; *In Bohemia with Du Maurier*, by Felix Moscheles; Henry James's "Du Maurier and London Society," *Century Magazine*, 1883; and "Du Maurier," *Harper's Magazine*, September 1897, June 1899. See also Ruskin's *Art of England*, Lecture 5, Pennell's *Pen-Drawing and Pen-Draughtsmen*, and Muther's *Modern Painting*, vol. ii. (F. W. W.)

**Dumbarton,** a seaport, royal and parliamentary burgh (Kilmarnock group), and the county town of Dumbartonshire, on the river Leven near its confluence with the Clyde, 16 miles west by north of Glasgow by rail. A large park, Levengrove, was presented in 1885, and there is a public common and recreation ground. The burgh hall and academy were restored after a fire in 1883. There are two cottage hospitals and a philosophical and literary institute, whilst recent erections are a Congregational church, a Denny Memorial Institute, new county buildings, new municipal buildings, and a combination hospital for infectious diseases. There are two large shipbuilding yards, and numerous industries connected with shipbuilding. The output was 37,734 tons in 1889, and 52,623 tons in 1899; and in the latter year a marine engineering work turned out 16 sets of marine engines, aggregating 35,700 i.h.p. Only a few married artillerymen now occupy the ancient castle. There is an academy under the School Board. Population of parliamentary burgh (1881), 13,782; (1901), 19,864.

**Dumbartonshire,** a western county of Scotland, bounded S. by the Clyde river and firth, E. by Stirlingshire and Lanarkshire, N. by Perthshire, and W. by Loch Long and Argyllshire.

*Area and Population.*—The Stirling part of the parish of New Kilpatrick, including the town of Milngavie, was transferred to Dumbartonshire in 1891. According to the latest official estimate, the area of the county (foreshore excluded) is 170,762 acres, or 267 square miles. The population was in 1881, 75,333; in 1891, 94,495; in 1891, on the above area, 98,014, of whom 46,683 were males and 49,331 females; in 1901, 113,870. On the old area, taking land only (154,542 acres, or 241·5 square miles), the number of persons to the square mile in 1891 was 383, and the number of acres to the person 1·6. In the registration county the population increased between 1881 and 1891 by 25·4 per cent. Between 1881 and 1891 the excess of births over deaths was 13,252, and the increase of the resident population 19,832. The following table gives particulars of births, deaths, and marriages in 1880, 1890, and 1899:—

| Year. | Deaths. | Marriages. | Births. | Percentage of Illegitimate. |
|---|---|---|---|---|
| 1880 | 1500 | 475 | 2513 | 5.0 |
| 1890 | 1883 | 583 | 3065 | 4·50 |
| 1899 | 1872 | 676 | 3511 | 3·4 |

The birth-rate is above, the death-rate and marriage-rate are both below, the rates for Scotland. The following table gives the birth-rate, death-rate, and marriage-rate per thousand of the population for a series of years:—

| | 1880. | 1881–90. | 1890. | 1891–98. | 1899. |
|---|---|---|---|---|---|
| Birth-rate . . | 32·73 | 33·02 | 31·79 | 30·93 | 29·84 |
| Death-rate . . | 19·54 | 17·98 | 19·53 | 17·29 | 15·90 |
| Marriage-rate . | 6·19 | 5·91 | 6·04 | 5·46 | 5·74 |

At the census of 1891 there were 3618 persons in Dumbartonshire who spoke Gaelic, and of these 37 spoke Gaelic only; and there were 74 foreigners. Valuation in 1889–90, £459,141; in 1899–1900, £685,389.

*Administration.*—The county returns a member to Parliament. Dumbarton (19,864), the county town, is the only royal burgh, and belongs to the Kilmarnock group of parliamentary burghs. The county contains among its police burghs Helensburgh (8554), Kirkintilloch (10,502), and Clydebank (18,654), and considerable manufacturing towns are Alexandria (8392) and Renton (5227). There are 12 civil parishes, most of which belong to the Dumbarton combination, with a poorhouse at the county town. The number of paupers and dependants in September 1899 was 2155. Dumbarton forms a sheriffdom with Stirling and Clackmannan, and there is a resident sheriff-substitute at Dumbarton, who sits also at Kirkintilloch.

*Education.*—Fourteen school boards manage 47 schools, which had an average attendance of 16,100 in 1899–1900; while 9 voluntary schools, of which 7 are Roman Catholic and 1 Episcopal, had 2956. The whole of the county "residue" grant and a trifling proportion of that accruing to the burghs is spent in subsidizing science, art, and technical classes (including building and mechanical construction), in supporting agricultural lectures, and in paying the fees and travelling expenses of county students at the Glasgow Technical College.

*Agriculture.*—The percentage of cultivated area in 1898 was 30·2. In 1895 there were 8772 acres under wood. Of the 667 holdings in 1895, the date of the latest return, the average size was 76 acres. The percentage under 5 acres was 15·89, between 5 and 50 acres 35·08, and over 50 acres 49·03. The number of farms between 50 and 100 acres was 117; between 100 and 300, 198; and there were only 12 over 300. The proximity of the county to Glasgow encourages high farming. Dairying is carried on on a considerable scale. Highland cattle are bred on the upland farms. The following table gives the principal acreages at intervals of five years from 1880:—

| Year. | Area under Crops. | Corn Crops. | Green Crops. | Clover. | Permanent Pasture. | Fallow. |
|---|---|---|---|---|---|---|
| 1880 | 46,432 | 10,037 | 5000 | 13,010 | 18,269 | 98 |
| 1885 | 47,305 | 9,313 | 4249 | 15,482 | 18,113 | 148 |
| 1890 | 48,367 | 8,226 | 3994 | 18,341 | 17,632 | 114 |
| 1895 | 50,813 | 8,221 | 4050 | 14,822 | 23,522 | 127 |
| 1899 | 51,426 | 8,284 | 4164 | 16,416 | 22,432 | 67 |

The following table gives particulars of the live stock during the same years:—

| Year. | Total Horses. | Total Cattle. | Cows or Heifers in Milk or Calf. | Sheep. | Pigs. |
|---|---|---|---|---|---|
| 1880 | 1865 | 12,538 | 6676 | 73,596 | 697 |
| 1885 | 1730 | 14,112 | 7491 | 70,735 | 953 |
| 1890 | 1745 | 14,990 | 7601 | 73,946 | 1083 |
| 1895 | 2072 | 14,676 | 8203 | 75,032 | 1837 |
| 1899 | 1845 | 15,384 | 8660 | 76,287 | 1339 |

In 1891, 2491 men and 398 women were returned as being engaged in agriculture.

*Industries and Trade.*—Turkey-red dying is now the most distinctive industry; indeed, the Vale of Leven is the headquarters of this industry in Scotland. Clydebank (*q.v.*) has become an important shipbuilding and engineering centre. Among other industries of the county now of importance, noticed under Dumbarton, Kirkintilloch, Alexandria, Duntocher, &c., are distilling, the manufacture of chemicals, paper-making, and muslin-weaving. 339,559 tons of coal were raised in 1890, valued at £135,824; 511,199 tons, valued at £208,740, in 1899. Of ironstone, 107,767

tons, valued at £58,272, were obtained in 1890; 38,722 tons, valued at £20,329, in 1899. In 1899 were also obtained 29,585 tons of fireclay, 30,355 tons of sandstone, and 11,398 tons of limestone.

In 1891 the number of persons in the county engaged in industrial pursuits was 23,258 men and 7030 women, of whom 2967 men were concerned with machines and implements, 2746 men with ships, 3305 men and 2030 women with textiles, and 5782 men with minerals. Fishing is carried on on a small scale at Helensburgh and along the Gareloch, and salmon fishing at Dumbarton. About 42 miles have been added to the railway mileage during the past twenty-five years, the largest contributor being the West Highland Railway (1894).

**Dumfries,** a royal and parliamentary burgh (Dumfries group), railway station, and county town of Dumfriesshire, Scotland, on the left bank of the river Nith. The town is half industrial, half residential. The station has been largely rebuilt, and recent erections are a new post office, St George's Hall, a volunteer drill hall, a contagious diseases hospital, a new academy (£20,000), and a Crichton Institution chapel (£30,000). The corporation purchased the gasworks in 1878, and has rebuilt and enlarged them. Public baths and wash-houses were presented to the town in 1898, and a marble statue of Burns was unveiled in 1882. A free library is under construction. The School Board controls an endowed academy. A novitiate has lately been added to the Commercial College of the Marist Brotherhood. Population of royal burgh (1881), 15,759; (1891), 16,675; of parliamentary burgh (1891), 18,049; (1901), 17,081. MAXWELLTOWN, on the other side of the river, and in Kirkcudbrightshire, but included in the parliamentary burgh of Dumfries, is a burgh of barony and a police burgh. The new bridge connecting the towns has been widened. There are in Maxwelltown 2 tweed mills, 3 hosiery factories, and dye-works. Recent erections are a Roman Catholic church and convent, an Episcopal mission church, a court house, and a new prison for Dumfries. Population (1891), 4975; (1901), 5789.

**Dumfriesshire,** a border county of Scotland, bounded S. by the Solway Firth, N. by Lanark, Peebles, and Selkirk, W. by Ayr and Kirkcudbright, and S. by Cumberland.

*Area and Population.*—In 1891 the Lanark parts of the parishes of Moffat and Kirkpatrick-Juxta were transferred to Dumfriesshire. The area of the county, according to the latest official estimate, is 688,057 acres, or 1068·8 square miles. The population was in 1881, 74,808; in 1891, 74,221; in 1891, on the above area, 72,245, of whom 34,898 were males and 39,347 females; in 1901, 72,569. On the old area, taking land only (680,217 acres or 1062·8 square miles), the number of persons to the square mile in 1891 was 70, and the number of acres to the person 9·2. In the registration county the population decreased 2·5 per cent. between 1881 and 1891. Between 1881 and 1891 the excess of births over deaths was 7053, and the decrease of the resident population 1922. The following table gives particulars of births, deaths, and marriages in 1880, 1890, and 1899:—

| Year. | Deaths. | Marriages. | Births. | Percentage of Illegitimate. |
|---|---|---|---|---|
| 1880 | 1417 | 469 | 2252 | 14·4 |
| 1890 | 1469 | 486 | 1962 | 13·46 |
| 1899 | 1255 | 482 | 1835 | 10·8 |

The following table gives the birth-rate, death-rate, and marriage-rate per thousand of the population for a series of years:—

| | 1880. | 1881-90. | 1890. | 1891-98. | 1899. |
|---|---|---|---|---|---|
| Birth-rate | 29·60 | 28·51 | 26·37 | 26·16 | 25·33 |
| Death-rate | 18·63 | 19·13 | 19·74 | 19·22 | 17·32 |
| Marriage-rate | 6·17 | 6·14 | 6·53 | 6·32 | 6·65 |

In 1891 there were 201 Gaelic-speaking persons in the county, and 75 foreigners. Valuation in 1889-90, £623,427; 1899-1900, £629,765.

*Administration.*—The county returns a member to Parliament. Royal burghs are Dumfries (17,081), Annan (5804), Lochmaben (1328), and Sanquhar (1379), which all belong to the Dumfries group of parliamentary burghs. Langholm (3142) is the largest police burgh. There are 43 civil parishes, and 2 poorhouses, besides the one at Dumfries; the number of paupers and dependants in September 1899 was 1547. Dumfries forms a sheriffdom with Kirkcudbright and Wigtownshire, and there is a resident sheriff-substitute at Dumfries, who sits also at Annan, Langholm, and Lockerbie.

*Education.*—Forty-five school boards manage 92 schools, which had an average attendance of 10,418 in 1898-99, while 13 voluntary schools (2 Roman Catholic and 1 Episcopal) had an attendance of 1624. There are academies at Dumfries, Closeburn, Annan, Langholm, and Moffat, and Dryfesdale public school and others earned grants in 1898-99 for giving higher education. The county council and most of the burgh councils hand over the bulk of the "residue" grant to the County Committee on Secondary Education, which expended in 1899 £1076 of parliamentary grant, and £1356 thus contributed on building grants, apparatus, subsidies to higher schools, bursaries, and science and technical classes, embracing agriculture, dairying (at Kilmarnock Dairy School), and practical chemistry.

*Agriculture.*—The percentage of cultivated area was 37·6 in 1898; 31,531 acres were under wood in 1895, 1311 having been planted since 1881. Wheat is a steadily diminishing crop, and the oats acreage, which was 48,292 in 1871, was 43,937 in 1898. The following table gives the principal acreages at intervals of five years from 1880:—

| Year. | Area under Crops. | Corn Crops. | Green Crops. | Clover. | Permanent Pasture. | Fallow. |
|---|---|---|---|---|---|---|
| 1880 | 231,447 | 50,406 | 25,783 | 71,450 | 83,221 | 587 |
| 1885 | 238,158 | 49,708 | 25,331 | 69,294 | 93,535 | 290 |
| 1890 | 249,168 | 48,557 | 25,978 | 76,306 | 98,145 | 130 |
| 1895 | 259,082 | 46,495 | 24,996 | 82,797 | 104,374 | 344 |
| 1899 | 259,764 | 44,414 | 23,551 | 80,838 | 110,790 | 106 |

The following table gives particulars of the live stock during the same years:—

| Year. | Total Horses. | Total Cattle. | Cows or Heifers in Milk or Calf. | Sheep. | Pigs. |
|---|---|---|---|---|---|
| 1880 | 7414 | 55,576 | 16,266 | 517,288 | 10,286 |
| 1885 | 7240 | 57,119 | 18,677 | 490,641 | 12,154 |
| 1890 | 7409 | 58,211 | 18,420 | 527,319 | 14,034 |
| 1895 | 7990 | 58,067 | 19,489 | 525,301 | 11,531 |
| 1899 | 7484 | 62,016 | 20,339 | 565,490 | 10,915 |

Pig-feeding has fallen off steadily since the value of the pork product reached £100,000 in 1867. Arable farms range from 100 to 300 acres, and pastoral from 300 to 3000. At the date of the last return, 1895, the average size of the 2785 holdings was 93 acres; 21·83 were under 5 acres, 30·41 between 5 and 50, and 47·76 over 50 acres. The number of farms between 50 and 100 acres was 384; between 100 and 300, 763; between 300 and 500, 147; between 500 and 1000, 34; and there were 2 over 1000 acres. The fortunes of agriculture of recent years have not tended to deprive the county of its general pastoral appearance. At the census of 1891 there were 7122 men and 1089 women engaged in agriculture.

*Industries and Trade.*—The following table shows the output of minerals for 1890 and 1899; the figures for coal represent the output of Dumfries and Argyll shires conjointly:—

| Year. | Coal. | | Lead Ore. | | Sandstone. | |
|---|---|---|---|---|---|---|
| | Tons. | Value. | Tons. | Value. | Tons. | Value. |
| 1890 | 106,128 | £38,471 | 1863 | £12,973 | ... | ... |
| 1899 | 154,786 | £58,690 | 1848 | £14,500 | 245,912 | £83,039 |

The number of persons engaged in industrial pursuits in 1891 was 9754 men and 3535 women, of whom 2047 men were connected with minerals, and 1192 men and 1308 women with textiles. Dumfries and Annan (*q.v.*) are the ports. Only 2 miles have been added to the railway mileage during the past twenty-

five years, but a light railway (16 miles) from Dumfries to Moniaive has been sanctioned.

**Dünaburg.** See DVINSK.

**Dunbar,** a royal burgh and seaport of Haddingtonshire, Scotland, near the mouth of the Firth of Forth, 28 miles east of Edinburgh by rail. It is a sub-port of Leith, but owing to the advent of steam the shipping is now extinct. The Victoria Harbour (£20,000) is a refuge for vessels between Leith Roads and the Tyne. The fishing industry has declined. Shipbuilding and paper-making are no longer carried on, but the manufacture of agricultural implements is considerable, and there is a considerable export trade in potatoes. The town is a rising watering-place. Episcopal and Roman Catholic churches have been built. Dunbar was formerly one of the Haddington group of burghs, but its constituency was merged in that of the county in 1885. Population (1881), 3545; (1901), 3581.

**Dunblane,** a market town and police burgh of Perthshire, Scotland, on the river Allan, 5 miles north-west of Stirling by rail. A masonic hall was erected in 1886 and a town hall in 1887. The mineral springs at Cromlix are included within the beautiful grounds—18 acres in extent—of the hydropathic establishment, which cost over £60,000. The cathedral underwent restoration, 1892–95, at a cost of £26,000. Population of police burgh (1881), 2186; (1901), 2516.

**Duncker, Maximilian Wolfgang** (1811–1886), German historian and politician, eldest son of the publisher Karl Duncker, was born at Berlin on 15th October 1811. He studied at the Universities of Bonn and Berlin till 1834, was then accused of participation in the students' societies, which the Government was endeavouring to suppress, and was condemned to six years' imprisonment, afterwards reduced to six months. He had already begun his labours as a historian, but after serving his sentence in 1837, found himself debarred till 1839 from completing his course at Halle, where in 1842 he obtained a professorship. Elected to the National Assembly at Frankfort in 1848, he joined the Right Centre party, and was chosen reporter of the projected constitution. He sat in the Erfurt Assembly of 1850, and in the second Prussian Chamber from 1849 to 1852. During the crisis in Schleswig and Holstein in 1850 he endeavoured in person to aid the Duchies in their struggles. An outspoken opponent of the policy of Manteuffel, he was refused promotion by the Prussian Government, and in 1857 accepted the professorship of history at Tübingen. In 1859, however, he was recalled to Berlin as assistant in the Ministry of State in the Auerswald Cabinet, and in 1861 was appointed Councillor to the Crown Prince. In 1867 he became Director of the Prussian Archives, with which it was his task to incorporate those of Hanover, Hesse, and Nassau. He retired on 1st January 1875, and died at Ansbach on 21st July 1886. Duncker's eminent position among German historians rests mainly on his *Geschichte des Alterthums* (1st ed., 1852–57; 5th ed., in 9 vols., 1878–86; English translation by Evelyn Abbott, 1877–82). He edited, with J. G. Droysen, *Preussische Staatsschriften, Politische Correspondenz Friedrichs des Grossen,* and *Urkunden und Actenstücke zur Geschichte des Kurfursten Friedrich Wilhelm von Brandenburg.* To the period of his political activity belong, *Zur Geschichte der deutschen Reichsversammlung in Frankfurt* (1849); *Heinrich von Gagern* (1850), in the series of *Männer der Gegenwart;* and the anonymous *Vier Monate auswärtiger Politik* (1851). His other works include *Origines Germanicæ* (1840); the lectures *Die Krisis der Reformation* (1845) and *Feudalität und Aristokratie* (1858); *Aus der Zeit Friedrichs des Grossen und Friedrich Wilhelms III. Abhandlungen zur preussischen Geschichte* (1876); followed after his death by *Abhandlungen aus der griechischen Geschichte* and *Abhandlungen aus der neueren Geschichte* (1887). (H. SY)

**Dundalk,** a seaport, urban sanitary district, and formerly (until 1885) a parliamentary borough in the county of Louth, Ireland, on Dundalk Bay, 50 miles north of Dublin. It is a large railway centre, being in communication with Belfast, Dublin, Londonderry, and *viâ* Clones with the western counties. There are also branch lines to Ardee and Greenore, from which there is a service of steam packets to Holyhead. Steamers leave for Liverpool several times a week, carrying large quantities of farm produce and live stock. In all, 833 vessels of 111,374 tons entered in 1899, and 426 of 72,684 tons cleared. The number of vessels registered in the fishery district in 1899 was 191, employing 689 men and boys. Population (1881), 11,913; (1901), 13,067.

**Dundee,** a seaport, royal and parliamentary burgh (returning two members), and county of a city (1894), Forfarshire, Scotland, on the north bank of the Firth of Tay, 59 miles north-north-east of Edinburgh by rail. Its area is 4201 acres. Jute has displaced linen as the principal manufacture of the city, and gives employment to 30,000 hands, flax employing about 10,000. The total annual value of the product of jute goods is estimated at £3,800,000, and of linen goods at £450,000. The following table shows the imports of raw materials and the exports of manufactured articles for 1890, 1895, and 1899:—

<table>

</table>

The Arctic seal and whale fishing employed 6 vessels in 1898. The total expenditure on the harbour, with its $36\frac{1}{4}$ acres of wet docks and tidal basin, was £1,088,620 up to 1898, and the debt was then £386,883, including £20,000 for the Tay ferries, which were taken over by the Harbour Trust in 1890, and on which £58,465 has since been expended. In 1891 the revenue of the harbour was £62,829, and in 1898 £60,636. In 1888, 1244 vessels of 520,363

tons entered the port, and 774 vessels of 341,192 tons cleared; in 1898, 1497 vessels of 661,264 tons entered, and 1417 of 729,067 tons cleared. The registered shipping at the port at the close of 1898 was 140 vessels of 109,073 tons. In 1889, 14 vessels of 18,311 tons were launched from the shipbuilding yards; and in 1899, 19 vessels of 17,908 tons. Recent erections are the Victoria Art Galleries, the Victoria Hospital for Incurables, the Maternity Hospital and Nurses' Home, infectious diseases hospital, small-pox hospital, royal lunatic asylum, and bronze statues of Queen Victoria (1899) and Burns (1880). Lochee Park (25 acres) and Fairmuir (12 acres) were presented to the town in 1883 and 1890. Dundee Law has been acquired by the corporation, and the Barrack Park was bought in 1893 for £40,000. The esplanade on the river frontage was extended in 1893 to a total length of $2\frac{1}{2}$ miles; and about 130 acres of additional recreation ground are about to be reclaimed from the river, as a result of which the esplanade will be extended another half mile. A large part of the town has been reconstructed of late years, under an Improvement Act, at a total cost of about half a million sterling; and another scheme of reconstruction is in progress, which will cost a further sum of £350,000. There are 18 Established churches, 32 United Free, 8 Congregational, 5 Scottish Episcopal, 5 Roman Catholic, 2 Wesleyan, and 6 belonging to other denominations. Dundee University College was founded in 1881 by Dr and Miss Baxter, and has now endowments amounting to £224,027. The college has, after much litigation, been incorporated with the University of St Andrews, and has a staff of principal, 13 professors, and numerous lecturers in arts, science, medicine, and law. Evening classes form an important part of the teaching scheme, and a training college for teachers has just been inaugurated. There are also a technical institute, two endowed high schools—one for boys and the other for girls—and 35 elementary schools. The two academies and 21 of the elementary schools are managed by the School Board, and have an average attendance of 17,553; while the other 14 schools, of which 6 are Roman Catholic and 4 Episcopal, have an average attendance of 5176. On board a training-ship, which lies in the Tay, there are about 400 boys, one-fourth of whom belong to Dundee. Valuation in 1889–90, £640,225; 1899–1900, £829,388. Population (1881), 140,794; (1891), 154,118; (1901), 160,871.

**Dunedin,** the third largest city of New Zealand, with (1901) 53,294 inhabitants, not including 2205 persons in the borough of Port Chalmers, eight miles distant, on the same harbour. The former prosperity of Dunedin has lately revived, owing in part to gold-dredging in the Otago rivers. The University College includes a School of Medicine and Medical Museum, and a School of Mines. The University library contains 5000 works of reference, well selected. The primary and secondary schools of the town are excellent. Four hundred and two pupils attend the School of Art, and there is a small training college for state teachers. Dunedin is well built and well administered. The total import and export trade was £2,721,577 in 1893; £4,423,442 in 1899; and £3,636,248 in 1900. The headquarters of the Union Steamship Company of New Zealand are in Dunedin.

**Dunfermline,** a royal, parliamentary (Stirling and Dunfermline group), and police burgh and city of Fifeshire, Scotland, $5\frac{1}{2}$ miles north of the Forth Bridge by rail. The new corporation buildings were completed in 1879 and cost £25,000; other erections have been a public hall, a Carnegie free library, and new buildings for the high school. Population of the royal and police burgh (1881), 19,915; (1901), 25,250.

**Dungannon,** an inland town and urban sanitary district in the county of Tyrone, Ireland, $94\frac{1}{2}$ miles north-north-west of Dublin by rail. It ceased to be a parliamentary borough in 1885. Population (1881), 4084; (1901), 3693.

**Dungarpur,** a native state of India, in the Rajputana Agency, in the extreme south of Rajputana. A large portion is hilly, and inhabited by Bhils. Its area is 1440 square miles. The population in 1881 was 86,429; in 1891 it was 165,400, including 66,952 Bhils, who were not enumerated in 1881, giving an average density of 115 persons per square mile. In 1901 the total population was 100,018, showing an apparent decrease of 40 per cent., due to the famine of 1899–1900. The revenue in 1896–97 was Rs.2,21,297, and the tribute was Rs.34,147. An annual fair is held at Baneswar, where goods are sold to the value of Rs.2,50,000, chiefly cloth. Kherwara is the headquarters of the Meywar Bhil corps.

**Dungarvan,** a maritime town and urban sanitary district in the county of Waterford, Ireland, 125 miles south-west of Dublin by rail. It ceased to be a parliamentary borough in 1885. The exports are chiefly agricultural. Population (1881), 6306; (1901), 4850.

**Dunkirk,** or DUNKERQUE, a seaport and chief town of arrondissement, department of Nord, France, 53 miles north-west of Lille by rail. It has a chamber of commerce, a library, two hospitals, a college, and schools of design, painting, architecture, and music. An important wool depot and market has been established here under the auspices of the Chamber of Commerce (1900). The spinning of flax, hemp, and jute, and the manufacture of artificial manures, soap, and esparto bathing shoes, have become important industries. A shipbuilding yard covering an area of 27 acres and fitted with the newest appliances has been recently established. The first ships were laid down in 1901. Direct steamship service has been arranged with Cochin China and with South America (La Plata river). The number of vessels entered and cleared in 1900 was respectively 2698, tonnage 1,613,774, and 2622, tonnage 1,613,188; of which British vessels entered numbered 1107 of 600,672 tons, and cleared 1099 of 687,412 tons. Large quantities of produce are imported from Australia, India, and North and South America. The principal imports in 1900 were grain, coal, iron ore, nitrate of soda, wool, oil-seeds, wood, raw fibres, petroleum, pitch, metals; and the principal exports sugar, coal, iron and steel, phosphates, forage, bricks, cement. The Iceland cod-fishery, employing 83 vessels manned by 1436 men, yielded 4569 tons of fish and 280 tons of oil. The harbour accommodation has been greatly increased since 1875, and now comprises seven basins, while still further extensions are projected. The entrance canal from the sea to the outer harbour has a length of 3113 feet, width between jetties 229 feet (to be increased to 425 feet), depth ordinary spring tide 27 feet. The total length of quayage is nearly 5 miles. A canal connects the docks with the inland canals. Three lighthouses now mark the approach to the port, of which one at an altitude of 193 feet is visible 42 miles. Population (1881), 34,769; (1901), 40,329.

**Dunkirk,** a city of Chautauqua county, New York, U.S.A., in 42° 29′ N. lat. and 79° 20′ W. long., on the

south shore of Lake Erie. It is regularly laid out, has a good harbour, with a fair share of the lake commerce, and is entered by no fewer than five railways, which give it a large inland trade. It is a manufacturing city, and contains locomotive works. Population (1880), 7248; (1890), 9416; (1900), 11,616, of whom 3338 were foreign-born.

**Dunmore,** a borough of Lackawanna county, Pennsylvania, U.S.A., in the anthracite coal region, at an altitude of 939 feet. It is on the Erie and Wyoming Valley Railway. The mining and handling of anthracite coal constitute its principal, almost its sole, industry. Population (1880), 5151; (1890), 8315; (1900), 12,583, of whom 3103 were foreign-born.

**Dunmow,** a town in the Epping parliamentary division of Essex, England, 12 miles north-west by north of Chelmsford by rail. It ceased to be a corporate town in 1886, and the town hall (1578) has been purchased by a company. Area of parish, 6795 acres; population (1881), 3005; (1901), 2704.

**Dunoon,** a watering-place and police burgh (1868) of Argyllshire (including Dunoon, Kirn, and Hunter's Quay), on the west shore of the Firth of Clyde, nearly opposite Greenock. Recent constructions are a combination hospital, a new pier at Dunoon, and a court house. An esplanade has been laid out, and Dunoon Castle and grounds made into a place of recreation. A statue of Burns's "Highland Mary" was erected in 1898. One of the public schools is a grammar school. Population (1881), 4692; (1901), 6772.

**Duns,** a burgh of barony, police burgh, and railway station of Berwickshire, Scotland, 44 miles east-south-east of Edinburgh by road. There are a town hall, county buildings, a corn exchange, a mechanics' institute, and a public library. Duns has become the virtual county town of Berwickshire, and the county buildings are being enlarged with a view to its being legally constituted as such. Population (1881), 2438; (1901), 2206.

**Dunstable,** a municipal borough and market town in the Luton parliamentary division of Bedfordshire, England, 37 miles north by west of London by rail. A grammar school has been founded out of the funds of the Ashton charity, and an endowed school built. Extensive printing works have been established. Area, 453 acres; population (1881), 4627; (1901), 5147.

**Dupanloup, Félix Antoine Philibert,** French ecclesiastic (1802–1878), was born in Savoy on 3rd January 1802. In his earliest years he was confided to the care of his brother, a priest in the diocese of Chambéry. In 1810 he was sent to a *pensionnat ecclésiastique* at Paris. Thence he went to the seminary of St Nicolas de Chardonnel in 1813, and was transferred to the seminary of St Sulpice at Paris in 1820. In 1825 he was ordained priest. In the same year he became vicar of the Madeleine at Paris. He became the founder of the celebrated Academy at St Hyacinthe, and received a letter from Gregory XVI. eulogizing his work there, and calling him *Apostolus juventutis*. His imposing height, his noble features, his brilliant eloquence, as well as his renown for zeal and charity, made him a prominent feature in French life for many years. Crowds of persons attended his addresses, on whom his energy, command of language, powerful voice, and impassioned gestures made a profound impression. When made bishop of Orleans in 1848, he pronounced a fervid panegyric on Joan of Arc, which attracted attention in England as well as France. Before this he had been sent by Archbishop Affre to Rome, and had been appointed Roman Prelate and Protonotary Apostolic. For thirty years he remained a notable figure in France. He instituted the celebrated catechetical method of St Sulpice, and, with Mgr. Darboy, took a prominent part in opposing the proclamation of papal infallibility in 1870. He died on 11th October 1878. (J. J. L.*)

**Düppel,** a village of Prussia, province of Schleswig-Holstein, opposite the little town of Sonderburg (on the island of Alsen), the scene of bloody contests between the Germans and the Danes. Here in 1848 the former were repelled by the latter. The Danes then constructed strong earthworks at this spot, the key of Alsen, which, however, were stormed by the Germans in the following year. At the outbreak of the war between Denmark and Austria-Prussia in 1864 the Danes had established themselves in this same position behind a dozen lines of earthworks, but their defences were stormed by the Prussians on the 18th April of the year named. After being still further strengthened and linked with similar defences at Sonderburg, the Düppel entrenchments were abandoned in 1881 in favour of the project of fortifying Kiel.

**Dupuy, Charles Alexandre** (1851——), French statesman, was born at Le Puy, 5th November 1851, his father being a local official. After being a professor of philosophy in the provinces, he was appointed a school inspector, and thus obtained a practical acquaintance with the needs of French education. In 1885 he was elected to the Chamber as an Opportunist Republican. After acting as "reporter" of the budget for public instruction, he became minister for the department, in M. Ribot's cabinet, in 1892. In April 1893 he formed a ministry himself, taking as his office that of minister of the interior, but resigned at the end of November, and on 5th December was elected president of the Chamber. During his first week of office an anarchist, Vaillant, who had managed to gain admission to the Chamber, threw a bomb at the president, and M. Dupuy's collected bearing and conduct on this occasion gained him much credit. In May 1894 he again became premier and minister of the interior; and he was by President Carnot's side when the latter was stabbed to death at Lyons in June. He then became a candidate for the presidency, but was defeated, and his cabinet remained in office till January 1895; it was under it that Captain Dreyfus was arrested and condemned (23rd December 1894). The progress of *l'affaire* then cast its shadow upon M. Dupuy, along with other French "ministrables," but in November 1898, after M. Brisson had at last remitted the case to the judgment of the Cour de Cassation, he formed a cabinet of Republican concentration. In view of the apparent likelihood that the judges of the criminal division of the Cour de Cassation —who formed the ordinary tribunal for such an appeal— would decide in favour of Dreyfus, it was thought that M. Dupuy's new cabinet would be strong enough to reconcile public opinion to such a result; but, to the surprise of outside observers, it was no sooner discovered how the judges were likely to decide than M. Dupuy proposed a law in the Chamber transferring the decision to a full court of all the divisions of the Cour de Cassation. This arbitrary act, though adopted by the Chamber, was at once construed as a fresh attempt to maintain the judgment of the first court-martial; but in the interval President Faure (an anti-Dreyfusard) died, and the accession of M. Loubet doubtless had some effect in quieting public feeling. At all events, the whole Cour de Cassation decided that there must be a new court-martial, and M. Dupuy at once resigned (June 1899).

**Dupuy de Lôme, Stanislas Charles Henri Laurent** (1816–1885), French naval architect, the son of a retired naval officer was born at Ploemeur, near

Lorient, on 15th October 1816. He entered the École Polytechnique in 1835, and in 1842 was sent to England to study and report on iron shipbuilding. Acting on his report, which was published in 1844, the Government built their first iron vessels under his supervision. He planned and built the steam line-of-battle ship *Napoleon* (1848–52), and devised the method of altering sailing ships of the line into steamers, which was afterwards extensively practised in both France and England. He also showed the practicability of armouring the sides of a ship, and the frigate *Gloire* gave a very clear demonstration of his views. It was the beginning of the great change in the construction of ships of war which has been going on ever since. In 1857 Dupuy de Lôme was appointed "chef de la direction du matériel," at Paris; and in 1861 "inspecteur général du matériel de la marine." In 1866 he was elected a member of the Académie des Sciences. At the beginning of the war with Germany in 1870 he was appointed a member of the Committee of Defence, and during the siege of Paris occupied himself with planning a steerable balloon, for carrying out which he was given a credit of 40,000 fr.; but the balloon was not ready till a few days before the capitulation. The experiments that were afterwards made with it did not prove entirely satisfactory. In 1875 he was busy over a scheme for embarking a railway train at Calais, and exhibited plans of the improved harbour and models of the "bateaux porte-trains" to the Académie des Sciences in July. In 1877 he was elected a senator for life. He received the cross of the Legion of Honour in 1845, was made a commander in 1858, and grand officer in December 1863. He died at Paris on 1st February 1885. (J. K. L.)

**Duquesne,** a borough of Allegheny county, Penn., U.S.A., on the Monongahela river, and on a line of the Pennsylvania Railway, a few miles south-east of Pittsburg. It is an iron-manufacturing place of recent growth. Population (1900), 9036, of whom 3451 were foreign-born and 192 negroes.

**Durance** (ancient *Druentia* or *Durentia*, from Celtic "dour," water), a river of South-East France, tributary to the Rhone. It rises in the department of Hautes Alpes, near the Italian frontier, at the foot of the Gondran Pass, 3 or 4 miles in direct line east of Briançon. Here, in a valley open to the north and dominated by lofty mountains, are deep ponds apparently with no outlet, but really drained by a subterranean channel which issues 2 miles to the north. The stream then flows south-west, passing Mont Genèvre, and at the hamlet of Alberts is joined by the Clairée, a mountain torrent from the north. The Durance passes Briançon through a defile between that town and the fortress of Trois-Têtes, and about 5 miles lower bends to the south and flows for 1½ miles through the deep gorge of Bessié or Baissée. Between Savine and Sisteron, in Basses Alpes, the river forms a wide western bend, separating the departments of Hautes and Basses Alpes. At Sisteron it is joined by an important tributary, the Beuch, and a little below Volonnes is joined on the left bank by the Bleône. It borders for 2½ miles the department of Var, where it is joined by its most important tributary, the Verdon. It then flows west and north-west between the departments of Vaucluse and Bouches du Rhône, and falls into the Rhone 3 miles below Avignon. Its length is 217 miles, and the area of its basin 5800 square miles. The breadth is extremely variable—sometimes very small, sometimes spreading to nearly 1½ miles. At its outfall in the Rhone the breadth is only about 130 yards. The Durance preserves throughout its whole course the character of a torrent, and it is consequently quite useless for navigation, but for irrigation purposes it is of the highest importance. Formerly reckoned one of the three great scourges of Provence, it is now a source of immense benefit. In the departments of Vaucluse and Bouches du Rhône it irrigates nearly 100,000 acres, and tracts in the Crau formerly sterile and almost worthless are now amongst the best lands in France. Its virtue as a fertilizing agent is largely due to the immense quantity of rich mud which it brings down, containing, according to M. Hervé-Mignon, as quoted by Joanne, "as much assimilable nitrogen as 100,000 tons of excellent guano, and as much carbon as would be supplied by a forest of 121,000 acres." Amongst the principal irrigation canals which the Durance supplies are those of Peyrolles, Marseille, Crapannes, Cabédan Neuf, Alpines, Chateaurenard and Eyragues, and Rognonas. Barrage reservoirs in the defile of the Upper Durance and of the Verdon augment and regulate the supply of water to the canals. The Durance is classed as flotable from the bridge of St Clement (Hautes Alpes) to the Rhone, a length of 159 miles, but the amount of traffic is small. It is believed that in a former geologic period the Durance flowed as an independent river through the valley now traversed by the Canal des Alpines to the Gulf of Fos, though probably having a subsidiary connexion with the Rhone by one or more arms.

**Durango,** a state of Mexico, bounded on the N. by that of Chihuahua, on the E. and S.E. by the state of Coahuila; Zacatecas and the Territory of Tepic on the S., and Sinaloa on the W. It has an area of 38,020 square miles. The population in 1879 was 190,846, and in 1900 was 371,274. It is one of the richest states of the Republic as to agriculture, mining, and stock-raising, and is divided into 13 *partidos* and 49 municipalities. The capital, Durango, 574 miles from the city of Mexico, has a population of 26,425, and contains many fine buildings, notably the cathedral, one of the handsomest in the Republic, besides a mint, city and suburban railways, electric lights, cotton and woollen mills, foundries, flour and sugar mills. Amongst other cities are Villa Lerdo, Guanacevi (6859), San Juan de Guadalupe, Nombre de Dios, San Dimas, and El Oro.

**Durazzo,** a Turkish seaport on the Adriatic, and the chief town of the sanjak of Durazzo, in Albania. The chief exports are olive oil—largely manufactured in the district—wheat, oats, barley, pottery, and skins. The population is about 5000.

**Durban,** seaport town of Natal, South Africa. It has a population within the township of 39,245 (1898), namely, 17,705 Europeans, 10,924 natives, and 10,616 Indians. It is well laid out, has many good public buildings, including a very fine town hall, central railway station, and public baths. It has an extensive system of electric lighting and an efficient drainage scheme. A tram service connects the Point, the town proper, and the Berea, which is the residential suburb. The rateable value of the borough in 1899 was £5,626,695. The harbour, which used to be impeded by a bar, has been much improved of late years, and this change, besides leading to a large increase of shipping business, was of material service in connexion with the Boer war.

**Düren,** a town of Prussia, in the Rhine province, on the river Roer, 19 miles by rail east from Aix-la-Chapelle. It is the seat of cloth, paper, carpet, flax-spinning, artificial wool, sugar, iron-wares, and other manufactures. Here are several new buildings and monuments—the former embracing the provincial lunatic asylum and the church of St Joachim; the latter, monuments to the Emperors William I. and II., Bismarck, and the war of 1870–71.

The town hall contains a collection of antiquities. There are also a synagogue, technical school, library, and hospital. Population (1885), 19,802; (1901), 27,171.

**Durham,** a north-eastern county of England, bounded S.E. and S. by Yorkshire, W. by Westmoreland and Cumberland, N.W. and N. by Northumberland, and E. by the North Sea.

*Area and Population.*—The area of the ancient and administrative county, as given in the census tables of 1891, was 647,281 acres or 1011 square miles, with a population in 1881 of 867,576 and in 1891 of 1,016,559, of whom 517,942 were males and 498,617 females, the number of persons per square mile being 1005, and of acres to a person 0·64. In 1895 the area of the administrative county was slightly enlarged, by the transference from the North Riding of Yorkshire of the area which, prior to the passing of the Local Government Act, 1894, constituted the part of the township of Linthorpe in the borough of Stockton. The area of the registration county is 764,788 acres, with a population in 1891 of 1,024,369, of whom 668,782 were urban and 355,587 rural. Within the registration area the population between 1881 and 1891 increased 26·28 per cent. The excess of births over deaths between 1881 and 1891 was 169,257, and the actual increase of the resident population was 148,885. In 1901 the population was 1,187,324.

The following table gives the number of marriages, births, and deaths, with the number of illegitimate births, for 1880, 1890, and 1898:—

| Year. | Marriages. | Births. | Deaths. | Illegitimate Births. | |
|---|---|---|---|---|---|
| | | | | Males. | Females. |
| 1880 | 6419 | 33,197 | 19,796 | 704 | 681 |
| 1890 | 8534 | 36,955 | 20,767 | 668 | 663 |
| 1898 | 9977 | 40,240 | 22,169 | 718 | 723 |

The number of marriages in 1899 was 10,101; of births, 40,991; and of deaths, 22,530.

The following table shows the marriage-, birth-, and death-rates per 1000 of the population, with the percentage of illegitimate births, for a series of years:—

| | 1870-79. | 1880. | 1889. | 1888-97. | 1898. |
|---|---|---|---|---|---|
| Marriage-rate | 17·3 | 14·9 | 16·9 | 15·7 | 17·5 |
| Birth-rate | 44·3 | 38·5 | 36·5 | 36·0 | 35·2 |
| Death-rate | 24·0 | 22·9 | 20·5 | 19·3 | 19·4 |
| Percentage of illegitimate births | 4·2 | 4·2 | 3·6 | 3·8 | 3·6 |

The birth-rate is much above the average, and the death-rate is also above it, but the percentage of illegitimate births is considerably below it.

In 1891 the number of Scots in the county was 26,857, of Irish 27,663, and of foreigners 5366.

*Constitution and Government.*—The county is divided into eight parliamentary divisions, and it also includes the parliamentary borough of Sunderland, returning two members; and the boroughs of Darlington, Durham, Gateshead, Hartlepool, South Shields, and Stockton-on-Tees, each returning one member. There are nine municipal boroughs: Darlington (44,496 in 1901), Durham (14,641), Gateshead (109,887), Hartlepool (22,737), Jarrow (34,294), South Shields (97,267), Stockton-on-Tees (51,476), Sunderland (146,565), and West Hartlepool (62,614); Gateshead, South Shields, and Sunderland are county boroughs. The following are urban districts: Hebburn (20,901), Hetton (13,673), Houghton-le-Spring (7858), Leadgate (4658), Ryton (8448), Seaham Harbour (10,163), Shildon and East Thickley (11,759), Southwick (12,643), Spennymoor (16,661), Stanhope (1964), Stanley (13,553), Tanfield (8178), Tow Law (4371), Whickham (12,851), and Willington (7887).

Durham is in the north-eastern circuit, and assizes are held at Durham. The boroughs of Darlington, Durham, Gateshead, Hartlepool, Jarrow, South Shields, Stockton-on-Tees, and Sunderland have separate commissions of the peace. The ancient county, which is in the diocese of Durham, contains 238 ecclesiastical parishes, and parts of two others.

*Education.*—The city of Durham (*q.v.*) is the seat of a university, and it has also a residential training college (diocesan) for schoolmasters and schoolmistresses. At Ushaw, near Durham, there is a Roman Catholic college. The number of elementary schools on 31st August 1899 was 519, of which 187 were board and 332 voluntary; the latter including 218 National Church of England schools, 19 Wesleyan, 54 Roman Catholic, and 51 "British and other." At South Shields there is a board school for blind children; there is another at Sunderland; Darlington and Stockton-on-Tees have each a board school for deaf children. The average attendance at board schools in 1899 was 93,095, and at voluntary schools 91,713. The total school board receipts for the year ended 29th September 1899 were over £356,360. The income under the Technical Instruction Act was over £1289; that under the Agricultural Rates Act was over £2343.

*Agriculture.*—Nearly two-thirds of the total area of the county are under cultivation, but nearly two-thirds of this are in permanent pasture. There are also about 49,000 acres of hill-pasture, and 29,000 acres under woods. Of the area under corn crops, which has greatly diminished, oats occupy about one-half, and wheat and barley each about a fourth. Nearly two-thirds of the acreage under green crops are occupied by turnips, many cattle being raised. The following table gives the acreages of the larger main divisions of the cultivated area at intervals of five years from 1880:—

| Year. | Total Area under Cultivation. | Corn Crops. | Green Crops. | Clover. | Permanent Pasture. | Fallow. |
|---|---|---|---|---|---|---|
| 1880 | 415,626 | 90,771 | 34,835 | 44,582 | 226,867 | 19,155 |
| 1885 | 423,421 | 81,645 | 35,267 | 48,265 | 241.900 | 16,332 |
| 1890 | 435,084 | 73,065 | 32,285 | 56,518 | 260,064 | 12,886 |
| 1895 | 439,144 | 65,038 | 33,023 | 53,907 | 277,355 | 9,425 |
| 1900 | 438,713 | 65,726 | 33,488 | 51,780 | 280,190 | 7,186 |

The following table gives particulars regarding the live stock for the same years:—

| Year. | Horses. | Total Cattle. | Cows or Heifers in Milk or in Calf. | Sheep. | Pigs. |
|---|---|---|---|---|---|
| 1880 | 16,839 | 62,395 | 21,124 | 214,427 | 7,732 |
| 1885 | 16,586 | 69,427 | 25,202 | 198,471 | 11,913 |
| 1890 | 17,925 | 69,037 | 26,004 | 224,504 | 14,758 |
| 1895 | 20,425 | 71,968 | 26,190 | 225,041 | 12,894 |
| 1900 | 20,167 | 78,183 | 28,822 | 258,257 | 10,024 |

*Industries and Trade.*—According to the annual report for 1898 of the chief inspector of factories (1900), the total number of persons employed in factories and workshops in 1897 was 99,219, as compared with 95,115 in 1896. Only 1760 were employed in textile factories. As many as 90,039 were employed in non-textile factories, there being an increase between 1895 and 1896 of 7·3 per cent., and between 1896 and 1897 of 4·1 per cent. More than half (46,376) were employed in the manufacture of machines, appliances, conveyances, tools, &c. This includes those employed in the iron and steel shipbuilding yards of the Tyne, Stockton-on-Tees, and the Hartlepools. The Tyne shipbuilding industry is second only to that of the Clyde, and the greater portion of it is carried on within the Durham boundaries. The total number of ships built in the Tyne ports and at the Hartlepools, Stockton, and Sunderland in 1895 was 174, with a tonnage of 229,868; in 1898 it was 224, with a tonnage of 319,705. Next to shipbuilding the most important industry is the founding and conversion of metal, which in 1897 employed 17,980 persons, the extraction of metal employing 3148. Other industries are the manufacture of paper, &c., employing 3211 persons; of chemicals (chiefly on the Tyne), employing 3289; and of glass (at Gateshead and Sunderland), employing 3264; and of clay, stone, &c. (chiefly earthenware at Gateshead and Sunderland), 3195. In workshops, 7240 persons were employed—4403 in clothing industries. The total number of persons employed in mines and quarries in 1899 was 111,720. Of limestone 1,944,207 tons were raised in 1899, the largest amount of any county in the United Kingdom, of clays 744,453 tons, of which 498,011 were mainly fireclay, of sandstone 82,048 tons, of igneous rocks 73,644 tons, and of gravel and sand 20,471 tons. But the most important mineral is coal. The coalfield of Durham is at present by far the most productive of England; and although the county's output of iron is inconsiderable, its proximity to the great Cleveland iron region of North Yorkshire enables it now to produce over 1,000,000 tons of pig iron annually. There is also a very large production of salt from brine. The following table gives particulars regarding the more valuable minerals in 1890 and 1899:—

| Year. | Coal. | | Ironstone. | | Lead. | | Salt. | |
|---|---|---|---|---|---|---|---|---|
| | Tons. | Value. | Tons. | Value. | Tons. | Value. | Tons. | Value. |
| 1890 | 30,265,241 | £11,034,202 | 11,488 | £3591 | 9781 | £81,422 | 119,971 | £64,990 |
| 1899 | 34,870,675 | 12,065,153 | 16,960 | 6360 | 3361 | 32,958 | 197,610 | 93,868 |

The only fishing stations mentioned in the annual return relating to the sea fisheries of the United Kingdom are Sunderland and East Hartlepool, the total quantity of fish landed in 1898 being 118,884 cwt., valued at £95,826.

**Durham,** a city, municipal and parliamentary borough (since 1885 returning only one member), and county town of Durham, England, on the Wear, 256 miles from London by rail. The cathedral has undergone extensive repairs and the chapter-house been restored. The grammar school, the diocesan training colleges for schoolmasters and schoolmistresses, and the County Hospital have been enlarged. A mission church, a high school for girls, and the Shire Hall and County Buildings have been erected. Manufactures of hosiery and iron-works have been introduced. Area of municipal borough, 880 acres; population (1881), 14,932; (1901), 14,641. (See UNIVERSITIES.)

**Durham,** capital of Durham county, North Carolina, U.S.A., on the Southern, the Norfolk and Western, and the Sea Board Air Line Railways, at an altitude of 392 feet. It is the seat of Trinity College, a Methodist Episcopal institution. The surrender of General J. E. Johnston, at the close of the Civil War, took place in this neighbourhood on 25th April 1865. The growth and prosperity which have come to the city since the Civil War are due to the development of its tobacco manufactures. Population (1880), 2041; (1890), 5485; (1900), 6679, of whom 108 were foreign-born and 2241 negroes.

**Durlach,** a town of Germany, grand-duchy of Baden, $2\frac{1}{2}$ miles by rail east from Carlsruhe. A funicular railway runs to the top of the Turmberg. Gardening, iron-founding, and the manufacture of sewing and other machines, starch, chicory, and pottery are carried on. Population (1885), 7656; (1901), 11,353.

**Duruy, Jean Victor** (1811–1894), French historian and statesman, was born in Paris on 11th September 1811. The son of an artisan, he was at first intended for his father's trade, but succeeded in passing brilliantly through the École Normale Supérieure, and then held a succession of professorships and educational inspectorships. He assisted Napoleon III. in his life of Julius Cæsar, and his abilities being thus brought under the emperor's notice, he was in 1863 appointed Minister of Education. In this position he displayed incessant activity, and a desire for broad and liberal reform which aroused the bitter hostility of the clerical party. Among his measures may be cited his organization of higher education ("enseignement spécial"), his foundation of the "conférences publiques," which have now become universal throughout France, and of a course of secondary education for girls by lay teachers, and his introduction of modern history and modern languages into the curriculum both of the *lycées* and of the colleges. He greatly improved the state of primary education in France, and proposed to make it compulsory and gratuitous, but was not supported in this project by the emperor. In the new cabinet that followed the elections of 1869, Duruy was replaced by Bourbeau, and was made a senator. After the fall of the Empire he took no part in politics, except for an unsuccessful candidature for the Senate in 1876. From 1881 to 1886 he served as a member of the Conseil Supérieur de l'Instruction Publique. In 1884 he was elected to the Académie Française in succession to Mignet. He died in Paris on 25th November 1894. Duruy's fame as a historian rests mainly on the revised edition of his Roman history. First published in 2 vols. under the title of *Histoire des Romains et des peuples soumis à leur domination* (1843–44), it appeared in a greatly enlarged form in 7 vols. under the title of *Histoire des Romains depuis les temps les plus reculés jusqu'à la mort de Théodose* (1876–85); a magnificent illustrated edition was published from 1879 to 1885 (English translation by W. J. Clarke, in 6 vols., 1883–86). His *Histoire des Grecs*, similarly illustrated, appeared in 3 vols. from 1887 to 1889 (English translation in 4 vols., 1892). He was the editor, from its commencement in 1846, of the *Histoire universelle, publiée par une société de professeurs et de savants*, for which he himself wrote a "Histoire sainte d'après la Bible," "Histoire grecque," "Histoire romaine," "Histoire du moyen âge," "Histoire des temps modernes," and "Abrégé de l'histoire de France." His other works include *Atlas historique de la France accompagné d'un volume de texte* (1849); *Histoire de France de 1453 à 1815* (1856), of which an expanded and illustrated edition appeared as *Histoire de France depuis l'invasion des barbares dans la Gaule romaine jusqu'à nos jours* (1892); *Histoire populaire de la France* (1862–63); *Histoire populaire contemporaine de la France* (1864–66); *Causeries de voyage* (1864); and *Introduction générale à l'histoire de France* (1865). A memoir by Ernest Lavisse appeared in 1895 under the title of *Un Ministre: Victor Duruy.* (H. SY.)

**Düsseldorf,** a town of Prussia, in the Rhine province, on the right bank of the Rhine, 24 miles by rail north by west from Cologne. Düsseldorf is one of the handsomest cities of Western Germany. Its situation on the great mid-European waterway and as the junction of several main lines of railway has largely favoured its rapid growth and industrial development. It is the principal banking centre of the Westphalian coal and iron trade, and the favourite residence of the leading merchants of the lower Rhine. Of late the city has been much extended and improved. New quays, with a magnificent harbour, affording accommodation for vessels of deep draught, have been built, and the trade with the Dutch ports and with London thereby greatly enhanced. On the south side the town has been of late completely metamorphosed by the removal of Köln-Mindner and Bergisch Maerkisch stations to a new central station lying to the east. The site gained has been converted into new boulevards, while the railway to Neuss and Aix-la-Chapelle has been diverted through the suburb of Bilk and thence across the Rhine by a new iron bridge. A new road bridge (completed 1898, 2087 feet long), replacing the old bridge of boats, carries the electric tram-line to Crefeld. Düsseldorf ranks as one of the art centres of Europe, and is especially famous for its school of painting, which is largely attended. Many handsome modern buildings have been recently erected. The west wing of the town hall was rebuilt in 1885. The building of the academy of art, in the Renaissance style, was erected in 1879–81. The art exhibition (1881), with a mosaic façade, contains the municipal picture gallery and a permanent exhibition of pictures. In front of it stands a bronze statue of Bismarck (1899). In the old town there are, further, the industrial art museum (1896), the historical museum, and the industrial art school (1882). In the quarters which lie east and north of the old town the most noteworthy of the newer buildings are the Johannes (1875–81), St Rochus, and the Heil Empfàngniss Kirchen (1896); the law courts; the Roman Catholic hospital of St Mary; the state archives; the bronze statue of Cornelius, by Donndorf (1879); the bronze equestrian statue of the Emperor William I. (1896); and the war memorial in the botanical gardens. To the south of the old town lie the assembly hall of the Rhenish provincial diet, an Italian

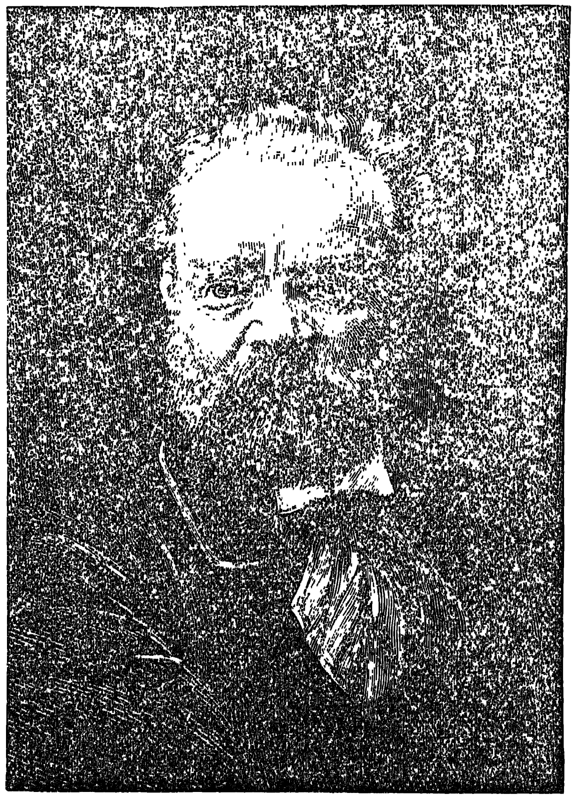
Renaissance edifice (1879), and in front of it a large bronze group representing the river Rhine and its chief tributaries, by Tüshaus and C. Janssen (1897); Petri Kirche; and the house in which the poet Freiligrath (1810–76) lived. Farther south, in the suburb of Bilk, there are the Flora Garten and the Volks Garten, the astronomical observatory (51° 12′ 25″ N. lat., 6° 46′ 13″ E. long.), and the harbour. Towards the extreme north-east lie the zoological gardens. Within quite recent years Dusseldorf has made remarkable progress as an industrial centre. The first place is occupied by the iron industries, embracing foundries, furnaces, engineering and machine shops, &c. Next come cotton spinning and weaving, calico printing, yarn-spinning, dyeing, and similar textile branches, besides a variety of other industries. Population (1885), 115,190; (1890), 144,642; (1895), 175,985; (1900), 212,949.

**Dutch East Indies.** See MALAY ARCHIPELAGO.

**Dux** (Czech, *Duchovcov*), a town in the government district of the same name in Bohemia, Austria; the centre of an extensive lignite or brown coal deposit, which is worked in sixteen different pits. It has also a steam corn-mill and a sugar refinery, and manufactures glass, porcelain, earthenware, and hosiery. There are numerous memorials of Wallenstein in the château of Count Waldstein, which also contains a collection of arms and armour, a picture gallery, and a library of about 24,000 volumes. Population in 1890, 10,141; in 1900, 11,921, the majority German and Catholic (Czechs, estimated at 29 per cent.; Protestants and Jews, 1 per cent. each).

**Dvinsk,** the official name (since 1893) of DÜNABURG, a fortress of Western Russia, and district town of the government, 183 miles by rail north-west of Vitebsk, on the right bank of the Düna, and at the crossing of two main lines—Riga-Smolensk and Wilno-St Petersburg. It is the chief strategic position for the defence of the Düna. The population of Dvinsk rapidly increased from 25,764 in 1860, to 72,230 in 1897. It consists chiefly of Jews (about 30,000), Lithuanians, and Letts.

**Dvořák, Anton** (1841–——), Bohemian musical composer, born at Nelahozeves (otherwise Mühlhausen) in Bohemia on 8th September 1841, was the son of Frantisek Dvořák, a small publican and village butcher. At the door of his father's inn Dvořák first imbibed the "concord of sweet sounds" uttered by peripatetic musicians, and there he first appeared as a practical musician, taking his place among the fiddlers who scraped out their "furiants" and other wild dances for the benefit of the holiday-making local beaux and belles. At the village school he learnt from Josef Spitz both to sing and to play the violin with so much effect that soon he was able to assist in the parish church services. But the seriousness of life came home soon to the youth, who at twelve years old was sent by his father to Zlonic, near Schlan, to an uncle, with whom he lived while passing through the higher-grade classes at school. Here, too, he was fortunate enough to find a valuable friend in A. Liehmann, organist and chief musician of the little town, a competent musician, who instructed the boy in elementary theory, organ and pianoforte playing. The theory studies, however, could not long be continued, since Liehmann soon acknowledged in his own dialect that "Aus Tonda, dem Sapperments-buben 'mal 'was werden könnte," at the same time realizing that he could not do much to assist. But Dvořák soon left Zlonic for Böhmisch-Kamnitz, where he learnt German and advanced his musical studies under Hancke. A year later he was summoned to return to Zlonic to assist his father, who had set up in business there. But his craving for a musical career was not to be denied, and after considerable trouble with Dvořák senior, consent was obtained to his settling in Prague in order to devote himself entirely to music. In October 1857 Dvořák entered the organ-school of the "Gesellschaft der Kirchenmusik," where he worked for three years. The small financial aid his father was at first able to lend soon ceased, and after being in Prague but a few months Dvořák found himself practically thrown on his own resources to obtain a livelihood. This he obtained precariously by playing the viola in a private orchestra and by making music in various inns of the town. On the opening in 1862 of the Bohemian Interimstheater, Dvořák, with part of this band, formed the nucleus of the theatrical orchestra, and remained connected with it for eleven years, when he became organist of the church of St Adalbert. At this time his small stipend was augmented slightly by the fees of a few pupils, though the privations



ANTON DVOŘÁK.
*(From a photograph by Draycott, London.)*

suffered by him and his wife—whom he had recently married—must have been great. But in spite of financial worry and of the amount of time he had to devote to his professional duties and private pupils, Dvořák found leisure not only for his own studies of the classics, but also to compose. His work, like his daily life, was beset with difficulties, for he had not the means to provide himself with sufficient music-paper, much less to hire a pianoforte; and it is possible that several of his important early works would never have been written had it not been for the generosity of Karel Bendl, the distinguished composer, who helped him in many ways.

Dvořák himself has said since that he retained no recollection of much that he then composed. In and about 1864 two symphonies, a host of songs, some chamber-music, and an entire opera, *Alfred*, lay unheard in his desk. The libretto of this opera was made up from

materials found in an old almanack. Most of these works were burnt long ago. In 1873 he made his first bid for popularity by his patriotic hymn *Die Erben des weissen Berges* (published many years later as Op. 30). Its reception was enthusiastic, and Dvořák's subsequent works were eagerly awaited and warmly received on production. In 1874 his opera *König und Köhler* resulted in a fiasco at Prague, owing to its mixture of styles. Nothing daunted, Dvořák recomposed the whole work in three months. In 1875 he obtained a stipend from the Kultus-Ministerium at Vienna on the recommendation of Brahms and Hanslick, which freed him from care and enabled him to indulge in composition to his heart's content. Following on this success came a commission in 1877 from Simrock in Berlin for a series of Slavic dances, which took the public by storm. Immediately compositions, old and new, began to pour from the publisher. English sympathy was entirely won by the *Stabat Mater* in 1883, and increased by the symphonies in D, D mi., and F, G, and E mi. (*The American*), and the cantata *The Spectre's Bride*, but somewhat chilled by the oratorio *St Ludmila*, a comparatively feeble work written "to suit English taste" for the Leeds Festival of 1886. The three overtures Opp. 91, 92, 93, failed to hold their place, but the pseudo-American symphony has become one of Dvořák's most popular works, and much of his chamber-music, of which there is abundance, seems quite permanent in its place in concert programmes. In 1892, after having frequently visited England, Dvořák took up the duties of head of the principal American school of music in New York. There he remained till 1895, when he returned to Prague.

Dvořák's music is characteristically national, though less purely so than that of Smetana. His industry is monumental; but in spite of his dramatic talent, none of his operas has been really successful. A past master of the orchestra and a composer of real individuality, he has earned and deserved his place among the elect, not only by his great gifts, but by his abnormal energy in their development.

**Dyeing.**—Dyeing is the art of colouring textile and other materials in such a manner that the colours will not be readily removed by those influences to which they are likely to be submitted—*e.g.*, washing, rubbing, light, &c.

***Historical sketch.***

The materials usually dyed are those made from the textile fibres, silk, wool, cotton, &c., and intended for clothing or decoration; but in addition to these may be mentioned straw, fur, leather, paper, &c. The art of dyeing dates from prehistoric times, and its practice probably began with the first dawn of civilization. Although we cannot trace the successive stages of its development from the beginning, we may suppose they were somewhat similar to those witnessed among certain uncivilized tribes to-day—*e.g.*, the Maoris of New Zealand. At first the dyes were probably mere fugitive stains obtained by means of the juices of fruits, and the decoctions of flowers, leaves, barks, and roots; but in course of time methods were discovered, with the aid of certain kinds of earth and mud containing alumina or iron, whereby the stains could be rendered permanent, and then it was that the true art of dyeing began. There is no doubt that dyeing was, in the early period of its history, a home industry practised by the women of the household, along with the sister arts of spinning and weaving, for the purpose of embellishing the materials manufactured for clothing.

Historical evidence shows that already at a remote period a high state of civilization existed in Persia, India, and China, and the belief is well founded that the arts of dyeing and printing have been practised in these countries during a long succession of ages. In early times the products and manufactures of India were highly prized throughout Southern Asia, and in due course they were introduced by Arabian merchants to Phœnicia and Egypt, with which countries commercial intercourse, by way of the Persian and Arabian Gulfs, seems to have existed from time immemorial. Eventually the Egyptians themselves began to practise the arts of dyeing and printing, utilizing no doubt both the knowledge and the materials derived from India. Pliny the historian has left us a brief record of the methods employed in Egypt during the first century, as well as of the Tyrian purple dye celebrated already 1000 B.C., while the chemical examination of mummy cloths by Thomson and Schunck testifies to the use by the Egyptian dyers of indigo and madder. The Phœnician and Alexandrian merchants imported drugs and dyestuffs into Greece, but we know little or nothing of the methods of dyeing pursued by the Greeks and Romans, and such knowledge as they possessed seems to have been almost entirely lost during the stormy period of barbarism reigning in Europe during the 5th and succeeding centuries. In Italy, however, some remnants of the art fortunately survived these troublous times, and the importation of Oriental products by the Venetian merchants about the beginning of the 13th century helped to revive the industry. From this time rapid progress was made, and the dyers formed important guilds in Florence, Venice, and other cities. It was about this time, too, that a Florentine named Rucellai rediscovered the method of making the purple dye orchil from certain lichens of Asia Minor. In 1429 there was published at Venice, under the title of *Mariegola dell' Arte de Tentori*, the first European book on dyeing, which contained a collection of the various processes in use at the time. From Italy a knowledge of dyeing gradually extended to Germany, France, and Flanders, and it was from the latter country that the English king Edward III. procured dyers for England, a Dyers' Company being incorporated in 1472 in the City of London. A new impetus was given to the industry of dyeing by the discovery of America in 1492, as well as by the opening up of the way to the East Indies round the Cape of Good Hope in 1498 by Vasco de Gama. A number of new dyestuffs were now introduced, and the dyewood trade was transferred from Italy to Spain and Portugal, for the East Indian products now came direct to Europe round the Cape instead of by the old trade routes through Persia and Asia Minor. Eastern art-fabrics were introduced in increasing quantity, and with them came also information as to the methods of their production. In Europe itself the cultivation of dye-plants gradually received more and more attention, and both woad and madder began to be cultivated, about 1507, in France, Germany, and Holland. Under the influence of Spain the Dutch largely developed their industries and made considerable progress in dyeing. The Spaniards, on their first arrival in Mexico (1518), noticed the employment of the red dyestuff cochineal by the natives, and at once imported it to Europe, where an increasing demand for the new colouring matter gradually developed in the course of the century. A further impetus was given to the trade by the Dutch chemist Drebbel's accidental discovery, in 1630, of the method of dyeing a brilliant scarlet on wool by means of cochineal and tin solutions. The secret was soon communicated to other dyers, and the new scarlet was dyed as a speciality at the Gobelin dye-works in Paris, and some time later (1643) at a dyeworks in Bow, near London. In 1662 the Royal Society of London gave some attention to the art of dyeing, and in order to inform and assist practical dyers, caused the

publication of the first original account, in the English language, of the methods employed in dyeing, entitled "An apparatus to the history of the common practices of Dyeing." Ten years later the French Minister Colbert sought to improve as well as control the operations of dyeing, by publishing a code of instructions for the use of the woollen dyers and manufacturers in France. From this time, too, a succession of eminent chemists were appointed by the French Government to devote some of their attention to the study of the industrial arts, including dyeing, with a view to their progress and improvement. Dufay, Hellot, Macquer, Berthollet, Roard, and Chevreul (1700–1825) all rendered excellent service to the art, by investigating the chemical principles of dyeing, by publishing accounts of the various processes in vogue, by examining the nature and properties of the dyestuffs employed, and by explaining the cause of the several phenomena connected with dyeing. With the advent of the 18th century, certain old prejudices against the use of foreign dyewoods gradually disappeared, and very rapid progress was made owing to the birth of the modern chemistry and the discovery of several useful chemical products and processes—*e.g.*, Prussian Blue (1710), Saxony Blue or Indigo Extract (1740), sulphuric acid (1774), Murexide (1776), picric acid (1788), carbonate of soda (1793), bleaching powder (1798). Experiments on the practical side of bleaching and dyeing were made during this period, in England by Thomas Henry, Home, and Bancroft, and in France by Dambourney, Gonfreville, and others, each of whom has left interesting records of his work.

Down to the middle of the 19th century natural dyestuffs alone, with but few exceptions, were at the command of the dyer. But already in the year 1834 the German chemist Runge noticed that one of the products obtained by distilling coal-tar, namely, aniline, gave a bright blue coloration under the influence of bleaching powder. No useful colouring matter, however, was obtained from this product, and it was reserved for the English chemist Perkin to prepare the first aniline dyestuff, namely, the purple colouring matter Mauve (1856). The discovery of other brilliant aniline dyestuffs followed in rapid succession, and the dyer was in the course of a few years furnished with Magenta, Aniline Blue, Hofmann's Violet, Iodine Green, Bismarck Brown, Aniline Black, &c. Investigation has shown that the products of the distillation of coal-tar are very numerous, and some of them are found to be specially suitable for the preparation of colouring matters. Such, for example, are benzene, naphthalene, and anthracene, from each of which distinct series of colouring matters are derived. In 1869 the German chemists Graebe and Liebermann succeeded in preparing Alizarin, the colouring matter of the madder-root, from the coal-tar product anthracene, a discovery which is of the greatest historical interest, since it is the first instance of the artificial production of a vegetable dyestuff. Another notable discovery is that of artificial Indigo by Baeyer in 1878. Since 1856, indeed, an ever-increasing number of chemists has been busily engaged in pursuing scientific investigations with the view of preparing new colouring matters from coal-tar products, and of these a few typical colours, with the dates of their discovery, may be mentioned: Cachou de Laval, (1873); Eosin (1874); Alizarin Blue (1877); Xylidine Scarlet (1878); Biebrich Scarlet (1879); Congo Red (1884); Primuline Red (1887); Rhodamine (1887); Paranitraniline Red (1889); Alizarin Bordeaux (1890); Alizarin Green (1895). At the present time (1901) it may truly be said that the dyer is furnished with quite an embarrassing number of coal-tar dyestuffs which are capable of producing every variety of colour possessing the most diverse properties. Many of the dyes produced are fugitive, but a considerable number are permanent and withstand various influences, so that the general result for some years has been the gradual displacement of the older dyewoods by the newer coal-tar colours.

*Mechanical improvements.*

During this period of discovery on the part of the chemist, the mechanician has been actively engaged in devising machines suitable for carrying out, with a minimum of manual labour, all the various operations connected with dyeing—*e.g.*, washing, squeezing, dyeing, drying, &c. At the present time the several textile fabrics may be dyed in each stage of their manufacture, *e.g.*, as loose unspun fibres, slubbing, tops, yarn, cops, and cloth, each requiring special forms of machine. Loose wool, which was formerly stirred about in the dye solution, is now enclosed in perforated cylinders, &c., and remains stationary, while the dye-liquor is circulated through the material by means of a pump. Wool tops and cotton cops are dyed in a similar manner. Yarn is still suspended on wooden rods and turned in the dye-liquor by hand, or the rods of yarn are suspended on revolving reels. Cloth is dyed by circulating it as an endless band over a reel placed above the dye-vessel and through the dye solution. This introduction of machinery into the dyeing trade has resulted in the production of better work, it has effected considerable economy, and may be regarded as an important feature in modern dyeing.

*General principles.*

The art of dyeing is a branch of applied chemistry in which the dyer is continually making use of chemical and physical principles in order to bring about a permanent union between the material to be dyed and the colouring matter applied. If cotton or wool is boiled in water containing finely powdered charcoal, or other insoluble coloured powder, the material is not dyed, but merely soiled or stained. This staining is entirely due to the entanglement of the coloured powder by the rough surface of the fibre, and a vigorous washing and rubbing suffices to remove all but mere traces of the colour. True dyeing can only result when the colouring matter is presented to the fibre in a soluble condition, and is then, by some means or other, rendered insoluble while it is absorbed by, or is in direct contact with, the fibre. There must always be some marked physical or chemical affinity existing between fibre and colouring matter, and this depends upon the physical and chemical properties of both. It is well known that the typical fibres, wool, silk, and cotton, behave very differently towards the solution of any given colouring matter, and that the method of dyeing employed varies with each fibre. As a general rule wool has the greatest attraction for colouring matters, and dyes most readily, cotton has the least attraction, while silk occupies in this respect an intermediate position. These differences are no doubt partly due to differences of physical structure in the fibres, but they are also in great measure owing to their different chemical composition.

On the other hand, a given fibre, *e.g.*, cotton, behaves quite differently in dyeing towards various colouring matters. Some of these are not at all attracted by it, and are incapable of being used as dyestuffs for cotton. For others cotton exhibits a marked attraction, so that it is readily dyed by mere steeping in a hot solution of the colouring matter. Again, for other colouring matters cotton has little or no attraction, and cannot be dyed with them until it has been previously impregnated or prepared with a metallic salt, tannic acid, or some other agent which is capable of combining with the colouring matter and precipitating it as an insoluble coloured compound within or upon the fibre. Such differences of behaviour are to be ascribed to differences in the chemical constitution or atomic arrangement of the various colouring matters.

In the case of the coal-tar colours we are, for the most part, well acquainted with their chemical constitution, and in accordance with this knowledge the chemist has arranged them in the following groups:—1. Nitro Colours. 2. Azo Colours, including Amido-azo, Oxy-azo, Tetrazo, and Polyazo Colours. 3. Hydrazone Colours. 4. Oxy-quinone Colours, including Quinone-oxime Colours. 5. Diphenyl methane and Triphenylmethane Colours, including Rosaniline, Rosolic acid, and Phthaleïne Colours. 6. Quinoneimide Colours, including Indamine, Indophenol, Thiazime, Thiazone, Oxazime, Oxazone, Azine, Induline, Quinoxaline, and Fluorindine Colours. 7. Aniline Black. 8. Quinoline and Acridine Colours. 9. Thiazol Colours. 10. Oxy-ketone, Xanthone, Flavone, and Cumarine Colours. 11. Indigo. 12. Colours of unknown constitution.

*Classification of colouring matters.*

This arrangement of the colouring matters in natural chemical groups is well suited for the requirements of the chemist, but another classification is that based on the mode of their application in dyeing. This is much simpler than the previous one, and being better adapted for the practical purposes of the dyer, as well as for explaining the various methods of dyeing, it is preferred for this article. According to this arrangement colouring matters are classified under the following groups:—1. *Acid Colours*. 2. *Basic Colours*. 3. *Direct Colours*. 4. *Developed Colours*. 5. *Mordant Colours*. 6. *Miscellaneous Colours*. 7. *Mineral Colours*. It is well to state that there is no sharp line of division between some of these groups, for many colours are applicable by more than one method, and might quite well be placed in two, or even three, of the above groups. This may be due either to the kind of fibre to which the colouring matter is to be applied, or to certain details in the chemical constitution of the latter which give it a twofold character.

**Acid Colours.**—These dyestuffs are so called because they dye the animal fibres wool and silk in an acid bath; they do not dye cotton. From a chemical point of view the colouring matters themselves are of an acid character, this being due to the presence in the molecule of nitro ($NO_2$) or sulphonic acid ($HSO_3$) groups. According to their origin and constitution they may be distinguished as nitro compounds, sulphonated azo compounds, and sulphonated basic colours. The Acid Colours are usually sold in the form of their alkali salts, as variously coloured powders soluble in water. For the alkali salts in neutral or alkaline solution wool and silk have little or no affinity, but dyeing rapidly occurs if the solution is acidified with sulphuric acid whereby the colour-acid is liberated. This addition of acid, however, is necessary not only to set free the colour-acid of the dyestuff, but also to alter partially the chemical composition of the fibre, and thus render it capable of uniting more readily with the free colour-acid. It has been shown, namely, that if wool is boiled with dilute sulphuric acid, and then thoroughly washed with boiling water till free from acid, it acquires the property of being dyed with Acid Colours even in neutral solution. By this treatment a portion of the wool substance is converted into so-called *lanuginic acid*, which has a strong attraction for the colour-acid of the dyestuff, with which it forms an insoluble coloured compound. For dyeing *wool*, the general rule is to charge the dyebath with the amount of dyestuff necessary to give the required colour, say from ½ to 2 or 6 per cent. on the weight of wool employed, along with 10 per cent. sodium sulphate (Glauber's salt) and 4 per cent. sulphuric acid (1·84° sp. gr.). The woollen material is then introduced and continually handled or moved about in the solution, while the temperature of the latter is gradually raised to the boiling-point in the course of ¾ to 1 hour; after boiling for ¼ to ½ hour longer, the operation is complete, and the material is washed and dried.

In practice, modifications of this normal process may be introduced, in order to ensure the dyeing of an even colour, *i.e.*, free from such irregularities as cloudiness, streaks, &c., which may be due to the quality of the material or to the special properties of the Acid Colour employed. Materials of a firm, close texture, also the existence of a strong affinity between fibre and colouring matter, are not conducive to the dyeing of even colours, or to a satisfactory penetration of the material. Some Acid Colours dye even colours without any difficulty; others, however, do not. The addition of sodium sulphate to the dyebath acts beneficially by causing less sulphuric acid to be attracted by the wool, so that its action is moderated; the dyeing therefore proceeds more slowly and regularly, and a more equal distribution and better absorption of the colouring matter takes place. Other devices to obtain even colours are: the use of old dye-liquors, a diminished amount of acid, the employment of weaker acids, *e.g.*, acetic acid or ammonium acetate, and the entering of the material at a low temperature.

In the application of so-called Alkali Blue the process of dyeing in an acid bath is impossible, owing to the insolubility of the colour-acid in an acid solution. Wool and silk, however, possess an affinity for the alkali salt of the colouring matter in neutral or alkaline solution, hence these fibres are dyed with the addition of about 5 per cent. borax; the material acquires only a pale colour, that of the alkali salt, in this dyebath, but by passing the washed material into a cold or tepid dilute solution of sulphuric acid a full bright blue colour is developed, due to the liberation of the colour-acid within the fibre. In the case of other Acid Colours, *e.g.*, Chromotrope, Chrome Brown, Chromogen, Alizarin Yellow, &c., the dyeing in an acid bath is followed by a treatment with a boiling solution of bichromate of potash, alum, or chromium fluoride, whereby the colouring matter on the fibre is changed into insoluble oxidation products or colour-lakes. This operation of developing or fixing the colour is effected either in the same bath at the end of the dyeing operation, or in a separate bath. See also *Artificial Mordant Colours*.

When dyeing with certain Acid Colours, *e.g.*, Eosine, Phloxine, and other allied bright pink colouring matters derived from resorcinol, the use of sulphuric acid as an assistant must be avoided, since the colours would thereby be rendered paler and duller, and only acetic acid must be employed.

The properties of the dyes obtained with the Acid Colours are extremely varied. Many are fugitive to light; on the other hand, many are satisfactorily fast, some even being very fast in this respect. As a rule, they do not withstand the operations of milling and scouring very well, hence Acid Colours are generally unsuitable for tweed yarns, or for loose wool. They are largely employed, however, in dyeing other varieties of woollen yarn, silk yarn, union fabrics, dress materials, leather, &c. Previous to the discovery of the coal-tar colours, very few Acid Colours were known, the most important one being Indigo Extract. Prussian Blue as applied to wool may also be regarded as belonging to this class, also the purple dyestuff known as Orchil or Cudbear.

The following list includes some of the more important Acid Colours now in use, arranged according to the colour they yield in dyeing:—

*Red.*—Wool Scarlet, Brilliant Scarlet, Erythrine, Brilliant Croceïn, Violamine G, Scarlet 3 R, Crystal Scarlet, New Coccine, Chromotrope 2 R, Azo Acid Magenta, Victoria Scarlet, Xylidine Scarlet, Palatine Scarlet, Biebrich Scarlet, Pyrotine, Orchil Red, Milling Red, Azo Carmine, Acid Magenta, Fast Acid Violet A 2 R, Naphthylamine Red, Fast Red, Claret Red, Eosine, Erythrosine, Rose Bengal, Phloxine, Cyanosine.

*Orange.*—Diphenylamine Orange, Methyl Orange, Naphthol Orange, Croceïn Orange, Brilliant Orange, Orange G, Orange N, Mandarin G R.

*Yellow.*—Picric acid, Naphthol Yellow S, Fast Yellow, Brilliant Yellow S, Azoflavine, Metanil Yellow, Resorcine Yellow, Tartrazine, Quinoline Yellow, Milling Yellow, Azo Yellow, Victoria Yellow, Brilliant Yellow S.

*Green.*—Acid Green, Guinea Green, Fast Green, Patent Green.

*Blue.*—Alkali Blue, Soluble Blue, Opal Blue, Hoechst New Blue, Patent Blue, Ketone Blue, Cyanine, Thiocarmine, Fast Blue, Induline, Violamine 3 B, Azo Acid Blue, Wool Blue, Indigo Extract.

*Violet.*—Acid Violet, Red Violet, Regina Violet, Formyl Violet, Violamine B, Fast Violet.

*Brown.*—Fast Brown, Naphthylamine Brown, Acid Brown, Resorcine Brown, Azo Brown, Chrome Brown, Chromogen.

*Black.*—Naphthol Black, Azo Black, Wool Black, Naphthylamine Black, Jet Black, Anthracite Black, Victoria Black, Azo Acid Black, Brilliant Black.

**Basic Colours.**—These colouring matters are the salts of organic colour-bases, their name being derived from the fact that their dyeing power entirely resides in the basic part of the salt. In the free state the bases are colourless and insoluble, but in combination with acids they form salts which are coloured and for the most part soluble in water. They are usually sold in the form of powder or crystals, the latter exhibiting frequently a beautiful metallic lustre. *Wool* and *silk* are dyed in a neutral bath, *i.e.*, without any addition, the material not requiring any previous preparation. During the dyeing operation the animal fibres appear to play the part of an acid, for they decompose the colouring matter and unite with the colour-base to form an insoluble coloured salt or lake, while the acid of the colouring matter is liberated and remains in solution. Although, as a rule, a neutral dyebath is employed in dyeing wool, a slight addition (2 per cent.) of soap is sometimes made in order to give a brighter colour, while in other cases, *e.g.*, with Victoria Blue, the dyebath must of necessity be

made distinctly acid with acetic or sulphuric acid. Silk is usually dyed in a bath containing "boiled-off liquor" (*i.e.*, the spent soap-liquor from the operation of scouring) neutralized or slightly acidified with acetic or tartaric acid. For a full colour use 2 or 3 per cent. colouring matter, enter the wool at a low temperature, heat gradually to near the boiling-point in the course of $\frac{3}{4}$ hour, and continue dyeing for $\frac{1}{4}$ hour. Owing to the slight solubility of many Basic Colours, it is important to take the precaution of filtering the colour solution into the dyebath through a flannel filter, also to neutralize the alkalinity of calcareous water with a little acetic acid, to prevent decomposition of the colouring matter and precipitation of the colour-base.

Unlike the animal fibres, *cotton* has little or no affinity for the Basic Colours; hence the cotton dyer makes use of the fact that cotton has a natural attraction for tannic acid, and that the latter forms insoluble lakes with the bases of Basic Colours. Previous to dyeing, the cotton is prepared with tannic acid by steeping in a cold solution of the latter for one or two hours; it is then worked for half to one hour in a cold solution of tartar-emetic or stannic chloride, so that the tannic acid absorbed by the fibre may be fixed upon it as insoluble tannate of antimony or tin. Although the tannic acid is thus united with metallic oxide, it still has the power of attracting the base of the colouring matter, and there is fixed upon the fibre an insoluble colour-lake, namely, a tannate of antimony and colour-base, which constitutes the dye. In this process the tannic acid is called the *mordant*, the tartar-emetic acts as the *fixing-agent* for the tannic acid, and the cotton as finally prepared for dyeing is said to be *mordanted*. The proportions employed, reckoned on the weight of cotton, may vary from 2 to 10 per cent. tannic acid, or the equivalent in a decoction of sumach, myrabolams, or other tannin matter, and $\frac{1}{2}$ to 3 per cent. tartar emetic. After mordanting and fixing of the mordant, the cotton is well washed and dyed in the cold or at 60° C. for $\frac{1}{2}$ to 1 hour with the necessary colouring matter. Applied in this manner, Basic Colours are moderately fast to soap, but not to the action of light.

Another method of mordanting cotton for dyeing with the Basic Colours is to impregnate the fibre for a few minutes with a warm solution of soap, or of so-called sulphated-oil (1 ℔ per gallon), then dry and work for $\frac{1}{2}$ hour in a cold solution of aluminium acetate ($\frac{1}{10}$ gallon at 1·045° sp. gr. to 20 gallons water), and finally rinse in water. The cotton is thus mordanted or prepared with a substance analogous to oleate of alumina, in which the oleic acid acts as the real mordant and combines with the base of the colouring matter subsequently applied, while the alumina acts as the fixing-agent for the oleic acid. The ultimate compound fixed upon the dyed fibre is an oleate of alumina and colour-base. The dyes thus obtained are brighter than the colours dyed on tannin mordant, but they are not so fast to soap, and are also fugitive to light.

*Linen* is dyed in the same manner as cotton. Jute is dyed without any previous preparation, since it behaves like a tannin-mordanted fibre, attracting the Basic Colours direct.

The Basic Colours, to which class most of the earlier coal-tar colours belonged, are remarkable for their great colouring power, and in most cases for the brilliancy of the colours they yield. With the exception of certain dark colours, they are fugitive to light. It is interesting to note that only one vegetable colouring matter is at present recognized as belonging to this class, namely, the yellow dyestuff Barberry bark and root (*Berberis vulgaris*), which contains the organic base berberine.

The following is a list of the more important Basic Colours derived from coal-tar:—

*Red.*—Magenta, Safranine, Rhodamine, Pyronine Red, Magdala Red.

*Orange.*—Chrysoïdine, Phosphine, Acridine Orange, Tannin Orange.

*Yellow.*—Auramine, Benzoflavine, Thioflavine T.

*Green.*—Malachite Green, Emerald Green, Imperial Green, China Green, Brilliant Green, Victoria Green, Diamond Green, Methylene Green, Azine Green.

*Blue.*—Methylene Blue, Toluidine Blue, Thionine Blue, Indamine Blue, Victoria Blue, Night Blue, Nile Blue, Turquoise Blue, Marine Blue, Indoïne Blue, Induline, Nigrosine, Meldola Blue, Metamine Blue, Muscarine, Capri Blue, Basle Blue, Indazine, Metaphenylene Blue, Paraphenylene Blue, Toluylene Blue, Indigene, Indol Blue, Diphene Blue.

*Violet.*—Methyl Violet, Crystal Violet, Ethyl Purple, Methylene Violet, Mauve, Paraphenylene Violet, Rhoduline Violet.

*Brown.*—Bismarck Brown.

*Black.*—Fast Black.

*Grey.*—Methylene Grey, Nigrisine, New Grey.

**Direct Colours.**—The characteristic feature of the dyestuffs belonging to this class is that they dye cotton "direct"—*i.e.*, without the aid of mordants. Three distinct series of colouring matters of this group may be distinguished—namely, *Benzidine Colours, Janus Colours*, and *Sulphide Colours.*

(*a*) BENZIDINE COLOURS.—The colours of this class are frequently called the Substantive Cotton Colours, Direct Cotton Colours, Benzo Colours, Diamine Colours, Congo Colours. Considered from the chemical point of view, they are alkali salts of sulphonated tetrazo colours obtained by azotizing certain diamido compounds, *e.g.*, benzidine, diamido-stilbene, &c., and uniting the product thus obtained with various amines or phenols. The first colouring matter of this class was the so-called Congo Red, discovered in 1884, and since that time a very great number have been introduced which yield almost every variety of colour. The method of dyeing *cotton* consists in merely boiling the material in a suitably concentrated solution of the dyestuff, when the cotton absorbs and retains the colouring matter by reason of a special natural affinity. The addition of 1 to 3 oz. sodium sulphate and $\frac{1}{12}$ to $\frac{1}{3}$ oz. carbonate of soda per gallon gives deeper colours, since it diminishes the solubility of the colouring matter in the water and increases the affinity of the cotton for the colouring matter. An excess of sodium sulphate is to be avoided, otherwise precipitation of the colouring matter and imperfect dyeing result. With many dyestuffs it is preferable to use $\frac{1}{6}$ to $\frac{1}{3}$ oz. soap instead of soda. On cotton the dyed colours are usually not very fast to light, and some are sensitive to alkali or to acid, but their most serious defect is that they are not fast to washing, the colour tending to run and stain neighbouring fibres. Their fastness to light and washing is, however, greatly improved by a short ($\frac{1}{2}$ hour) after-treatment with a boiling solution of copper sulphate (3 per cent.), with or without the addition of bichromate of potash (1 per cent.). *Wool* and *silk* are dyed with the Direct Colours in the same manner as cotton, or as with the Acid Colours, adding acetic acid to the dyebath. On these fibres the dyed colours are usually faster than on cotton to washing, milling, and light; some are very fast even to light—*e.g.*, Diamine Fast Red, Chrysophenine, Hessian Yellow, &c. Many of the Direct Colours are very useful for dyeing plain shades on union fabrics composed of wool and cotton, silk and cotton, or wool and silk. Owing to the facility of their application, they are also very suitable for use as household dyes.

A few vegetable dyestuffs belong to this class, notably Turmeric, Saffron, Annatto, and Safflower, but they all yield colours which are fugitive to light, and they are now of little importance. *Turmeric* is the underground stem or tuber of *Curcuma tinctoria*, a plant growing abundantly in the East Indies. It dyes cotton, wool, and silk in a bath acidified with acetic acid or alum, yielding a bright yellow colour which is turned brown by alkalis. *Saffron* consists of the stigmata of the flower of *Crocus sativus*, which is grown in Austria, France, and Spain. It dyes a bright orange-yellow colour. *Annatto* is the pulpy mass surrounding the seeds of *Bixa orellana*, a plant which grows in South America—*e.g.*, Brazil, Cayenne, &c. It dyes cotton and silk in an alkaline or soap bath an orange colour, which is turned red by acids. *Safflower* consists of the dried florets of *Carthamus tinctorius*, which is grown in the East Indies, Egypt, and Southern Europe. Cotton is dyed a brilliant pink colour by working it in a cold alkaline (sodium carbonate) extract of the colouring matter, while gradually acidifying the solution with citric acid (lime-juice).

The Direct Colours which are derived from coal-tar products are very numerous indeed; they are largely employed, and occupy a very important position among dyestuffs. The following list includes the principal coal-tar colours of this group:—

*Red.*—Congo Red, Brilliant Congo, Benzopurpurine, Brilliant Purpurine, Deltapurpurine, Diamine Scarlet, Diamine Fast Red, Rosazurine, Salmon Red, Erica, Titan Pink, St Denis Red, Columbia Red, Naphthylene Red, Congo Rubine, Geranine, Brilliant Geranine.

*Orange.*—Congo Orange, Benzo Orange, Toluylene Orange, Mikado Orange, Brilliant Orange, Columbia Orange, Diamine Orange.

*Yellow.*—Chrysamine, Cresotin Yellow, Diamine Yellow, Carbazol Yellow, Chrysophenine, Hessian Yellow, Curcumine Yellow, Thiazol Yellow, Thioflavine S, Oriol, Mimosa Yellow, Columbia Yellow, Cotton Yellow, Chloramine Yellow, Direct Yellow, Diamine Fast Yellow, Diamine Gold.

*Green.*—Benzo Olive, Columbia Green, Benzo Green, Diamine Green.

*Blue.*—Azo Blue, Benzoazurine, Brilliant Azurine, Sulphonazurine, Diamine Blue, Benzo Indigo Blue, Benzo Black Blue, Chicago Blue, Columbia Blue, Erie Blue, Zambesi Blue, Benzo Cyanine, Congo Blue, Diamine Sky Blue, Brilliant Benzo Blue, Benzo Chrome Black Blue.

*Violet.*—Hessian Purple, Congo Corinth, Heliotrope, Congo Violet, Diamine Violet, Hessian Violet, Azo Violet, Benzo Violet, Violet Black, Diamine Bordeaux.

*Brown.*—Benzo Brown, Congo Brown, Toluylene Brown, Diamine Brown, Cotton Brown, Hessian Brown, Terra Cotta, Mikado Brown, Catechu Brown, Wool Brown, Columbia Brown, Zambesi Brown, Benzo Chrome Brown, Direct Fast Brown, Direct Bronze Brown, Chloramine Brown.

*Black.*—Diamine Black, Columbia Black, Nyanza Black, Tabora Black, Zambesi Black, Chromanil Black, Benzo Black, Benzo Fast Black, Direct Blue Black, Pluto Black, Oxy Diamine Black, Diamine Jet Black.

*Grey.*—Benzo Grey, Benzo Black, Azo Mauve, Diaminogene, Neutral Grey.

(*b*) Janus Colours.—These comprise a small series of azo colours of a strongly basic character, which possess the unusual property of dyeing cotton in an acid bath. Since they also dye wool and silk under the same conditions, they may be employed for dyeing plain shades on wool, silk, and cotton union fabrics. The material is entered into the dyebath at a low temperature, which is gradually raised to the boiling-point. The necessary additions to the dyebath are 1 to 3 per cent. colouring matter, 2 per cent. sulphuric acid, and 5 to 20 per cent. sodium sulphate. The colours include Janus Red, Janus Yellow, Janus Green, Janus Blue, Janus Brown, Janus Bordeaux, Janus Grey, and Janus Black.

(*c*) Sulphide Colours.—These dyestuffs, which are also called Sulphine Colours and Thiosulphate Colours, are only suitable for dyeing the vegetable fibres. The dyestuff Cachou de Laval, discovered in 1873, was the first member of this group, and was obtained by melting a mixture of sodium sulphide and various organic substances—*e.g.*, bran, sawdust, &c. In recent years several other dyestuffs have been added to the list, namely, grey, blue, green, brown, and especially black colours, by submitting certain definite amido compounds to a similar treatment with sodium sulphide or sodium thiosulphate, and subsequent oxidation. The mode of dyeing with these colours is based on the fact that they are soluble in an alkaline reducing agent, and if the cotton is impregnated with the solution, subsequent oxidation develops the colour and fixes it upon the fibre in an insoluble condition. The material is boiled for about one hour in a solution of the colour (10 to 15 per cent.), with the addition of sodium carbonate (1 to 10 per cent.), common salt (10 to 20 per cent.), and sodium sulphide (2 to 20 per cent.); it is then washed quickly in water, and developed for half an hour in a boiling bath containing 2 to 5 per cent. of some metallic salt—*e.g.*, bichromate of potash, copper sulphate, chrome alum, &c. A final washing with water containing a little caustic soda to remove acidity is important. The sulphide colours are remarkable for their fastness to light, alkalis, acids, and washing, but unless proper care is exercised the cotton is apt to be tendered.

The following list includes most of the colours of this class:—

*Green.*—Pyrogene Green, Italian Green.

*Brown.*—Pyrogene Brown, Pyrogene Yellow, Cachou de Laval, Thiocatechine, Katigene Black Brown.

*Grey and Black.*—Pyrogene Grey, Vidal Black, Immedial Black, Katigene Black, Anthraquinone Black, St Denis Black, Amidazol Black, Cross Dye Black, Clayton Fast Black, Eclipse Black, Carbide Black, Thiogene Black, Sulphaniline Black, Sulfogene Black, Pyrogene Black.

At the present time (1902) this class of colours is continually increasing in number, and for certain purposes in cotton dyeing the group is already becoming important.

**Developed Colours.**—This group includes certain azo colours which are developed or produced upon the fibre itself (usually *cotton*) by the successive application of their constituent elements. It may be conveniently divided into the following sub-groups:—Insoluble Azo Colours, Primuline Colours, Developed Direct Colours, Benzo Nitrol Colours.

(*a*) The Insoluble Azo Colours are produced as insoluble coloured precipitates by adding a solution of a so-called diazo compound to an alkaline solution of a phenol, or to an acid solution of an amido compound. The necessary diazo compound is prepared by allowing a solution containing nitrous acid to act upon a solution of an amido-base—*e.g.*, aniline. It is desirable to keep the solutions cool with ice, owing to the very unstable nature of the diazo compounds produced. The colour obtained varies according to the particular diazo compound, as well as the amine or phenol employed, beta-naphthol being the most useful among the latter. The same coloured precipitates are produced upon the *cotton* fibre if the material is first impregnated with an alkaline solution of the phenol, then dried and passed into a cold solution of the diazo solution. Three operations are therefore necessary when dyeing with these colours: (1) *diazotizing* of the base; (2) *impregnation* of the cotton with the phenol solution; (3) *developing.* As an example, the method of dyeing an orange-yellow colour derived from aniline and beta-naphthol is here given.—*Diazotizing.* Aniline (93 parts) is dissolved in hydrochloric acid (sp. gr. 1·14) (390 parts) and water (200 parts). The solution is cooled with the addition of ice, and a solution of sodium nitrite (75 parts) in water (500 parts) is slowly added with continual stirring. Each base requires a slightly different treatment to ensure the best results.—*Impregnation.* A stock solution of beta-naphthol is prepared by dissolving 14 parts by weight of this substance in 4 parts caustic soda and 50 parts water. This solution is diluted 5 to 10 times with water, according to the depth of colour required, and 1 part soda-ash (sodium carbonate) is then dissolved in 15 to 30 parts of the dilute solution; in order to give a brighter colour, a small amount of sulphated oil is sometimes added. The cotton is well impregnated with this solution, then wrung out and dried quickly.—*Developing.* The naphthol-prepared cotton should be passed as soon as possible into the diazo or developing solution, in order to prevent the cotton from acquiring a brownish hue through oxidation. The orange-yellow colour desired is developed almost immediately, but it is well to continue working the cotton about in the solution for a few minutes. The dyed cotton is squeezed, washed, soaped slightly, and finally rinsed in water and dried. The colours obtained by this method vary according to the particular diazo compound employed. If the aniline used in the foregoing process is replaced by meta-nitraniline, a yellowish-orange colour is obtained; with para-nitraniline, a bright red; with alpha-naphthylamine, a claret-red; with amido-azo-toluene, a brownish red; with benzidine, a dark chocolate; with dianisidine, a dark blue; and so on. The dyed colours are fast to washing and are much used in practice, particularly the Para-nitraniline Red, which serves as a substitute for Turkey-red, although it is not so fast to light as the latter.

(*b*) The Primuline Colours are derived from the yellow dyestuff known as Primuline, which dyes cotton in the same manner as the Direct Colours. The Primuline yellow is fugitive to light and of no practical value, but since the colouring matter is an amido base, the dyed fibre can be diazotized and then developed in solutions of phenols or amines, whereby azo dyes of various hues may be obtained, according to the developer employed; *e.g.*, beta-naphthol develops a bright red colour (Primuline Red), resorcinol develops an orange, phenol a yellow, naphthylamine a brown, &c. The *dyeing* of the Primuline yellow is effected by boiling the cotton for one hour in a solution of Primuline (5 per cent.) and common salt (10 to 20 per cent.). The *diazotizing* operation consists in passing the dyed and rinsed cotton for 5 to 10 minutes into a cold solution of nitrous acid—*i.e.*, a solution of ¾ oz. sodium nitrite per gallon of water, slightly acidified with sulphuric acid. The diazotized material should not be exposed to light, but at once washed in cold water and passed into the developer. The *developing* process consists in working the diazotized material for 5 to 10 minutes in a cold solution of the necessary phenol or amine, and finally washing with water. If the developer employed is an amido compound, the dyed colour will contain a free amido group, and hence the operations of diazotizing and developing may be repeated again and again with the object of obtaining darker shades. The Primuline colours are best adapted for *cotton* dyeing, and the colours obtained are fast to washing and to moderate soaping, but they are not very fast to light.

(*c*) Developed Direct Colours.—If *cotton* is dyed with such Direct Colours as contain free amido groups, the colour can be diazotized on the dyed fibre exactly in the same manner as in the case of Primuline-dyed cotton, and then developed by passing into the solution of an amine or phenol, or by treating it with a warm solution of sodium carbonate. In this manner a new azo dye is produced upon the fibre, which differs from the original one not only in colour, but also by being faster to washing and other influences. A treatment with copper sulphate solution after development is frequently beneficial in rendering the colour faster to light. Some Direct Colours, indeed, are of little value, owing, for example, to their sensibility to acids, until they have been diazotized and developed, the usual developers being beta-naphthol, resorcinol, phenol, and phenylene-diamine.

The following Direct Colours, after being applied to cotton, may be submitted to the above treatment, the colours produced being chiefly blue, brown, and black:—

*Blue.*—Diazurine, Diazo Blue, Diamine Blue, Diaminogene.

*Brown.*—Diazo Brown, Diamine Cutch, Diamine Brown, Cotton Brown.

*Grey and Black.*—Benzo Blue, Diazo Blue Black, Diazo Black, Diamine Black, Diazo Brilliant Black.

(*d*) Benzo Nitrol Colours.—These are certain Direct Colours dyed on *cotton* in the ordinary manner, which are then developed by passing into a diazo solution—*e.g.*, diazotized para-nitraniline, &c. The dyed colour here plays the part of a phenol or amine, and reacts with the diazo compound to produce a new colour. The process is similar to the production of the Insoluble Azo Colours, the beta-naphthol which is there applied to the fibre being here replaced by a Direct Colour. The colour of the latter is rendered much deeper by the process, and also faster to washing and to the action of acids. The dyestuffs recommended for application in the manner described are: Benzo Nitrol Brown, Toluylene Brown, Direct Fast Brown, Pluto Black, Direct Blue Black.

**Mordant Colours.**—The colouring matters of this class include some of the most important dyestuffs employed, since they furnish many colours remarkable for their fastness to light, washing, and other influences. Employed by themselves, Mordant Colours are usually of little or no value as dyestuffs, because, with some exceptions, either they are not attracted by the fibre, particularly in the case of cotton, or they only yield a more or less fugitive stain. Their importance and value as dyestuffs are due to the fact that they act like weak acids and have the property of combining with metallic oxides to form insoluble coloured compounds termed

"lakes," which vary in colour according to the metallic oxide or salt employed. The most stable lakes are those in which the colouring matter is combined with two metallic oxides, a sesqui-oxide and a monoxide—*e.g.*, alumina and lime. In applying colouring matters of this class the object of the dyer is to precipitate and fix these coloured lakes upon and within the fibre, for which purpose two operations are necessary, namely, *mordanting* and *dyeing*.

The *mordanting operation* aims at fixing upon the fibre the necessary metallic oxide or insoluble basic salt, which is called the *mordant*, although the term is also applied to the original metallic salt employed. In the subsequent dyeing operation the mordanted material is boiled with a solution of the colouring matter, during which the metallic oxide attracts and chemically combines with the colouring matter, producing the coloured lake *in situ* on the fibre, which thus becomes dyed. The mode of applying the mordants varies according to the nature of the fibre and the metallic salt employed, the chief mordants at present in use being salts of chromium, aluminium, tin, copper, and iron. The method of mordanting *wool* depends upon its property of decomposing metallic salts, and fixing upon itself an insoluble metallic compound, when boiled in their solutions. This decomposition is facilitated by the heating and by the dilution of the solution, but it is chiefly due to the action of the fibre itself. The exact nature of the substance fixed upon the fibre has not in all cases been determined; probably it is a compound of the metallic oxide with the wool-substance itself, which has the character of an amido-acid. The mordant most largely employed for wool is bichromate of potash, since, besides being simply applied, and leaving the wool with a soft feel, it yields with the various mordant-dyestuffs a large variety of fast colours. The wool is boiled for 1 to 1½ hour in a solution containing 2 to 3 per cent. bichromate of potash on the weight of the wool employed. During this operation the wool at first attracts chromic acid, which is gradually reduced to chromium chromate, so that the mordanted fibre has finally a pale olive-yellow tint. In the dyebath, under the influence of a portion of the dyestuff, further complete reduction to chromic hydrate occurs before it combines with the colouring matter. Not unfrequently certain so-called "assistants" are employed in small amount along with the bichromate of potash—*e.g.*, sulphuric acid, cream of tartar, tartaric acid, lactic acid, &c. The use of the organic acids here mentioned ensures the complete reduction of the chromic acid on the wool to chromic hydrate already in the mordant bath, and the pale greenish mordanted wool is better adapted for dyeing with colours which are susceptible to oxidation—*e.g.*, Alizarin Blue. For special purposes chromium fluoride, chrome alum, &c., are employed. Alum or aluminium sulphate (8 per cent.), along with acid potassium tartrate (cream of tartar) (7 per cent.), is used for brighter colours—*e.g.*, reds, yellows, &c. The object of the tartar is to retard the mordanting process and ensure the penetration of the wool by the mordant, by preventing superficial precipitation through the action of ammonia liberated from the wool; it ensures the ultimate production of clear, bright, full colours. For still brighter colours, notably yellow and red, stannous chloride was at one time largely employed, now it is used less frequently; and the same may be said of copper and ferrous sulphate, which were used for dark colours. *Silk* may be often mordanted in the same manner as wool, but as a rule it is treated like cotton. The silk is steeped for several hours in cold neutral or basic solutions of chromium chloride, alum, ferric sulphate, &c., then rinsed in water slightly, and passed into a cold dilute solution of silicate of soda, in order to fix the mordants on the fibre as insoluble silicates. *Cotton* does not, like wool and silk, possess the property of decomposing metallic salts, hence the methods of mordanting this fibre are more complex, and vary according to the metallic salts and colouring matters employed, as well as the particular effects to be obtained. One method is to impregnate the cotton with a solution of so-called "sulphated oil" or "Turkey-red oil"; the oil-prepared material is then dried and passed into a cold solution of some metallic salt—*e.g.*, aluminium acetate, basic chromium chloride, &c. The mordant is thus fixed on the fibre as a metallic oleate, and after a passage through water containing a little chalk or silicate of soda to remove acidity, and a final rinsing, the cotton is ready for dyeing. Another method of mordanting cotton is to fix the metallic salt on the fibre as a tannate instead of an oleate. This is effected by first steeping the cotton in a cold solution of tannic acid or in a cold decoction of some tannin matter, *e.g.*, sumach, in which operation the cotton attracts a considerable amount of tannic acid; after squeezing, the material is steeped for an hour or more in a solution of the metallic salt, and finally washed. The mordants employed in this case are various—*e.g.*, basic aluminium or ferric sulphate, basic chromium chloride, stannic chloride (cotton spirits), &c. There are other methods of mordanting cotton besides those mentioned, but the main object in all cases is to fix an insoluble metallic compound on the fibre. It is interesting to note that whether the metallic oxide is united with the substance of the fibre, as in the case of wool and silk, or precipitated as a tannate, oleate, silicate, &c., as in the case of cotton or silk, it still has the power of combining with the colouring matter in the dyebath to form the coloured "lake" or dye on the material.

The *dyeing operation* consists in working the mordanted material in a solution of the necessary colouring matter, the dyebath being gradually raised to the boiling-point. With many colouring matters, *e.g.*, with Alizarin, it is necessary to add a small percentage of calcium acetate to the dyebath, and also acetic acid if wool is being dyed. In wool-dyeing, also, the mordanting operation may follow that of dyeing instead of preceding it, in which case the boiling of the wool with dyestuff is termed "stuffing," and the subsequent developing of the colour by applying the mordant is termed "saddening," because this method has in the past been usually carried out with iron and copper mordants, which give dull or sad colours. The method of "stuffing and saddening" may, however, be carried out with other mordants, even for the production of bright colours, and it is now frequently employed with certain alizarin dyestuffs for the production of pale shades which require to be very even and regular in colour. There is still another method of applying Mordant Colours in wool-dyeing, in which the dyestuff and the mordant are applied simultaneously from the beginning; it is known as the "single-bath method." It is only successful, however, in the case of certain colouring matters and mordants, to some of which reference will be made in the following paragraphs.

The Natural Mordant Colours.—It is interesting to note that nearly all the natural or vegetable dyestuffs employed belong to the class of Mordant Colours, the most important of these being included in the following list:—*Madder, Cochineal, Peachwood, Sapanwood, Limawood, Camwood, Barwood, Sanderswood, Old Fustic, Young Fustic, Quercitron Bark, Persian Berries, Weld, Logwood.*

Madder consists of the dried ground roots of *Rubia tinctorum*, a plant of Indian origin. Formerly cultivated largely in France and Holland, it was long one of the most important dyestuffs employed, chiefly in the production of Turkey-red and in calico-printing, also in wool-dyeing. With the different mordants it yields very distinct colours, all fast to light and soap, namely, red with aluminium, orange with tin, reddish brown with chromium, purple and black with iron. Madder contains two closely allied colouring matters, namely, purpurin and alizarin. The latter, which is by far the most important, is now prepared artificially from the coal-tar product anthracene, and has almost entirely superseded madder.

Cochineal is the dried scale-insect *Coccus-cacti*, which lives on certain of the cactus plants of Mexico and elsewhere. The rearing of cochineal was once a large and important industry, and although still pursued, it has seriously declined, in consequence of the discovery of the Azo Scarlets derived from coal-tar. The colouring matter of cochineal, carminic acid, is believed by chemists to be a derivative of naphthalene, but its artificial production has not yet been accomplished. Cochineal dyes a purple colour with chromium mordant, crimson with aluminium, scarlet with tin, and grey or slate with iron. Its chief employment is for the purpose of dyeing crimson, and more especially scarlet, on wool. Crimson is dyed by mordanting the wool with alum and tartar and dyeing in a separate bath with ground cochineal. Scarlet on wool is obtained by the single-bath method, namely, by dyeing the wool with a mixture of stannous chloride (or nitrate of tin), oxalic acid, and cochineal. It is usual to add also a small amount of the yellow dyestuff Flavine in order to obtain a yellower shade of scarlet. The cochineal colours are very fast to light, but somewhat susceptible to the action of alkalis.

Peachwood, Sapanwood, and Limawood are usually referred to as the "soluble red-woods," because of the solubility in water of the colouring principle they contain. They consist of the ground wood of various species of *Cæsalpinia* found in Central America, the East Indies, and Peru. They all yield more or less similar colours with the different mordants—claret-brown with chromium, red with aluminium, bright red with tin, dark slate with iron. Owing to the fugitive character of all the colours to light, these dyewoods are now comparatively little employed in dyeing, being replaced by the Alizarin Colours. All these dyewoods seem to contain the same colouring principle, namely, brazilin, which, either before or during its union with the mordant, is converted by oxidation into the colouring matter brazileïn. The chemical constitution of this substance has recently been definitely established, and it appears to be a member of the $\gamma$-pyrone group of colouring matters, to which several of the natural yellow dyestuffs also belong.

Camwood, Barwood, and Sanderswood represent the so-called "insoluble red-woods," their colouring principles being sparingly soluble even in boiling water. They are obtained from certain species of *Pterocarpus* and *Baphia*, large trees growing in the interior of West Africa. Their general dyeing properties are similar, a claret-brown being obtained with chromium mordant, a brownish red with aluminium, a brighter red with tin, and

purplish brown with iron. Their chief employment is in wool-dyeing, for the production of various shades of brown, being best applied by the "stuffing and saddening" method above described; but since the colours are fugitive to light, they are now very largely replaced by Alizarin. A brown on wool is obtained by first boiling for one to two hours in a decoction of the ground wood (50 per cent.), and then boiling in a separate bath in solution of bichromate of potash (2 per cent.) for half an hour. These dye-woods are also employed by the indigo-dyer, in order to give a brownish ground colour to the wool previous to dyeing in the indigo vat, and thus obtain a deeper, fuller blue. The colouring matters contained in these dyewoods have not been exhaustively examined.

Old Fustic is a yellow dyestuff, and consists of the wood of the dyer's mulberry tree, *Morus tinctoria*, which grows in Cuba, Jamaica, &c. It is still an important and largely used dyestuff, being cheap, and the colours obtained from it being satisfactorily fast to light and other influences. With chromium mordant it yields an olive-yellow or "old-gold" shade; with aluminium, yellow; with tin, a brighter yellow; with iron, an olive-green. It is chiefly employed in wool-dyeing along with other dyestuffs, and furnishes the yellow in compound shades. Two colouring principles exist in Old Fustic, namely, morin and maclurin, the former being the most important, and generally regarded as the true colouring matter.

Young Fustic consists of the wood of the sumach tree, *Rhus cotinus*, which grows in Italy and Southern Europe. Its general dyeing properties are similar to those of Old Fustic, although the various mordants give somewhat different colours, notably the tin mordant, which gives a brilliant orange-yellow. All the colours obtained are very fugitive to light, hence this dyestuff is now of little importance. The colouring matter of Young Fustic is called fisetin.

Quercitron Bark consists of the inner bark of an oak-tree, *Quercus tinctoria*, which grows in the North American States. It dyes somewhat like Old Fustic, but gives with aluminium and tin mordants brighter yellows, for which colours it is chiefly used. The colouring principle of Quercitron Bark is called quercitrin, which by the action of boiling mineral acid solutions is decomposed, with the production of the true colouring matter termed quercetin.

So-called Flavine is a commercial preparation of Quercitron Bark consisting of quercitrin or of quercetin; it is much used by wool-dyers for the production of bright yellow and orange colours. Wool is dyed in single bath by boiling with a mixture of Flavine (8 per cent.), stannous chloride (4 per cent.), and oxalic acid (2 per cent.). Flavine is used in small quantity along with cochineal for dyeing scarlet on wool.

Persian Berries are the dried unripe fruit of various species of *Rhamnus* growing in the Levant. The general dyeing properties are similar to those of Quercitron Bark, the orange colour given with tin mordant being particularly brilliant. The high price of this dyestuff causes its employment to be somewhat limited. The colouring matter of Persian Berries is called xanthorhamnin, which by the action of fermentation and acids yields the true dyestuff rhamnetin.

Weld is the dried plant *Reseda luteola*, a species of wild mignonette, formerly largely cultivated in Europe. Its dyeing properties resemble those of Quercitron Bark, but the yellows with aluminium and tin mordants are much brighter and purer, and also faster to light. It is still used to a limited extent for dyeing a bright yellow on woollen cloth and braid for the decoration of military uniforms. Quite recently the colouring matter of Weld, namely, luteolin, has been prepared artificially, but the process is too expensive to be of practical use.

Logwood is the heart-wood of *Hæmatoxylon campechianum*, a tree growing in Central America. It is the most important natural dyewood at present employed, being largely used for dyeing dark blues and black on silk, wool, and cotton. With chromium and aluminium mordants logwood dyes a dark blue, and even black; with tin, a dark purple; and with iron, black. The colours are only moderately fast to light. On wool the mordant is bichromate of potash, on cotton and silk an iron mordant is employed. Before use by the dyer the logwood is ground and aged or oxidized, by allowing moistened heaps of the ground wood to ferment slightly, and by frequently turning it over to expose it freely to the air. By this means the colouring principle hæmatoxylin which logwood contains is changed into the true colouring matter hæmateïn. The constitution of this colouring matter has been recently discovered; it is very closely allied to the brazilin of Peachwood, Sapanwood, and Limawood, and is also a member of the $\gamma$-pyrone group of colouring matters.

The importance of the above-mentioned natural dyestuffs is gradually diminishing in favour of mordant dyestuffs and others derived from coal-tar. Old Fustic and Logwood are perhaps the most largely used, and may continue to be employed for many years, owing to their comparatively low price.

The Artificial Mordant Colours are well represented by Alizarin, the colouring matter of the Madder root, which was the first natural dyestuff prepared artificially in 1868 from the coal-tar product anthracene. For this reason many of these colours are frequently referred to as the Alizarin Colours. At the present time, however, there are numerous Mordant Colours which are prepared from other initial materials than anthracene; they are not chemically related to Alizarin, and for these the term Alizarin Colours is therefore inappropriate. The property, which Mordant Colours possess in common, of combining with metals and producing lakes, which readily adhere to the fibre, depends upon their chemical constitution, more particularly upon the general and relative position in the molecule of certain side atomic groups. In Alizarin there are, for example, two characteristic hydroxyl groups (OH) occupying a special (ortho) position in the molecule—*i.e.*, they are next to each other, and also next to one of the so-called ketone groups (C : O). In other Mordant Colours there are carboxyl (COOH) as well as hydroxyl groups, which are all-important in this respect. In addition to this, the general dyeing property is influenced by the constitution of the molecule itself, and by the presence of other side-groups, *e.g.*, $NH_2$, $HSO_3$, &c., which modify the colour as to solubility or hue. Hence it is that the members of this group, while possessing the mordant-dyeing property in common, differ materially in other points. Some, like Alizarin, are not in themselves to be regarded as colouring matters, but rather as colouring principles, because they only yield useful dyes in combination with metallic oxides. According to their constitution, these may yield one or many colours with the various metallic oxides employed, and they are used for cotton as well as for wool and silk. Other Mordant Colours, *e.g.*, many of the Direct Colours and others, are capable of dyeing either the vegetable or animal fibres without the aid of a mordant; they are fully developed colouring matters in themselves, and possess the mordant dyeing property as an additional feature, in consequence of the details of their chemical constitution, to which reference has been made in the foregoing paragraphs. As a rule these yield, at most, various shades of one colour with the different oxides, and are only suitable for the animal fibres, particularly wool.

In the following list, the most important artificial Mordant Colours are arranged according to the colour they give in conjunction with the aluminium mordant, unless otherwise indicated. Those which dye the animal fibres, even without mordants, are given in italics; some are Direct Colours possessing mordant-dyeing properties, others are sulphonic acid derivatives of Alizarin Colours, suitable for wool but not for cotton.

*Red.*—Alizarin, Anthrapurpurin, Flavopurpurin, Purpurin, Alizarin Bordeaux, Alizarin Garnet R, Alizarin Maroon, Alizarin S, *Cloth Red*, *Diamine Fast Red*, *Anthracene Red.*

*Orange and Yellow.*—Alizarin Orange, Alizarin Orange G, Alizarin Yellow paste, Alizarin Yellow A, Alizarin Yellow C, Anthracene Yellow, Galloflavin, *Fustin*, *Alizarin Yellow GG*, *Alizarin Yellow R*, *Diamond Flavin G*, *Chrome Yellow D*, *Crumpsall Yellow*, *Fast Yellow*, *Diamond Yellow*, *Benzo Orange R*, *Cloth Orange*, *Carbazol Yellow*, *Chrysamine.*

*Green.*—Cœruleïn, Cœruleïn S, Alizarin Green S, Fast Green (Fe), Naphthol Green (Fe), Dioxin (Fe), Gambine (Fe), *Azo Green*, *Gallanil Green*, *Alizarin Green G and B*, *Acid Alizarin Green*, *Alizarin Cyanine Green*, *Diamond Green.*

*Blue.*—Alizarin Blue, Alizarin Blue S, Alizarin Cyanine, Anthracene Blue, Brilliant Alizarin Blue, Alizarin Indigo Blue S, *Acid Alizarin Blue*, *Brilliant Alizarin Cyanine*, *Alizarin Saphirole*, *Gallanilide Blue*, *Delphine Blue*, *Gallamine Blue*, *Celestine Blue*, *Chrome Blue*, *Gallazine A*, *Phenocyanine*, *Coreïne.*

*Purple and Violet.*—Galleïn, *Gallocyanine*, *Chrome Violet.*

*Brown.*—Anthracene Brown, Chromogen, *Cloth Brown*, *Diamond Brown*, *Alizarin Brown*, *Fast Brown.*

*Black.*—Alizarin Black, *Diamond Black*, *Alizarin Blue Black*, *Alizarin Cyanine Black*, *Alizarin Fast Grey*, *Chromotrope.*

A brief description of the application of a few of the more important of the above colouring matters will suffice.

Alizarin, Anthrapurpurin, and Flavopurpurin give somewhat similar shades with the different mordants, namely, brown with chromium, red with aluminium, orange with tin, and purple with iron mordant.

In *wool*-dyeing they are applied along with other Mordant Colours on chromium mordant for the production of a large variety of compound shades, browns, drabs, greys, &c., the presence of acetic acid in the dyebath being advantageous. When alum and tartar mordant is employed, for the production of reds, it is necessary to add a small amount (4 per cent.) of calcium acetate to the dyebath, in order to neutralize the strong acidity of the mordanted wool, and to furnish the calcium of the colour-lake fixed upon the fibre, which is regarded as an aluminium-calcium compound of the colouring matter.

In *cotton*-dyeing the above colouring matters are chiefly used for the production of so-called Turkey-red, a colour remarkable for its brilliancy and its fastness to light and soap. These properties are due to the preparation of the cotton with oil, in addition to the ordinary mordanting and dyeing, whereby there is fixed on the fibre a permanent and stable lake, in which aluminium and calcium are combined with Alizarin and some form of oxy-fatty acid. In the older processes employed, the preparation of the cotton with oil was effected by passing the material several times through emulsions of olive-oil and potassium carbonate solution; at a later date, and even now in the case of cloth, the cotton is first impregnated with hot oil (Steiner's process), then passed through solutions of alkali carbonate. After the preparation with oil or oil-emulsions, the cotton is "stoved," *i.e.*, heated for several hours in special chambers or stoves to a temperature of about 70° C., during which operation the oil is decomposed and oxidized and becomes indelibly attached to the fibre. The oil-prepared cotton is steeped in cold solutions of basic aluminium sulphate or acetate, washed, dyed with Alizarin, and finally boiled for several hours with soap solution under pressure in order to brighten the colour. In the more recent and much more expeditious "sulphated-oil process," castor-oil is employed instead of olive-oil, and before use it is submitted to a treatment with sulphuric acid, the sulphated oil thus obtained being finally more or less neutralized with alkali. The cotton is impregnated with this sulphated-oil solution, dried, mordanted with aluminium acetate, dyed, dried, steamed, and soaped. The operation of steaming plays an important part in brightening and fixing the colour-lake on the fibre. In these and all other Turkey-red processes, the oil, probably in the form of an oxy-fatty acid, acts as a fixing agent for the aluminium and enters into the composition of the red lake, imparting to it both brilliancy and permanency.

Alizarin S is a sulphonic acid derivative of Alizarin, and since it is much more soluble, it readily yields level colours. Silk is dyed in a similar manner to wool, the fibre being mordanted by the ordinary methods and then dyed in a separate bath.

Diamine Fast Red is applied to cotton as a Direct Colour, with the addition of soda or soap to the dyebath. By treating the dyed colour with a solution of fluoride of chromium, its fastness to washing is materially increased. Wool is dyed in a similar manner, sodium sulphate being added to the dyebath, and the dyed colour treated with fluoride of chromium or bichromate of potash. The colour is so extremely fast to light and to milling on wool that it may well serve as a substitute for Alizarin.

Alizarin Orange is employed in the same manner as Alizarin. In wool-dyeing it is usually applied on chromium mordant for browns and a variety of compound shades in combination with other Alizarin Colours and dyewood extracts, less frequently on aluminium mordant.

Galloflavin is used in wool and silk dyeing on chromium mordant as a substitute for Fustic and other yellow dyewoods, to furnish the yellow part of compound shades.

The Alizarin Yellows, R and GG, Anthracene Yellow, Diamond Flavine, Chrome Yellow, Diamond Yellow, Carbazol Yellow, Chrysamine, &c., are Direct Colours with mordant-dyeing properties. They also serve as substitutes for Fustic in wool or silk dyeing, and are dyed either on a chromium mordant, or first in an acid bath and afterwards saddened with bichromate of potash.

Cœruleïn is employed in dyeing wool, silk, or cotton with aluminium or chromium mordants, either as a self-colour or for compound shades. With aluminium mordant the colour is a moderately bright green, more particularly on silk; with chromium mordant, an olive-green. Cœruleïn S is the more soluble bisulphite compound of the ordinary Cœruleïn. It is applied in the same manner, care being taken, however, to dye for some time (one hour) at a temperature not exceeding 60° C. until the bath is nearly exhausted, and then only raising the temperature to the boiling-point. Without this precaution Cœruleïn S is decomposed, and the ordinary insoluble Cœruleïn is precipitated. The colours obtained are very fast to light.

Fast Green, Dioxine, and Gambine are chiefly of use in calico-printing and in wool-dyeing. With iron mordant they yield olive-greens, which on wool are extremely fast to light. Cotton is impregnated with ferrous acetate, dried, aged, and fixed with silicate of soda, then dyed in a neutral bath. Wool is mordanted with ferrous sulphate and tartar (3 per cent. of each) and dyed in a neutral bath.

Acid Alizarin Green, Alizarin Cyanine Green, and Diamond Green, all dye wool direct in a bath acidified with acetic or sulphuric acid, and the dyed colour may be afterwards fixed or saddened with bichromate of potash, or they may be dyed on chromium-mordanted wool. The first method is very useful for pale shades, since the colours are very level or regular.

Alizarin Blue is a dark blue dyestuff which, owing to the fastness of the colours it yields, has for many years been regarded as a worthy substitute for Indigo in wool-dyeing. It is applied in the same manner as Alizarin, the chromium mordant being alone employed. Alizarin Blue S is the soluble sodium bisulphite compound of Alizarin Blue; it corresponds, therefore, to the above-mentioned Cœruleïn S, and in its application the same precautions as to the temperature of the dyebath are necessary. The fastness of the dyed colours to light, milling, and acid satisfy the highest requirements.

Alizarin Cyanine, Anthracene Blue, and Brilliant Alizarin Blue were discovered later than the above-mentioned Alizarin Blues, and, owing to their greater solubility and other advantages, they have largely replaced them as substitutes for Indigo. They are dyed on chromium-mordanted wool, silk, or cotton, and yield dark purplish or greenish blues, according to the particular brand employed. The fastness of the dyed colours to light, and general durability, are very satisfactory, but in fastness to milling and acids they are to some extent inferior to Alizarin Blue.

Celestine Blue and Chrome Blue dye purplish blue and bright blue respectively, and are dyed in the ordinary way upon a chromium mordant. The colours they yield are inferior to the Alizarin Colours in fastness to light, but on account of their clear shades they are often used for brightening other colours.

Brilliant Alizarin Cyanine and Alizarin Saphirole are true Alizarin Colours, and possess the same fastness to light as other colours of this class. Unlike most of the Alizarin Colours, they are capable of dyeing wool satisfactorily without the aid of a metallic mordant—namely, with the addition of sulphuric acid to the dyebath, in the same manner as the Acid Colours. If necessary, the dyed colours may be treated with bichromate of potash. The colours thus produced are very fast to light and very level, hence these dyestuffs are valuable in the production of the most delicate compound shades, such as drabs, slates, greys, &c., which are desired to be fast to light. Alizarin Saphirole dyes clear blue, the colour produced being much more brilliant even than those of Brilliant Alizarin Cyanine.

Galleïn, Gallocyanine, and especially Chrome Violet, dye somewhat bright purple shades, and are hence frequently employed for brightening other colours, but they are only moderately fast to light. They are applied in the usual manner on a chromium mordant.

Anthracene Brown is largely employed in the production of compound shades. It dyes a dark, somewhat reddish, brown on chromium mordant, the colour being very even and extremely fast to light.

Chromogen is a greyish white powder, readily soluble in water, with a pale brown colour. It is attracted and absorbed by wool in a boiling acid bath; at this stage the wool remains colourless, but by subsequently boiling it with a little bichromate of potash in the same or in a separate bath the absorbed chromogen is oxidized and the brown colour is developed.

Alizarin Black is dyed on chromium mordant in the same manner as Alizarin, and is used as a self-colour or in combination with other Alizarin Colours.

Diamond Black and the following three colours mentioned in the list are very useful for dyeing good blacks on wool, fast to light and acids. The wool is first dyed with the addition of acetic and finally sulphuric acid. When the dyebath is exhausted, bichromate of potash (2 per cent.) is added, and boiling is continued for half an hour longer.

Chromotrope, of which there are several brands, is an Acid Colour which is applied to wool in an acid bath in the usual manner. The red or purple colours thus obtained are saddened in the same bath with bichromate of potash and changed into black, the colouring matter being oxidized and simultaneously combined with chromium.

**Miscellaneous Colours.**—Under this head there may be arranged a few dyestuffs which, although capable of inclusion under one or other of the foregoing groups, it is more convenient to treat of separately. Indigo, Aniline Black, and Catechu, for example, might be placed in the class of Developed Colours, since they are all developed on the fibre, and indeed by the same method—namely, by oxidation.

Indigo is one of our most important blue dyestuffs, which has been employed from the earliest times. It may be obtained from various plants, the chief of which are the European woad-plant *Isatis tinctoria*, the Chinese and Japanese indigo-plant *Polygonum tinctorium*, and the indigo-plant of India, *Indigofera tinctoria*, &c., but the chief supply is obtained from the last-mentioned plant, which is largely cultivated in India. Curiously enough, the living plant contains no indigo, but an indigo-yielding substance called indican, which is converted into indigo during the process of extraction by the joint influence of fermentation and oxidation, there being simultaneously separated a sugar product called Indiglucine. In India the fresh plants are steeped in large tanks containing water; fermentation soon begins, and lasts for about fifteen hours, when it subsides; at this stage a clear yellow liquor is drawn off into shallow tanks, and there agitated in contact with the air, whereby the indigo is produced and precipitated as

a dark blue powder. After drawing off the supernatant liquid, the sediment of indigo is boiled with water to prevent further destructive fermentation, and then collected on filtering frames, the drained pasty indigo being finally pressed; the press-cakes are cut into the form of cubes, which are finally dried in open-air sheds. In 1878 Professor Baeyer succeeded in preparing indigo by artificial means from the coal-tar product toluene. Two years later he devised another method, the initial substance being cinnamic acid. This process, known as the "propiolic-acid" method, was for a brief period carried out on a commercial scale, the product "propiolic acid" being employed by calico-printers and only converted by them into indigo-blue during the process of application. Since then, chemists have found it possible to prepare artificial indigo by various methods, but few of these have given any great promise of commercial success. In 1890, however, Heumann astonished the chemical world by preparing indigo from such simple materials as aniline, acetic acid, chlorine, and alkali, the immediate mother-substance, prepared from the first three, being so-called phenyl-glycocoll, which requires simply to be melted with alkali and dissolved in water to yield the indigo. Difficulties as to the yield of indigo obtained soon caused this process to be abandoned in favour of one closely akin to it, in which the carboxylic acid derivative of phenyl-glycocoll is similarly melted with alkali. This substance is derived by successive stages from anthranilic acid, phthalimide, phthalic acid, and finally naphthalene. This last-mentioned substance, which has now therefore become the initial material, is obtained in large quantity by the direct distillation of coal-tar. Since 1897 the manufacture of indigo from naphthalene on a commercial scale has been carried on by one of the large German colour-manufacturing firms (Badische Anilin and Soda Fabrik) with every appearance of success, so much so that the indigo-planters of India have been compelled to adopt improved methods in order to reduce the cost of production. At the present time natural and synthetic indigo are entering upon a period of commercial competition with each other, and time alone can show which can be produced at the lowest price and be ultimately successful in the conflict. It is well to emphasize the fact that the colouring matter indigotin is identical in both the artificial and natural products, but in the latter it is accompanied by other substances, notably indigo-red (indirubin), indigo-brown, and indigo-gluten. The first is a dyestuff similar in general properties to indigo-blue, but yielding purple shades instead of blue; the rest may be regarded as impurities. An exaggerated importance has been attached by some dyers to the presence of these accompanying substances in natural indigo, as giving fulness and depth to the dyed colour, but these effects may also be obtained with artificial indigo by employing suitable means; and in the case of indigo-red this, too, can be made artificially if required.

As to the methods of application in dyeing, they are the same with both dyestuffs, and these may be now briefly described. Indigo, being insoluble in water, would be of no use in dyeing if it were not capable of being rendered soluble. This is effected in two ways, corresponding to which there are two methods of dyeing with indigo. One method consists in dissolving the indigo in very strong sulphuric acid, whereby it is converted into indigotin-disulphonic acid (Indigo Extract), which is readily soluble in water. This substance belongs to the group of Acid Colours; hence it is applied to the animal fibres, wool and silk, by boiling in a solution of the colouring matter slightly acidified with sulphuric acid. The second and most important method is based on the fact that under the influence of reducing agents (*i.e.*, substances capable of yielding nascent hydrogen) indigo-blue is changed into indigo-white, which is soluble in alkali, the solution thus obtained being called a "vat." If textile materials are steeped in a clear yellow solution of the reduced indigo and then exposed to air, the indigo-white absorbed by the fibre is oxidized and reconverted into indigo-blue within and upon the fibre, which thus becomes dyed blue; this is the so-called "indigo-vat" method of dyeing. Comparing the two methods, the "indigo-extract method" is only applicable to the animal fibres, and although it gives brighter colours, they are fugitive to light and are decolorized by washing with alkaline solutions; the "vat method" is applicable to all fibres, and gives somewhat dull blues, which are very fast to light, washing, &c.

*Cotton* is dyed by means of the "*lime and copperas vat*," the "*zinc powder vat*," or the "*hydrosulphite vat*." In the first-mentioned vat the ingredients are quicklime, ferrous sulphate, and indigo; the lime decomposes the ferrous sulphate and precipitates ferrous hydrate; this quickly absorbs oxygen from the water present, with the liberation of hydrogen, which at once combines with the indigo to form indigo-white, this in turn dissolving in the excess of lime present. The ingredients of the zinc powder vat are zinc powder, lime, and indigo; in the presence of the lime and indigo the zinc takes up oxygen from the water, liberating the hydrogen necessary to reduce the indigo, as in the previous vat. The constituents of the hydrosulphite vat are hydrosulphite, or more correctly hyposulphite of soda, lime, and indigo. The requisite hyposulphite of soda is prepared by allowing zinc powder (13 lb) to act upon a cold concentrated solution of bisulphite of soda (17 gallons of sp. gr. 1·225), taking care to avoid, as much as possible, access of air and any heating of the mixture, to prevent decomposition. The solution thus obtained is thoroughly neutralized by the addition of lime; and after settling, the clear liquor is used for the vat, along with indigo and lime. Here again the hyposulphite takes up oxygen from the water and liberates the necessary hydrogen. It is found convenient to prepare, in the first instance, a very concentrated standard of reduced indigo, and to add as much of this to the dye-vat as may be required, along with lime and a little hyposulphite of soda. The advantages of this vat are that it is easily prepared and that there is very little sediment; moreover, it can be employed in dyeing wool as well as cotton, and it is now very generally in use. The vat usually employed for dyeing *wool* is the so-called "woad vat," which differs from the foregoing in that the hydrogen necessary to reduce the indigo and bring it into solution is furnished, not by the action of chemical agents, but by means of fermentation. The ingredients of the woad-vat are indigo, woad, bran, madder, and lime. The woad here employed is prepared by grinding the leaves of the woad plant (*Isatis tinctoria*) to a paste, which is allowed to ferment and then partially dried. It serves as the ferment to excite lactic and butyric fermentation with the aid of the bran and madder, the necessary hydrogen being thus evolved. Excessive fermentation is avoided by making timely additions of lime; sluggish fermentation is accelerated by additions of bran and slightly raising the temperature. When the reduction and complete solution of the indigo is effected, the vat is allowed to settle, and the woollen material is immersed and moved about in the clear liquor for half an hour to two hours, according to the shade required, then squeezed and exposed to the air in order to develop the blue colour on the fibre.

Aniline Black differs from other dyes in that it is not sold as a ready-made dyestuff, but is produced *in situ* upon the fibre by the oxidation of aniline. It is chiefly used for cotton, also for silk and cotton-silk union fabrics, but seldom or not at all for wool. Properly applied, this colour is one of the most permanent to light and other influences with which we are acquainted. One method of dyeing cotton is to work the material for about two hours in a cold solution containing aniline (10 parts), hydrochloric acid (20 parts), bichromate of potash (20 parts), sulphuric acid (20 parts), and ferrous sulphate (10 parts). The ferrous sulphate here employed is oxidized by the chromic acid to a ferric salt, which serves as a carrier of oxygen to the aniline. This method of dyeing is easily carried out, and it gives a good black; but since much of the colouring matter is precipitated on the fibre superficially as well as in the bath itself, the colour has the defect of rubbing off. Another method is to impregnate the cotton with a solution containing aniline hydrochlorate (35 parts), neutralized with addition of a little aniline oil, sodium chlorate (10 parts), ammonium chloride (10 parts). Another mixture is 1·8 part aniline salt, 12 parts potassium ferrocyanide, water (200 parts), (3·5) potassium chlorate dissolved in water. After squeezing, the material is passed through a special oxidation chamber, the air of which is heated to about 50° C. and also supplied with moisture. This oxidizing or ageing is continuous, the material passing into the chamber at one end in a colourless condition, and after about 20 minutes passing out again with the black fully developed, a final treatment with hot chromic acid solution and soaping being necessary to complete the process. In this method, employing the first-mentioned solution, chlorate of copper is formed, and this being a very unstable compound, readily decomposes, and the aniline is oxidized by the liberated chlor-oxygen compounds. The presence in the mixture of a metallic salt is very important in aiding the development of the black, and for this purpose salts of vanadium, cerium, and copper have proved to be specially useful. The chemistry of aniline black is still incomplete, but it would appear that there are several oxidation products of aniline. The first product is so-called emeraldine, a dark green substance of the nature of a salt, which by treatment with alkali yields a dark blue base called azurine. The further oxidation of emeraldine yields nigraniline, also a dark green salt, but the free base of which has a violet black colour. The latter becomes greenish under the influence of acids, especially sulphuric acid, and explains the defect known as "greening" which is developed in ordinary aniline blacks during exposure to air. By a supplementary oxidation with chromic acid such a black is rendered ungreenable, the nigraniline being probably changed into the more stable chromate of nigraniline.

Catechu is a valuable brown dyestuff, obtained from various species of *Acacia*, *Areca*, and *Uncaria* growing in India. The wood, leaves, and fruit of these plants are extracted with boiling water; the decoction is then evaporated to dryness or to a pasty consistency. Catechu is largely used by the cotton dyer for the production of brown, drab, and similar colours. It is seldom employed for wool. Cotton is usually dyed by boiling it for about one hour in a decoction of catechu (100 per cent.) containing

copper sulphate (5 per cent.). After squeezing, the material is boiled for about fifteen minutes in a solution of bichromate of potash (¼ oz. per gal.), then washed and dried. By repeating the operations two or three times, deeper shades are obtained. During the boiling with catechu the cotton attracts the active principles catechin and catechu-tannic acid, but it thus acquires only a pale brown colour; in the bichromate of potash, however, these are oxidized to form insoluble japonic acid, which permeates the fibre, and a deep brown colour is thus developed. Catechu browns are fast to a variety of influences, *e.g.*, washing, alkalis, acids, &c., but less so to light. Catechu has been recently much employed, in conjunction with copper sulphate, for dyeing the so-called khaki-brown on woollen material for military clothing. On silk, catechu is much used for weighting purposes in dyeing black.

**Mineral Colours.**—These include Chrome Yellow, Iron Buff, Prussian Blue, and Manganese Brown.

CHROME YELLOW is only useful in cotton-dyeing as a self-colour, or for conversion into Chrome Orange, or, in conjunction with Indigo, for the production of fast green colours. The cotton is first impregnated with a solution of lead acetate or nitrate, squeezed, and then passed through a solution of sodium sulphate or lime water to fix the lead on the fibre, as sulphate or oxide of lead. The material is then passed through a solution of bichromate of potash. The colour is changed to a rich orange by a short, rapid passage through boiling milk of lime, and at once washing with water, a basic chromate of lead being thus produced. The colour is fast to light, but has the defect of being blackened by sulphuretted hydrogen.

IRON BUFF is produced by impregnating the cotton with a solution of ferrous sulphate, squeezing, passing into sodium hydrate or carbonate solution, and finally exposing to air, or passing through a dilute solution of bleaching powder. The colour obtained, which is virtually oxide of iron, or iron-rust, is fast to light, but readily removed by acids.

PRUSSIAN BLUE is applicable to wool, cotton, and silk, but since the introduction of coal-tar blues its employment has been very restricted. The colour is readily obtained on cotton by first dyeing an iron-buff, according to the method just described, and then passing the dyed cotton into an acidified solution of potassium ferrocyanide, when the blue is at once developed. A similar method is employed for silk. Wool is dyed by heating it in a solution containing potassium ferricyanide and sulphuric acid. The colour is developed gradually as the temperature rises; it may be rendered brighter by the addition of stannous chloride. On wool and silk, Prussian blue is very fast to light, but alkalis turn it brown (ferric oxide).

MANGANESE BROWN is applied in wool, silk, and cotton dyeing. The animal fibres are readily dyed by boiling with a solution of potassium permanganate, which, being at first absorbed by the fibre, is readily reduced to insoluble brown manganic hydrate. Imitation furs are dyed in this manner on wool-plush, the tips or other parts of the fibres being bleached by the application of sulphurous acid. Cotton is dyed by first impregnating it with a solution of manganous chloride, then dyeing and passing into a hot solution of caustic soda. There is thus precipitated on the fibre manganous hydrate, which by a short passage into a cold dilute solution of bleaching powder is oxidized and converted into the brown manganic hydrate. This manganese bronze or brown colour is very susceptible to, and readily bleached by, reducing agents; hence by the application of these, in conjunction with various dyestuffs, the calico-printer is able to produce a pleasing variety of so-called coloured discharge patterns.

**Theory of dyeing.**

With respect to the question of colour, we meet with two kinds of substances in nature, those which possess colour and those which do not. Why this difference? The physicist says the former are bodies which reflect all the coloured rays of the spectrum composing white light—if opaque, they appear white; if transparent, they are colourless. The latter are bodies which absorb some of the spectrum rays only, reflecting the remainder, and these together produce the impression of colour. A black substance is one which absorbs all the spectrum rays. The fundamental reason, however, of this difference of action on the part of substances towards light remains still unknown. All substances which possess colour are not necessarily dyestuffs, and the question may be again asked, Why? It is a remarkable circumstance that most of the dyestuffs at present employed occur among the so-called aromatic or benzene compounds derived from coal-tar, and a careful study of these has furnished a general explanation of the point in question, which briefly is, that the dyeing property of a substance depends upon its chemical constitution. Speaking generally, those colouring matters which have the simplest constitution are yellow, and as the molecular weight increases, their colour passes into orange, red, violet, and blue. In recent years chemists have begun to regard the constitution of nearly all dyestuffs as similar to that of Quinone, and some even believe that all coloured organic compounds have a quinonoid structure. According to O. N. Witt, a colourless hydrocarbon, *e.g.*, benzene, becomes coloured by the introduction of one or more special groups of atoms, which he terms the colour-bearing or *chromophorous groups*—*e.g.*, $NO_2$, $-N:N-$, &c. Benzene, for example, is colourless, whereas nitro-benzene and azo-benzene are yellow. Such compounds containing chromophorous groups are termed chromogens, because, although not dyestuffs themselves, they are capable of generating such by the further introduction of salt-forming atomic groups—*e.g.*, OH, $NH_2$. These Witt terms *auxochromous* groups. In this way the chromogen *tri-nitro-benzene* $C_6H_3(NO_2)_3$ becomes the dyestuff, *tri-nitro-phenol* (picric acid) $C_6H_2(NO_2)_3(OH)$, and the chromogen *azo-benzene* $C_6H_5 \cdot N:N \cdot C_6H_5$ is changed into the dyestuff *amido-azo-benzene* (Fast Yellow) $C_6H_5 \cdot N:N \cdot C_6H_4(NH_2)$. These two dyestuffs are typical of a large number which possess either an acid or a basic character according as they contain an hydroxyl (OH) or an amido ($NH_2$) group, and correspond to the Acid Colours and Basic Colours to which reference has already been made. Other important atomic groups which frequently occur, in addition to the above, are the carboxyl (COOH) and the sulphonic acid ($HSO_3$) groups; these either increase the solubility of the colouring matter or assist in causing it to be attracted by the fibre, &c. In many cases the free colour-acid or free colour-base has little colour, this being only developed in the salt. The free base rosaniline, for example, is colourless, whereas the salt magenta (rosaniline hydrochloride) has a deep crimson colour in solution. The free-acid Alizarine is orange, while its alumina-salt is bright red. It may be here stated that the scientific classification of colouring matters into Nitro-colours, Azo-colours, &c., already alluded to, is based on their chemical constitution, or the chromophorous groups they contain, whereas the classification according to their mode of application is dependent upon the character and arrangement of the auxochromous groups. The question of the mordant-dyeing property of certain colouring matters containing (OH) and (COOH) groups has already been explained under the head of *Artificial Mordant Colours*.

The peculiar property characteristic of dyestuffs, as distinguished from mere colouring matters, namely, that of being readily attracted by the textile fibres, notably the animal fibres, appears then to be due to their more or less marked acid or basic character. Intimately connected with this is the fact that these fibres also exhibit partly basic and partly acid characters, due to the presence of carboxyl and amido groups. The behaviour of magenta is typical of the Basic Colours. As already indicated, rosaniline, the base of magenta, is colourless, and only becomes coloured by its union with an acid, and yet wool and silk can be as readily dyed with the colourless rosaniline (base) as with the magenta (salt). The explanation is that the base rosaniline has united with the fibre, which here plays the part of an acid, to form a coloured salt. It has also been proved that in dyeing the animal fibres with magenta (rosaniline hydrochloride), the fibre unites with the rosaniline only, and liberates the hydrochloric acid. Further, in dyeing cotton with magenta it is necessary to prepare the cotton previously with the mordant tannic acid, with which the base rosaniline unites to form an insoluble salt.

In dyeing wool it is the fibre itself which acts as the mordant. In the case of the Acid Colours the explanation is similar. In many of these the free colour-acid has quite a different colour (purple) from that of the alkali-salt (yellow), and yet on dyeing wool or silk with the free colour-acid, the fibre exhibits the colour of the alkali-salt and not of the colour-acid. In this case the fibre evidently plays the part of a base. Another fact in favour of the view that the union between fibre and colouring matter is of a chemical nature, is that by altering the chemical constitution of the fibre its dyeing properties are also altered; oxycellulose and nitrocellulose, for example, have a greater attraction for Basic Colours than cellulose. Such facts and considerations as these have helped to establish the view that in the case of dyeing animal fibres with many colouring matters the operation is a *chemical* process, and not merely a mechanical absorption of the dyestuff. A similar explanation does not suffice, however, in the case of dyeing cotton with the Direct Colours; also in some cases of dyeing wool and silk—*e.g.*, with Orchil. These are attracted by cotton from their solutions as alkali salts, apparently without decomposition. The affinity existing between the fibre and colouring matter is somewhat feeble, for the latter can readily be removed from the dyed fibre by merely boiling with water. The depth of colour obtained in dyeing varies with the concentration of the colour solution, or with the amount of some neutral salt—*e.g.*, sodium chloride, added as an assistant to the dyebath; moreover, the dyebath is never completely exhausted. The colouring matter is submitted to the action of two forces, the solvent power of the water and the affinity of the fibre, and divides itself between the fibre and the water. After dyeing for some time, a state of equilibrium is attained in which the colouring matter is divided between the fibre and the water in a given ratio, and prolonged dyeing does not intensify the dyed colour. An interesting fact bearing on this question is that some basic colouring matters are capable of dyeing—amorphous sulphur, gelatin, silicic acid, infusorial earth, &c.

These and other similar facts have led to the adoption by various investigators of the view that in some cases the fibres exert a purely physical attraction towards colouring matters, and that the latter are held in an unchanged state by the fibre. The phenomenon is regarded as one of purely mechanical surface-attraction, very similar to that exercised by animal charcoal when employed in decolorizing a solution of some colouring matter. Some consider such direct dyeing as mere diffusion of the colouring matter into the fibre, and others that the colouring matter is in a state of "solid solution" in the fibre, similar to the solution of a metallic oxide in coloured glass. According to this latter view, the cause of the dyeing of textile fibres is similar to the attraction or solvent action exerted by ether when it withdraws colouring matter from an aqueous solution by agitation.

In the case of colours which are dyed on mordants, the question is merely transferred to the nature of the attraction which exists between the fibre and the mordant, for it has been conclusively established that the union between the colouring matter and the mordant is essentially chemical in character.

From our present knowledge it will be seen that we are unable to give a final answer to the question of whether the dyeing process is to be regarded as a chemical or a mechanical process. There are arguments and facts which favour both views; but in the case of wool and silk dyeing, the prevailing opinion in most cases is in favour of the chemical theory, whereas in cotton-dyeing the mechanical theory is widely accepted. Probably no single theory can explain satisfactorily the fundamental cause of attraction in all cases of dyeing, and further investigation is needed to answer fully this very difficult and abstruse question.

**Conclusion.**

The poisonous nature or otherwise of the coal-tar dyes has been frequently discussed, and the popular opinion, no doubt dating from the time when magenta and its derivatives were contaminated with arsenic, seems to be that they are for the most part really poisonous, and ought to be avoided for colouring materials worn next the skin, for articles of food, &c. It is satisfactory to know that most of the colours are not poisonous, but some few are—namely, Picric acid, Victoria Orange, Aurantia, Coralline, Metanil Yellow, Orange II., and Safranine. Many coal-tar colours have, indeed, been recommended as antiseptics or as medicinal remedies, *e.g.*, Methyl Violet, Auramine, and Methylene Blue, because of their special physiological action. In histology and bacteriology many coal-tar colours have rendered excellent service in staining microscopic preparations, and have enabled the investigator to detect differences of structure, &c., previously unsuspected. In photography many of the more fugitive colouring matters, *e.g.*, Cyanine, Eosine, Quinoline Red, &c., are employed in the manufacture of ortho-chromatic plates, by means of which the colours of natural objects can be photographed in the same degrees of light and shade as they appear to the eye—blue, for example, appearing a darker grey, yellow a lighter grey, in the printed photograph.

Since the year 1856, in which the first coal-tar colour, mauve, was discovered, the art of dyeing has made enormous advances, mainly in consequence of the continued introduction of coal-tar colours having the most varied properties and suitable for nearly every requirement. The old idea that the vegetable dyestuffs are superior in fastness to light is gradually being given up, and, if one may judge from the past, it seems evident that in the future there will come a time when all our dyestuffs will be prepared by artificial means.

**Dynamics, Analytical.**—The fundamental principles of Dynamics, and their application to special problems, are explained under MECHANICS (*Ency. Brit.* vol. xv.), where brief indications are also given of the more general methods of investigating the properties of a dynamical system, independently of the accidents of its particular constitution, which were inaugurated by Lagrange. These methods, in addition to the unity and breadth which they have introduced into the treatment of pure dynamics, have a peculiar interest in relation to modern physical speculation, which finds itself confronted in various directions with the problem of explaining on dynamical principles the properties of systems whose ultimate mechanism can at present only be vaguely conjectured. This article is devoted to an outline of such portions of general dynamical theory as seem to be most important from this latter point of view.

*General Equations of Impulsive Motion.*

§ 1. The systems contemplated by Lagrange are composed of discrete particles, or of rigid bodies, in finite number, connected (it may be) in various ways by invariable geometrical relations, the fundamental postulate being that the position of every particle of the system at any time can be completely specified by means of the instantaneous values of a finite number of independent variables $q_1, q_2, \dots q_n$, each of which admits of continuous variation over a certain range, so that if $x, y, z$ be the Cartesian co-ordinates of any one particle, we have for example

$$x=f(q_1, q_2, \dots q_n), \quad y=\&c., \quad z=\&c., \qquad (1)$$

where the functions $f$ differ (of course) from particle to particle. In modern language, the variables $q_1, q_2, \dots q_n$ are *generalized co-ordinates* serving to specify the *configuration* of the system; their derivatives with respect to the time are denoted by $\dot{q}_1, \dot{q}_2, \dots \dot{q}_n$, and are called the *generalized components of velocity*. The continuous sequence of configurations assumed by the system in any actual or imagined motion (subject to the given connexions) is called the *path*.

For the purposes of a connected outline of the whole subject it is convenient to deviate somewhat from the historical order of development, and to begin with the consideration of *impulsive* motion. Whatever the actual motion of the system at any instant, we may conceive it to be generated instantaneously from rest by the application of proper impulses. On this view we have, if $x, y, z$ be the rectangular co-ordinates of any particle $m$,

**Impulsive motion.**

$$m\dot{x}=X', \quad m\dot{y}=Y', \quad m\dot{z}=Z', \qquad (2)$$

where $X', Y', Z'$ are the components of the impulse on $m$. Now let $\delta x, \delta y, \delta z$ be any infinitesimal variations of $x, y, z$ which are consistent with the connexions of the system, and let us form the equation

$$\Sigma m(\dot{x}\delta x+\dot{y}\delta y+\dot{z}\delta z)=\Sigma(X'\delta x+Y'\delta y+Z'\delta z), \qquad (3)$$

where the sign $\Sigma$ indicates (as throughout this article) a summation extending over all the particles of the system. To transform (3) into an equation involving the variations $\delta q_1, \delta q_2, \dots$ of the generalized co-ordinates, we have

$$\dot{x}=\frac{\partial x}{\partial q_1}\dot{q}_1+\frac{\partial x}{\partial q_2}\dot{q}_2+\dots, \ \&c., \&c., \qquad (4)$$

$$\delta x=\frac{\partial x}{\partial q_1}\delta q_1+\frac{\partial x}{\partial q_2}\delta q_2+\dots, \ \&c., \&c., \qquad (5)$$

and therefore

$$\Sigma m(\dot{x}\delta x+\dot{y}\delta y+\dot{z}\delta z)=(A_{11}\dot{q}_1+A_{12}\dot{q}_2+\dots)\delta q_1 + (A_{21}\dot{q}_1+A_{22}\dot{q}_2+\dots)\delta q_2+\dots, \qquad (6)$$

where

$$\left.\begin{aligned} A_{rr}&=\Sigma m\left\{\left(\frac{\partial x}{\partial q_r}\right)^2+\left(\frac{\partial y}{\partial q_r}\right)^2+\left(\frac{\partial z}{\partial q_r}\right)^2\right\}, \\ A_{rs}&=\Sigma m\left\{\frac{\partial x}{\partial q_r}\frac{\partial x}{\partial q_s}+\frac{\partial y}{\partial q_r}\frac{\partial y}{\partial q_s}+\frac{\partial z}{\partial q_r}\frac{\partial z}{\partial q_s}\right\}=A_{sr}. \end{aligned}\right\} \qquad (7)$$

If we form the expression for the kinetic energy T of the system, we find

$$2T=\Sigma m(\dot{x}^2+\dot{y}^2+\dot{z}^2)=A_{11}\dot{q}_1^2+A_{22}\dot{q}_2^2+\dots+2A_{12}\dot{q}_1\dot{q}_2+\dots \qquad (8)$$

The coefficients $A_{11}, A_{22}, \dots A_{12}, \dots$ are by an obvious analogy called the *coefficients of inertia* of the system; they are in general functions of the co-ordinates $q_1, q_2, \dots$. The equation (6) may now be written

$$\Sigma m(\dot{x}\delta x+\dot{y}\delta y+\dot{z}\delta z)=\frac{\partial T}{\partial \dot{q}_1}\delta q_1+\frac{\partial T}{\partial \dot{q}_2}\delta q_2+\dots. \qquad (9)$$

This may be regarded as the cardinal formula in Lagrange's method. For the right-hand side of (3) we may write

$$\Sigma(X'\delta x+Y'\delta y+Z'\delta z)=Q'_1\delta q_1+Q'_2\delta q_2+\dots, \qquad (10)$$

where

$$Q'_r=\Sigma\left(X'\frac{\partial x}{\partial q_r}+Y'\frac{\partial y}{\partial q_r}+Z'\frac{\partial z}{\partial q_r}\right). \qquad (11)$$

The quantities $Q_1, Q_2, \dots$ are called the *generalized components of impulse*. Comparing (9) and (10), we have, since the variations $\delta q_1, \delta q_2, \dots$ are independent,

$$\frac{\partial T}{\partial \dot{q}_1}=Q'_1, \quad \frac{\partial T}{\partial \dot{q}_2}=Q'_2, \ \dots \qquad (12)$$

These are the general equations of impulsive motion.

It is now usual to write

$$p_r=\frac{\partial T}{\partial \dot{q}_r}. \qquad (13)$$

The quantities $p_1, p_2, \dots$ represent the effects of the several component impulses on the system, and are therefore called the *generalized components of momentum.* In terms of them we have

$$\Sigma m(\dot{x}\delta x+\dot{y}\delta y+\dot{z}\delta z)=p_1\delta q_1+p_2\delta q_2+\dots \qquad (14)$$

Also, since T is a homogeneous quadratic function of the velocities $\dot{q}_1, \dot{q}_2, \dots$,

$$2T=p_1\dot{q}_1+p_2\dot{q}_2+\dots. \qquad (15)$$

This follows independently from (14), assuming the special variations $\delta x=\dot{x}dt$, &c., and therefore $\delta q_1=\dot{q}_1 dt$, $\delta q_2=\dot{q}_2 dt, \dots$.

Again, if the values of the velocities and the momenta in any other motion of the system through the same configuration be distinguished by accents, we have the identity

**Reciprocal Theorems.**

$$p_1\dot{q}'_1+p_2\dot{q}'_2+\dots=p'_1\dot{q}_1+p'_2\dot{q}_2+\dots, \qquad (16)$$

each side being equal to the symmetrical expression

$$A_{11}\dot{q}_1\dot{q}'_1+A_{22}\dot{q}_2\dot{q}'_2+\dots+A_{12}(\dot{q}_1\dot{q}'_2+\dot{q}'_1\dot{q}_2)+\dots. \qquad (17)$$

The theorem (16) leads to some important reciprocal relations. Thus, let us suppose that the momenta $p_1, p_2, \dots$ all vanish with the exception of $p_1$, and similarly that the momenta $p'_1, p'_2, \dots$ all vanish except $p'_2$. We have then $p_1\dot{q}'_1=p'_2\dot{q}_2$, or

$$\dot{q}_2 : p_1=\dot{q}'_1 : p'_2. \qquad (18)$$

The interpretation is simplest when the co-ordinates $q_1, q_2$ are both of the same kind, *e.g.*, both lines, or both angles. We may then conveniently put $p_1=p'_2$, and assert that the velocity of the first type due to an impulse of the second type is equal to the velocity of the second type due to an equal impulse of the first type. As an example, suppose we have a chain of straight links hinged each to the next, extended in a straight line, and free to move. A blow at right angles to the chain, at any point P, will produce a certain velocity at any other point Q; the theorem asserts that an equal velocity will be produced at P by an equal blow at Q. Again, an impulsive couple acting on any link A will produce a certain angular velocity in any other link B; an equal couple applied to B will produce an equal angular velocity in A. Also if an impulse F applied at P produce an angular velocity $\omega$ in a link A, a couple F$a$ applied to A will produce a linear velocity $\omega a$ at P. Historically, we may note that reciprocal relations in

dynamics were first recognized by Helmholtz in the domain of acoustics; their use has been greatly extended by Lord Rayleigh.

The equations (13) determine the momenta $p_1, p_2, \ldots$ as linear functions of the velocities $\dot{q}_1, \dot{q}_2, \ldots$. Solving these, we can express $\dot{q}_1, \dot{q}_2, \ldots$ as linear functions of $p_1, p_2, \ldots$. The resulting equations give us the velocities produced by any given system of impulses. Further, by substitution in (8), we can express the kinetic energy as a homogeneous quadratic function of the momenta $p_1, p_2, \ldots$. The kinetic energy, *as so expressed*, will be denoted by $T'$; thus

***Velocities in terms of momenta.***

$$2T' = A'_{11}p_1^2 + A'_{22}p_2^2 + \ldots + 2A'_{12}p_1p_2 + \ldots \quad . \quad (19)$$

where $A'_{11}, A'_{22}, \ldots A'_{12}, \ldots$ are certain coefficients depending on the configuration. They have been called by Maxwell the *coefficients of mobility* of the system. When the form (19) is given, the values of the velocities in terms of the momenta can be expressed in a remarkable form due to Hamilton. The formula (15) may be written

$$p_1\dot{q}_1 + p_2\dot{q}_2 + \ldots = T + T', \quad . \quad . \quad . \quad (20)$$

where T is supposed expressed as in (8), and $T'$ as in (19). Hence if, for the moment, we denote by $\delta$ a variation affecting the velocities, and therefore the momenta, but not the configuration, we have

$$p_1\delta\dot{q}_1 + \dot{q}_1\delta p + p_2\delta\dot{q}_2 + \dot{q}_2\delta p_2 + \ldots = \delta T + \delta T'$$

$$= \frac{\partial T}{\partial \dot{q}_1}\delta\dot{q}_1 + \frac{\partial T}{\partial \dot{q}_2}\delta\dot{q}_2 + \ldots + \frac{\partial T'}{\partial p_1}\delta p_1 + \frac{\partial T'}{\partial p_2}\delta p_2 + \ldots \quad . \quad (21)$$

In virtue of (13) this reduces to

$$\dot{q}_1\delta p_1 + \dot{q}_2\delta p_2 + \ldots = \frac{\partial T'}{\partial p_1}\delta p_1 + \frac{\partial T'}{\partial p_2}\delta p_2 + \ldots \quad . \quad (22)$$

Since $\delta p_1, \delta p_2, \ldots$ may be taken to be independent, we infer that

$$\dot{q}_1 = \frac{\partial T'}{\partial p_1}, \quad \dot{q}_2 = \frac{\partial T'}{\partial p_2}, \quad \ldots \quad . \quad (23)$$

In the very remarkable exposition of the matter given by Maxwell in his *Electricity and Magnetism*, the Hamiltonian expressions (23) for the velocities in terms of the impulses are obtained directly from first principles, and the formulæ (13) are then deduced by an inversion of the above argument.

An important modification of the above process has been introduced in recent times by Routh and Thomson and Tait. Instead of expressing the kinetic energy in terms of the velocities alone, or in terms of the momenta alone, we may express it in terms of the velocities corresponding to some of the co-ordinates, say $q_1, q_2, \ldots q_m$, and of the momenta corresponding to the remaining co-ordinates, which (for the sake of distinction) we may denote by $\chi, \chi', \chi'', \ldots$. Thus, T being expressed as a homogeneous quadratic function of $\dot{q}_1, \dot{q}_2, \ldots \dot{q}_m, \dot{\chi}, \dot{\chi}', \dot{\chi}'', \ldots$, the momenta corresponding to the co-ordinates $\chi, \chi', \chi'', \ldots$ may be written

***Routh's modification.***

$$\kappa = \frac{\partial T}{\partial \dot{\chi}}, \quad \kappa' = \frac{\partial T}{\partial \dot{\chi}'}, \quad \kappa'' = \frac{\partial T}{\partial \dot{\chi}''}, \quad \ldots \quad . \quad (24)$$

These equations, when written out in full, determine $\dot{\chi}, \dot{\chi}', \dot{\chi}'', \ldots$ as linear functions of $\dot{q}_1, \dot{q}_2, \ldots \dot{q}_m, \kappa, \kappa', \kappa'', \ldots$. We now consider the function

$$\Theta = T - \kappa\dot{\chi} - \kappa'\dot{\chi}' - \kappa''\dot{\chi}'' - \ldots, \quad . \quad . \quad (25)$$

supposed expressed, by means of the above relations, in terms of $\dot{q}_1, \dot{q}_2, \ldots \dot{q}_m, \kappa, \kappa', \kappa'', \ldots$. Performing the operation $\delta$ on both sides of (25), we have

$$\frac{\partial\Theta}{\partial \dot{q}_1}\delta\dot{q}_1 + \ldots + \frac{\partial\Theta}{\partial\kappa}\delta\kappa + \ldots = \frac{\partial T}{\partial \dot{q}_1}\delta\dot{q}_1 + \ldots + \frac{\partial T}{\partial\dot{\chi}}\delta\dot{\chi} + \ldots$$
$$- \kappa\delta\dot{\chi} - \dot{\chi}\delta\kappa - \ldots, \quad . \quad . \quad (26)$$

where, for brevity, only one term of each type has been exhibited. Omitting the terms which cancel in virtue of (24), we have

$$\frac{\partial\Theta}{\partial \dot{q}_1}\delta\dot{q}_1 + \ldots + \frac{\partial\Theta}{\partial\kappa}\delta\kappa + \ldots = \frac{\partial T}{\partial \dot{q}_1}\delta\dot{q}_1 + \ldots - \dot{\chi}\delta\kappa - \ldots \quad . \quad (27)$$

Since the variations $\delta q_1, \delta q_2, \ldots \delta q_m, \delta\kappa, \delta\kappa', \delta\kappa'', \ldots$ may be taken to be independent, we have

$$p_1 = \frac{\partial T}{\partial \dot{q}_1} = \frac{\partial\Theta}{\partial \dot{q}_1}, \quad p_2 = \frac{\partial T}{\partial \dot{q}_2} = \frac{\partial\Theta}{\partial \dot{q}_2}, \quad \ldots \quad . \quad (28)$$

and

$$\dot{\chi} = -\frac{\partial\Theta}{\partial\kappa}, \quad \dot{\chi}' = -\frac{\partial\Theta}{\partial\kappa'}, \quad \dot{\chi}'' = -\frac{\partial\Theta}{\partial\kappa''} \quad \ldots \quad . \quad (29)$$

An important property of the present transformation is that, when expressed in terms of the new variables, the kinetic energy is the sum of two homogeneous quadratic functions, thus

$$T = \mathfrak{T} + K, \quad . \quad . \quad . \quad . \quad (30)$$

where $\mathfrak{T}$ involves the velocities $\dot{q}_1, \dot{q}_2, \ldots \dot{q}_m$ alone, and K the momenta $\kappa, \kappa', \kappa'', \ldots$ alone. For in virtue of (29) we have, from (25),

$$T = \Theta - \left(\kappa\frac{\partial\Theta}{\partial\kappa} + \kappa'\frac{\partial\Theta}{\partial\kappa'} + \kappa''\frac{\partial\Theta}{\partial\kappa''} + \ldots\right), \quad . \quad . \quad (31)$$

and it is evident that the terms in $\Theta$ which are bilinear in respect of the two sets of variables $\dot{q}_1, \dot{q}_2, \ldots \dot{q}_m$ and $\kappa, \kappa', \kappa'', \ldots$ will disappear from the right-hand side.

It may be noted that the formula (30) gives immediate proof of two important theorems due to Bertrand and to Lord Kelvin respectively. Let us suppose, in the first place, that the system is started by given impulses of certain types, but is otherwise free. Bertrand's theorem is to the effect that the kinetic energy is *greater* than if by impulses of the remaining types the system were constrained to take any other course. We may suppose the co-ordinates to be so chosen that the constraint is expressed by the vanishing of the velocities $\dot{q}_1, \dot{q}_2, \ldots \dot{q}_m$, whilst the given impulses are $\kappa, \kappa', \kappa'', \ldots$. Hence the energy in the actual motion is greater than in the constrained motion by the amount $\mathfrak{T}$.

***Maximum and minimum energy.***

Again, suppose that the system is started with prescribed velocity components $\dot{q}_1, \dot{q}_2, \ldots \dot{q}_m$, by means of proper impulses of the corresponding types, but is otherwise free, so that in the motion actually generated we have $\kappa = 0, \kappa' = 0, \kappa'' = 0, \ldots$ and therefore $K = 0$. The kinetic energy is therefore *less* than in any other motion consistent with the prescribed velocity-conditions by the value which K assumes when $\kappa, \kappa', \kappa'', \ldots$ represent the impulses due to the constraints.

Simple illustrations of these theorems are afforded by the chain of straight links already employed. Thus if a point of the chain be held fixed, or if one or more of the joints be made rigid, the energy generated by any given impulses is less than if the chain had possessed its former freedom.

*Continuous Motion of a System.*

§ 2. We may proceed to the continuous motion of a system. The equations of motion of any particle of the system are of the form

$$m\ddot{x} = X, \quad m\ddot{y} = Y, \quad m\ddot{z} = Z. \quad . \quad . \quad (1)$$

Now let $x + \delta x$, $y + \delta y$, $z + \delta z$ be the co-ordinates of $m$ in any arbitrary motion of the system differing infinitely little from the actual motion, and let us form the equation

***Lagrange's equations.***

$$\Sigma m(\ddot{x}\delta x + \ddot{y}\delta y + \ddot{z}\delta z) = \Sigma(X\delta x + Y\delta y + Z\delta z). \quad . \quad (2)$$

Lagrange's investigation consists in the transformation of (2) into an equation involving the independent variations $\delta q_1, \delta q_2, \ldots \delta q_n$.

It is important to notice that the symbols $\delta$ and $d/dt$ are commutative, since

$$\delta\dot{x} = \frac{d}{dt}(x + \delta x) - \frac{dx}{dt} = \frac{d}{dt}\delta x, \text{ \&c.} \quad . \quad . \quad (3)$$

Hence

$$\Sigma m(\ddot{x}\delta x + \ddot{y}\delta y + \ddot{z}dz) = \frac{d}{dt}\Sigma m(\dot{x}\delta x + \dot{y}\delta y + \dot{z}\delta z)$$
$$- \Sigma m(\dot{x}\delta\dot{x} + \dot{y}\delta\dot{y} + \dot{z}\delta\dot{z})$$
$$= \frac{d}{dt}(p_1\delta q_1 + p_2\delta q_2 + \ldots) - \delta T, \quad . \quad . \quad . \quad (4)$$

by § 1 (14). The last member may be written

$$\dot{p}_1\delta q_1 + p_1\delta\dot{q}_1 + \dot{p}_2\delta q_2 + p_2\delta\dot{q}_2 + \ldots$$
$$- \frac{\partial T}{\partial \dot{q}_1}\delta\dot{q}_1 - \frac{\partial T}{\partial q}\delta q_1 - \frac{\partial T}{\partial \dot{q}_2}\delta\dot{q}_2 - \frac{\partial T}{\partial q_2}\delta q_2 - \ldots \quad . \quad (5)$$

Hence, omitting the terms which cancel in virtue of § 1 (13), we find

$$\Sigma m(\ddot{x}\delta x + \ddot{y}\delta y + \ddot{z}\delta z) = \left(\dot{p}_1 - \frac{\partial T}{\partial q_1}\right)\delta q_1 + \left(\dot{p}_2 - \frac{\partial T}{\partial q_2}\right)\delta q_2 + \ldots \quad . \quad (6)$$

For the right-hand side of (2) we have

$$\Sigma(X\delta x + Y\delta y + Z\delta z) = Q_1\delta q_1 + Q_2\delta q_2 + \ldots, \quad . \quad (7)$$

$$Q_r = \Sigma\left(X\frac{\partial x}{\partial q_r} + Y\frac{\partial y}{\partial q_r} + Z\frac{\partial z}{\partial q_r}\right). \quad . \quad . \quad (8)$$

The quantities $Q_1, Q_2, \ldots$ are called the *generalized components of force* acting on the system.

Comparing (6) and (7) we find

$$\dot{p}_1 - \frac{\partial T}{\partial q_1} = Q_1, \quad \dot{p}_2 - \frac{\partial T}{\partial q_2} = Q_2, \quad \ldots, \quad . \quad . \quad (9)$$

or, restoring the values of $p_1, p_2, \ldots$,

$$\frac{d}{dt}\left(\frac{\partial T}{\partial \dot{q}_1}\right) - \frac{\partial T}{\partial q_1} = Q_1, \quad \frac{d}{dt}\left(\frac{\partial T}{\partial \dot{q}_2}\right) - \frac{\partial T}{\partial q_2} = Q_2, \quad \ldots \quad . \quad (10)$$

These are Lagrange's general equations of motion. Their number is of course equal to that of the co-ordinates $q_1, q_2, \ldots$ to be determined.

Analytically, the above proof is that given by Lagrange, but the terminology employed is of much more recent date, having been first introduced by Thomson and Tait; it has greatly promoted the physical application of the subject. Another proof of the equations (10), by direct transformation of co-ordinates, has

been given by Hamilton and other writers, but the variational method of Lagrange is that which stands in closest relation to the subsequent developments of the subject. The chapter of Maxwell, already referred to, is a most instructive commentary on the subject from the physical point of view, although the proof there attempted of the equations (10) is fallacious.

In a "conservative system" the work which would have to be done by extraneous forces to bring the system from rest in some standard configuration to rest in the configuration $(q_1, q_2, \dots q_n)$ is independent of the path, and may therefore be regarded as a definite function of $q_1, q_2, \dots q_n$. Denoting this function (the *potential energy*) by V, we have, if there be no extraneous force on the system,

$$\Sigma(X\delta x + Y\delta y + Z\delta z) = -\delta V, \qquad (11)$$

and therefore

$$Q_1 = -\frac{\partial V}{\partial q_1},\ \ Q_2 = -\frac{\partial V}{\partial q_2},\ \dots \qquad (12)$$

Hence the typical Lagrange's equation may be now written in the form

$$\frac{d}{dt}\left(\frac{\partial T}{\partial \dot q_r}\right) - \frac{\partial T}{\partial q_r} = -\frac{\partial V}{\partial q_r}, \qquad (13)$$

or, again,

$$\dot p_r = -\frac{\partial}{\partial q_r}(V - T). \qquad (14)$$

It has been proposed by Helmholtz to give the name *kinetic potential* to the combination V − T.

To calculate the rate at which the kinetic energy varies in the actual motion we have

$$2\frac{dT}{dt} = \frac{d}{dt}(p_1\dot q_1 + p_2\dot q_2 + \dots) = \dot p_1\dot q_1 + p_1\ddot q_1 + \dot p_2\dot q_2 + p_2\ddot q_2 + \dots$$
$$= \left(\frac{\partial T}{\partial q_1} + Q_1\right)\dot q_1 + \left(\frac{\partial T}{\partial q_2} + Q_2\right)\dot q_2 + \dots + \frac{\partial T}{\partial \dot q_1}\ddot q_1 + \frac{\partial T}{\partial \dot q_2}\ddot q_2 + \dots, \qquad (15)$$

by (9). This may be written

$$2\frac{dT}{dt} = \frac{dT}{dt} + Q_1\dot q_1 + Q_2\dot q_2 + \dots \qquad (16)$$

or

$$\frac{dT}{dt} = Q_1\dot q_1 + Q_2\dot q_2 + \dots \qquad (17)$$

This expresses that the kinetic energy is increasing at a rate equal to that at which work is being done by the forces. In the case of a conservative system free from extraneous force, we have, substituting the values of $Q_1, Q_2, \dots$ from (12),

$$\frac{d}{dt}(T + V) = 0 \quad \text{or} \quad T + V = \text{const.}, \qquad (18)$$

which is the equation of energy.

A classical example of the application of Lagrange's equations is to the motion of a top. A rigid body, symmetrical about an axis, is supposed free to turn about a fixed point O in this axis, at a distance $h$ (say) from the centre of mass. Let $\theta$ be the angle which OG makes with the vertical OZ, $\psi$ the azimuth of the plane ZOG relative to a fixed vertical plane ZOX, and $\phi$ the angle which a meridian plane fixed in the solid makes with the plane ZOG, the notation being in fact that of MECHANICS, § 81. Denoting the principal moments of inertia by A, A, C, we have

***Application to the top.***

$$2T = A(\omega_1^2 + \omega_2^2) + C\omega_3^2$$
$$= A(\dot\theta^2 + \sin^2\theta\dot\psi^2) + C(\dot\phi + \dot\psi\cos\theta)^2 \dots \qquad (19)$$

If $\lambda$, $\mu$, $\nu$ be the corresponding components of momentum, we have

$$\left.\begin{aligned} \lambda = \frac{\partial T}{\partial \dot\theta} = A\dot\theta \quad \mu = \frac{\partial T}{\partial \dot\psi} = A\sin^2\theta\dot\psi + C(\dot\phi + \dot\psi\cos\theta)\cos\theta,\\ \nu = \frac{\partial T}{\partial \dot\phi} = C(\dot\phi + \dot\psi\cos\theta)\dots \end{aligned}\right\} (20)$$

The geometrical meaning of these quantities is recognized at once from the expression for the virtual moment of the impulses,

$$\lambda\delta\theta + \mu\delta\psi + \nu\delta\phi, \qquad (21)$$

viz., $\lambda$ is the angular momentum about an axis normal to the plane of $\theta$, $\mu$ is the angular momentum about the vertical, and $\nu$ that about the axis OG. If M be the total mass, the potential energy is

$$V = Mgh\cos\theta. \qquad (22)$$

Hence the equations (10) become

$$\left.\begin{aligned} &A\ddot\theta - A\sin\theta\cos\theta\dot\psi^2 + C(\dot\phi + \dot\psi\cos\theta)\dot\psi\sin\theta = Mgh\sin\theta,\\ &\frac{d}{dt}\{A\sin^2\theta\dot\psi + C(\dot\phi + \dot\psi\cos\theta)\cos\theta\} = 0,\\ &\frac{d}{dt}C(\dot\phi + \dot\psi\cos\theta) = 0, \end{aligned}\right\} \qquad (23)$$

of which the last two express the constancy of the momenta $\mu$, $\nu$. Hence

$$\left.\begin{aligned} A\ddot\theta - A\sin\theta\cos\theta\dot\psi^2 + \nu\sin\theta\dot\psi = Mgh\sin\theta,\\ A\sin^2\theta\dot\psi + \nu\cos\theta = \mu, \end{aligned}\right\} \qquad (24)$$

or, eliminating $\dot\psi$,

$$A\ddot\theta - \frac{(\mu - \nu\cos\theta)(\mu\cos\theta - \nu)}{A\sin^3\theta} = Mgh\sin\theta. \qquad (25)$$

An immediate application of (24) is to find the condition for a steady precessional motion, *i.e.*, one in which the axis of the top describes a right circular cone about the vertical. Putting $\ddot\theta = 0$, $\theta = \alpha$, in (24), we obtain

$$A\cos\alpha\dot\psi^2 - \nu\dot\psi + Mgh = 0. \qquad (26)$$

For given values of $\nu$ and $\alpha$ we have two possible values of $\dot\psi$, provided $\nu$ exceed a certain limit. With very rapid rotation, or more precisely, with $\nu$ large in comparison with $\sqrt{(4AMgh\cos\alpha)}$, one value of $\dot\psi$ is small and the other large, viz., the two values are $Mgh/\nu$ and $\nu/A\cos\alpha$, approximately. To find the small oscillation about the steady motion we put $\theta = \alpha + \chi$ in (25), and neglect terms of the second order in $\chi$. The usual method leads to an equation of the type

***Small oscillations.***

$$\ddot\chi + p^2\chi = 0, \qquad (27)$$

where

$$p^2 = \frac{(\mu - \nu\cos\alpha)^2 + 2(\mu - \nu\cos\alpha)(\mu\cos\alpha - \nu)\cos\alpha + (\mu\cos\alpha - \nu)^2}{A^2\sin^4\alpha} \qquad (28)$$

When $\nu$ is large we find that for the slow precession $p = \nu/A$, whilst for the rapid precession $p = \nu/A\cos\alpha = \dot\psi$, approximately. Further, on examining the small variation in $\dot\psi$, it appears that in a slightly disturbed *slow* precession the motion of any point of the axis consists of a rapid circular motion superposed on the slow precession, so that the resultant path has a trochoidal character. This is a type of motion commonly observed in a top spun in the ordinary way, although the successive undulations of the trochoids may be too small to be directly observed. In a slightly disturbed *rapid* precession the added vibration is elliptic-harmonic, with a period equal to that of the precession itself. The ratio of the axes of the ellipse is sec $\alpha$, the major axis being in the plane of $\theta$. The result is that the axis describes a circular cone about a fixed line making a small angle with the vertical. Another view of the matter is appropriate when we study the small oscillations about the vertical position $\alpha = 0$. The motion of any point of the axis may then be described as an elliptic-harmonic motion superposed on a uniform rotation with angular velocity $\nu/2A$ about the vertical OZ. The period of revolution in the ellipse is $2\pi/p$, where

$$p^2 = \frac{\nu^2 - 4AMgh}{4A^2} \qquad (29)$$

This would indicate that the upright position of a top (with the centre of gravity above the pivot) is stable if, and only if, $\nu^2 > 4AMgh$. See, however, § 6.

### *Constrained Systems.*

§ 3. It has so far been assumed that the geometrical relations, if any, which exist between the various parts of the system are of the type § 1 (1), and so do not contain $t$ explicitly. The extension of Lagrange's equations to the case of "varying relations" of the type

***Case of varying relations.***

$$x = f(t, q_1, q_2, \dots q_n),\ y = \&c.,\ z = \&c. \qquad (1)$$

was made by Vieille. We now have

$$\dot x = \frac{\partial x}{\partial t} + \frac{\partial x}{\partial q_1}\dot q_1 + \frac{\partial x}{\partial q_2}\dot q_2 + \dots,\ \&c.,\ \&c., \qquad (2)$$

$$\delta x = \frac{\partial x}{\partial q_1}\delta q_1 + \frac{\partial x}{\partial q_2}\delta q_2 + \dots,\ \&c.,\ \&c., \qquad (3)$$

so that the expression § 1 (8) for the kinetic energy is to be replaced by

$$2T = a_0 + 2a_1\dot q_1 + 2a_2\dot q_2 + \dots + A_{11}\dot q_1^2 + A_{22}\dot q_2^2 + \dots + A_{12}\dot q_1\dot q_2 + \dots, \qquad (4)$$

where

$$\left.\begin{aligned} a_0 = \Sigma m\left\{\left(\frac{\partial x}{\partial t}\right)^2 + \left(\frac{\partial y}{\partial t}\right)^2 + \left(\frac{\partial z}{\partial t}\right)^2\right\},\\ a_r = \Sigma m\left\{\frac{\partial x}{\partial t}\frac{\partial x}{\partial q_r} + \frac{\partial y}{\partial t}\frac{\partial y}{\partial q_r} + \frac{\partial z}{\partial t}\frac{\partial z}{\partial q_r}\right\}, \end{aligned}\right\} \qquad (5)$$

and the forms of $A_{rr}$, $A_{rs}$ are as given by § 1 (7). It is to be remembered that the coefficients $a_0, a_1, a_2, \dots A_{11}, A_{22}, \dots A_{12} \dots$ will in general involve $t$ explicitly as well as implicitly through the co-ordinates $q_1, q_2, \dots$. Again, we find

$$\Sigma m(\dot x\delta x + \dot y\delta y + \dot z\delta z) = (a_1 + A_{11}\dot q_1 + A_{12}\dot q_2 + \dots)\delta q_1$$
$$+ (a_2 + A_{21}\dot q_1 + A_{22}\dot q_2 + \dots)\delta q_2 + \dots$$
$$= \frac{\partial T}{\partial \dot q_1}\delta q_1 + \frac{\partial T}{\partial \dot q_2}\delta q_2 + \dots$$
$$= p_1\delta q_1 + p_2\delta q_2 + \dots, \qquad (6)$$

where $p_r$ is defined as in § 1 (13). The derivation of Lagrange's

equations then follows exactly as before. It is to be noted that the equation § 2 (17) does not as a rule now hold. The proof involved the assumption that T is a homogeneous quadratic function of the velocities $\dot q_1, \dot q_2 \ldots$.

It has been pointed out by Hayward that Vieille's case can be brought under Lagrange's by introducing a new co-ordinate ($\theta$) in place of $t$, so far as it appears explicitly in the relations (1). We have then

$$2T = a_0\dot\theta^2 + 2(a_1\dot q_1 + a_2\dot q_2 + \ldots)\dot\theta + A_{11}\dot q_1^2 + A_{22}\dot q_2^2 + \ldots + 2A_{12}\dot q_1\dot q_2 + \ldots . \quad (7)$$

The equations of motion will be as in § 2 (10), with the additional equation

$$\frac{d}{dt}\frac{\partial T}{\partial \dot\theta} - \frac{\partial T}{\partial \theta} = \Theta, \quad . \quad . \quad . \quad . \quad (8)$$

where $\Theta$ is the force corresponding to the co-ordinate $\theta$. We may suppose $\Theta$ to be adjusted so as to make $\ddot\theta = 0$, and in the remaining equations nothing is altered if we write $t$ for $\theta$ before, instead of after, the differentiations. The reason why the equation § 2 (17) no longer holds is that we should require to add a term $\Theta\dot\theta$ on the right-hand side; this represents the rate at which work is being done by the constraining forces required to keep $\dot\theta$ constant.

As an example, let $x, y, z$ be the co-ordinates of a particle relative to axes fixed in a solid which is free to rotate about the axis of $z$. If $\theta$ be the angular co-ordinate of the solid, we find without difficulty

$$2T = m(\dot x^2 + \dot y^2 + \dot z^2) + 2\dot\theta m(x\dot y - y\dot x) + \{I + m(x^2 + y^2)\}\dot\theta^2, \quad . \quad (9)$$

where I is the moment of inertia of the solid. The equations of motion, viz.,

$$\frac{d}{dt}\frac{\partial T}{\partial \dot x} - \frac{\partial T}{\partial x} = X, \quad \frac{d}{dt}\frac{\partial T}{\partial \dot y} - \frac{\partial T}{\partial y} = Y, \quad \frac{d}{dt}\frac{\partial T}{\partial \dot z} - \frac{\partial T}{\partial z} = Z, \quad (10)$$

and

$$\frac{d}{dt}\frac{\partial T}{\partial \dot\theta} - \frac{\partial T}{\partial \theta} = \Theta, \quad . \quad . \quad . \quad . \quad (11)$$

become

$$m(\ddot x - 2\dot\theta\dot y - x\dot\theta^2 - y\ddot\theta) = X, \quad m(\ddot y + 2\dot\theta\dot x - y\dot\theta^2 + x\ddot\theta) = Y, \quad m\ddot z = Z, \quad (12)$$

and

$$\frac{d}{dt}[\{(I + m(x^2 + y^2)\}\dot\theta + m(x\dot y - y\dot x)] = \Theta. \quad . \quad . \quad (13)$$

If we suppose $\Theta$ adjusted so as to maintain $\ddot\theta = 0$, or (again) if we suppose the moment of inertia I to be infinitely great, we obtain the familiar equations of motion relative to moving axes, viz.,

$$m(\ddot x - 2\omega\dot y - \omega^2 x) = X, \quad m(\ddot y + 2\omega\dot x - \omega^2 y) = Y, \quad m\ddot z = Z, \quad . \quad (14)$$

where $\omega$ has been written for $\dot\theta$. These are the equations which we should have obtained by applying Lagrange's rule at once to the formula

$$2T = m(\dot x^2 + \dot y^2 + \dot z^2) + 2m\omega(x\dot y - y\dot x) + m\omega^2(x^2 + y^2), \quad . \quad (15)$$

which gives the kinetic energy of the particle referred to axes rotating with the constant angular velocity $\omega$.

**Rotating axes.**

More generally, we might apply Lagrange's method to find the equations of motion of a system whose configuration relative to axes rotating with constant angular velocity ($\omega$) is defined by means of generalized co-ordinates $q_1, q_2, \ldots q_n$, writing

$$2T = \Sigma m(\dot x^2 + \dot y^2 + \dot z^2) + 2\omega\Sigma m(x\dot y - y\dot x) + \omega^2\Sigma m(x^2 + y^2)$$
$$= 2\mathfrak{T} + 2\omega\Sigma m(x\dot y - y\dot x) + 2T_0, \quad . \quad . \quad . \quad . \quad (16)$$

say. This problem is interesting on account of its bearing on the kinetic theory of the tides. The details of the work would occupy too much space, but the result may be stated. Assuming that the Cartesian co-ordinates $x, y, z$ of any particle relative to the moving axes are functions of $q_1, q_2, \ldots q_n$, of the form § 1 (1), we find, after cancelling a number of terms, that the typical equation is

$$\frac{d}{dt}\frac{\partial \mathfrak{T}}{\partial \dot q_r} - \frac{\partial \mathfrak{T}}{\partial q_r} + (r,1)\dot q_1 + (r,2)\dot q_2 + \ldots + (r,s)\dot q_s + \ldots - \frac{\partial T_0}{\partial q_r} = Q_r, \quad (17)$$

where

$$(r, s) = 2\omega \,.\, \Sigma m \frac{\partial(x, y)}{\partial(q_s, q_r)}. \quad . \quad . \quad . \quad (18)$$

It is to be noticed that

$$(r, r) = 0, \quad (r, s) = -(s, r). \quad . \quad . \quad (19)$$

The conditions of relative equilibrium are

$$Q_r = -\frac{\partial T_0}{\partial q_r}, \quad . \quad . \quad . \quad . \quad (20)$$

or, in case the forces $Q_r$ depend only on the co-ordinates $q_1, q_2, \ldots$, and are conservative,

$$\frac{\partial}{\partial q_r}(V - T_0) = 0, \quad . \quad . \quad . \quad . \quad (21)$$

*i.e.*, the value of $V - T_0$ must be *stationary*.

If we multiply (17) by $\dot q_r$, and sum the result for $r = 1, 2, 3, \ldots n$, we find, taking account of (19),

$$\frac{d}{dt}(\mathfrak{T} - T_0) = Q_1\dot q_1 + Q_2\dot q_2 + \ldots, \quad . \quad . \quad (22)$$

or, in the case of conservative forces,

$$\mathfrak{T} + V - T_0 = \text{const.} \quad . \quad . \quad . \quad (23)$$

This may be called the equation of relative energy. It may, of course, be easily established from first principles without the use of generalized co-ordinates.

**Constrained systems.**

We have still to notice the modifications which Lagrange's equations undergo when the co-ordinates $q_1, q_2, \ldots q_n$ are not all independently variable. In the first place, we may suppose them connected by a number $m$ ($< n$) of relations of the type

$$A(t, q_1, q_2, \ldots q_n) = 0, \quad B(t, q_1, q_2, \ldots q_n) = 0, \quad \&c., \quad (24)$$

These may be interpreted as introducing partial constraints into a previously free system. The variations $\delta q_1, \delta q_2, \ldots \delta q_n$ in the expressions (6) and (7) of § 2 which are to be equated are no longer independent, but are subject to the relations

$$\frac{\partial A}{\partial q_1}\delta q_1 + \frac{\partial A}{\partial q_2}\delta q_2 + \ldots = 0, \quad \frac{\partial B}{\partial q_1}\delta q_1 + \frac{\partial B}{\partial q_2}\delta q_2 + \ldots = 0, \quad \&c. \quad (25)$$

Introducing indeterminate multipliers $\lambda, \mu, \ldots$, one for each of these equations, we obtain in the usual manner $n$ equations of the type

$$\frac{d}{dt}\frac{\partial T}{\partial \dot q_r} - \frac{\partial T}{\partial q_r} = Q_r + \lambda\frac{\partial A}{\partial q_r} + \mu\frac{\partial B}{\partial q_r} + \ldots, \quad . \quad . \quad (26)$$

in place of § 2 (10). These equations, together with (24), serve to determine the $n$ co-ordinates $q_1, q_2, \ldots q_n$ and the $m$ multipliers $\lambda, \mu, \ldots$.

Again, it may happen that although there are no prescribed relations between the co-ordinates $q_1, q_2, \ldots q_n$, yet from the circumstances of the problem certain geometrical conditions are imposed on their *variations*, thus

$$A_1\delta q_1 + A_2\delta q_2 + \ldots = 0, \quad B_1\delta q_1 + B_2\delta q_2 + \ldots = 0, \quad \&c., \quad (27)$$

where the coefficients are functions of $q_1, q_2, \ldots q_n$ and (possibly) of $t$. It is assumed that these equations are not integrable as regards the variables $q_1, q_2, \ldots q_n$; otherwise, we fall back on the previous conditions. Cases of the present type arise, for instance, in ordinary dynamics when we have a solid rolling on a (fixed or moving) surface. The six co-ordinates which serve to specify the position of the solid at any instant are not subject to any necessary relation, but the conditions to be satisfied at the point of contact impose three conditions of the form (27). The general equations of motion are obtained, as before, by the method of indeterminate multipliers, thus

$$\frac{d}{dt}\frac{\partial T}{\partial \dot q_r} - \frac{\partial T}{\partial q_r} = Q_r + \lambda A_r + \mu B_r + \ldots . \quad . \quad . \quad (28)$$

The co-ordinates $q_1, q_2, \ldots q_n$, and the indeterminate multipliers $\lambda, \mu, \ldots$ are determined by these equations and by the velocity-conditions corresponding to (27). When $t$ does not appear explicitly in the coefficients, these velocity-conditions take the forms

$$A_1\dot q_1 + A_2\dot q_2 + \ldots = 0, \quad B_1\dot q_1 + B_2\dot q_2 + \ldots = 0, \quad \&c. \quad . \quad (29)$$

*Hamiltonian Equations of Motion.*

§ 4. In the Hamiltonian form of the equations of motion of a conservative system with unvarying relations, the kinetic energy is supposed expressed in terms of the *momenta* $p_1, p_2, \ldots$ and the co-ordinates $q_1, q_2, \ldots$, as in § 1 (19). Since the symbol $\delta$ now denotes a variation extending to the co-ordinates as well as to the momenta, we must add to the last member of § 1 (21) terms of the types

$$\frac{\partial T}{\partial q_1}\delta q_1 + \frac{\partial T'}{\partial q_1}\delta q_1 + \ldots . \quad . \quad . \quad . \quad (1)$$

Since the variations $\delta p_1, \delta p_2, \ldots \delta q_1, \delta q_2, \ldots$ may be taken to be independent, we infer the equations § 1 (23) as before, together with

$$\frac{\partial T}{\partial q_1} = -\frac{\partial T'}{\partial q_1}, \quad \frac{\partial T}{\partial q_2} = -\frac{\partial T'}{\partial q_2}, \quad \ldots, \quad . \quad . \quad (2)$$

Hence the Lagrangian equations § 2 (14) transform into

$$\dot p_1 = -\frac{\partial}{\partial q_1}(T' + V), \quad \dot p_2 = -\frac{\partial}{\partial q_2}(T' + V), \quad \ldots . \quad (3)$$

If we write

$$H = T' + V, \quad . \quad . \quad . \quad . \quad (4)$$

so that H denotes the *total energy* of the system, supposed expressed in terms of the new variables, we get

$$\dot p_1 = -\frac{\partial H}{\partial q_1}, \quad \dot p_2 = -\frac{\partial H}{\partial q_2}, \quad \ldots \quad . \quad . \quad (5)$$

If to these we join the equations

$$\dot q_1 = \frac{\partial H}{\partial p_1}, \quad \dot q_2 = \frac{\partial H}{\partial p_2}, \quad \ldots, \quad . \quad . \quad . \quad (6)$$

which follow at once from § 1 (23), since V does not involve $p_1, p_2, \ldots$, we obtain a complete system of differential equations *of the first order* for the determination of the motion.

The equation of energy is verified immediately by (5) and (6), since these make

$$\frac{d\mathrm{H}}{dt}=\frac{\partial \mathrm{H}}{\partial p_1}\dot{p}_1+\frac{\partial \mathrm{H}}{\partial p_2}\dot{p}_2+\ldots+\frac{\partial \mathrm{H}}{\partial q_1}\dot{q}_1+\frac{\partial \mathrm{H}}{\partial q_2}\dot{q}_2+\ldots=0. \quad . \quad (7)$$

The Hamiltonian transformation is extended to the case of varying relations as follows. Instead of (4) we write

$$\mathrm{H}=p_1\dot{q}_1+p_2\dot{q}_2+\ldots-\mathrm{T}+\mathrm{V}, \quad . \quad . \quad . \quad (8)$$

and imagine H to be expressed in terms of the momenta $p_1, p_2, \ldots$, the co-ordinates $q_1, q_2, \ldots$, and the time. The internal forces of the system are assumed to be conservative, with the potential energy V. Performing the variation $\delta$ on both sides, we find

$$\delta \mathrm{H}=\dot{q}_1\delta p_1+\ldots-\frac{\partial \mathrm{T}}{\partial q_1}\delta q_1+\frac{\partial \mathrm{V}}{\partial q_1}\delta q+\ldots, \quad . \quad (9)$$

terms which cancel in virtue of the definition of $p_1, p_2, \ldots$ being omitted. Since $\delta p_1, \delta p_2, \ldots, \delta q_1, \delta q_2 \ldots$ may be taken to be independent, we infer

$$\dot{q}_1=\frac{\partial \mathrm{H}}{\partial p_1}, \quad \dot{q}_2=\frac{\partial \mathrm{H}}{\partial p_2}, \ \ldots, \quad . \quad . \quad . \quad (10)$$

and

$$\frac{\partial}{\partial q_1}(\mathrm{T}-\mathrm{V})=-\frac{\partial \mathrm{H}}{\partial q_1}, \quad \frac{\partial}{\partial q_2}(\mathrm{T}-\mathrm{V})=-\frac{\partial \mathrm{H}}{\partial q_2}, \ \ldots \quad . \quad (11)$$

It follows from (11) that

$$\dot{p}_1=-\frac{\partial \mathrm{H}}{\partial q_1}, \quad \dot{p}_2=-\frac{\partial \mathrm{H}}{\partial q_2}, \ \ldots. \quad . \quad . \quad (12)$$

The equations (10) and (12) have the same form as above, but H is no longer equal to the energy of the system.

### *Cyclic Systems.*

§ 5. A *cyclic* or *gyrostatic* system is characterized by the following properties. In the first place, the kinetic energy is not affected if we alter the absolute values of certain of the co-ordinates, which we will denote by $\chi, \chi', \chi'', \ldots$, provided the remaining co-ordinates $q_1, q_2, \ldots q_m$ and the velocities, including of course the velocities $\dot{\chi}, \dot{\chi}', \dot{\chi}'', \ldots$, are unaltered. Secondly, there are no forces acting on the system of the types $\chi, \chi', \chi'', \ldots$. This case arises, for example, when the system includes gyrostats which are free to rotate about their axes, the co-ordinates $\chi, \chi', \chi'', \ldots$ then being the angular co-ordinates of the gyrostats relatively to their frames. Again, in theoretical hydrodynamics we have the problem of moving solids in a frictionless liquid; the ignored co-ordinates $\chi, \chi', \chi'', \ldots$ then refer to the fluid, and are infinite in number. The same question presents itself in various physical speculations where certain phenomena are ascribed to the existence of *latent motions* in the ultimate constituents of matter. The general theory of such systems has been treated by Routh, Lord Kelvin, and Helmholtz.

***Routh's equations.***

If we suppose the kinetic energy T to be expressed, as in Lagrange's method, in terms of the co-ordinates and the velocities, the equations of motion corresponding to $\chi, \chi', \chi'', \ldots$ reduce, in virtue of the above hypotheses, to the forms

$$\frac{d}{dt}\frac{\partial \mathrm{T}}{\partial \dot{\chi}}=0, \quad \frac{d}{dt}\frac{\partial \mathrm{T}}{\partial \dot{\chi}'}=0, \quad \frac{d}{dt}\frac{\partial \mathrm{T}}{\partial \dot{\chi}''}=0, \ \ldots, \quad . \quad (1)$$

whence

$$\frac{\partial \mathrm{T}}{\partial \dot{\chi}}=\kappa, \quad \frac{\partial \mathrm{T}}{\partial \dot{\chi}'}=\kappa', \quad \frac{\partial \mathrm{T}}{\partial \dot{\chi}''}=\kappa'', \ \ldots, \quad . \quad . \quad (2)$$

where $\kappa, \kappa', \kappa'', \ldots$ are the constant momenta corresponding to the cyclic co-ordinates $\chi, \chi', \chi'', \ldots$. These equations are linear in $\dot{\chi}, \dot{\chi}', \dot{\chi}'', \ldots$; solving them with respect to these quantities and substituting in the remaining Lagrangian equations, we obtain $m$ differential equations to determine the remaining co-ordinates $q_1, q_2, \ldots q_m$. The object of the present investigation is to ascertain the general form of the resulting equations. The retained co-ordinates $q_1, q_2, \ldots q_m$ may be called (for distinction) the *palpable* co-ordinates of the system; in many practical questions they are the only co-ordinates directly in evidence.

If, as in § 1 (25), we write

$$\Theta=\mathrm{T}-\kappa\dot{\chi}-\kappa'\dot{\chi}'-\kappa''\dot{\chi}'-\ldots, \quad . \quad . \quad . \quad (3)$$

and imagine $\Theta$ to be expressed by means of (2) as a quadratic function of $\dot{q}_1, \dot{q}_2, \ldots \dot{q}_m, \kappa, \kappa', \kappa'', \ldots$ with coefficients which are in general functions of the co-ordinates $q_1, q_2, \ldots q_m$, then, performing the operation $\delta$ on both sides, we find

$$\frac{\partial \Theta}{\partial \dot{q}_1}\delta\dot{q}_1+\ldots+\frac{\partial \Theta}{\partial \kappa}\delta\kappa+\ldots+\frac{\partial \Theta}{\partial q_1}\delta q_1+\ldots=\frac{\partial \mathrm{T}}{\partial \dot{q}_1}\delta\dot{q}_1+\ldots+\frac{\partial \mathrm{T}}{\partial q_1}\delta q_1+\ldots$$
$$+\frac{\partial \mathrm{T}}{\partial \dot{\chi}}\delta\dot{\chi}+\ldots+\frac{\partial \mathrm{T}}{\partial \chi_1}\delta q_1+\ldots-\kappa\delta\dot{\chi}-\dot{\chi}\delta\kappa-\ldots. \quad . \quad (4)$$

Omitting the terms which cancel by (2), we find

$$\frac{\partial \mathrm{T}}{\partial q_1}=\frac{\partial \Theta}{\partial \dot{q}_1}, \quad \frac{\partial \mathrm{T}}{\partial \dot{q}_2}=\frac{\partial \Theta}{\partial \dot{q}_2}, \ \ldots, \quad . \quad . \quad . \quad (5)$$

$$\frac{\partial \mathrm{T}}{\partial q_1}=\frac{\partial \Theta}{\partial q_1}, \quad \frac{\partial \mathrm{T}}{\partial q_2}=\frac{\partial \Theta}{\partial q_2}, \ \ldots, \quad . \quad . \quad . \quad (6)$$

$$\dot{\chi}=-\frac{\partial \Theta}{\partial \kappa}, \quad \dot{\chi}'=-\frac{\partial \Theta}{\partial \kappa'}, \quad \dot{\chi}''=-\frac{\partial \Theta}{\partial \kappa''}, \quad . \quad . \quad (7)$$

Substituting in § 2 (10), we have

$$\frac{d}{dt}\frac{\partial \Theta}{\partial \dot{q}_1}-\frac{\partial \Theta}{\partial q_1}=\mathrm{Q}_1, \quad \frac{d}{dt}\frac{\partial \Theta}{\partial \dot{q}_2}-\frac{\partial \Theta}{\partial q_2}=\mathrm{Q}_2, \ \ldots \ldots \quad . \quad (8)$$

These are Routh's forms of the modified Lagrangian equations. Equivalent forms were obtained independently by Helmholtz at a later date.

The function $\Theta$ is made up of three parts, thus

$$\Theta=\Theta_{2,0}+\Theta_{1,1}+\Theta_{0,2}, \quad . \quad . \quad . \quad (9)$$

***Kelvin's equations.***

where $\Theta_{2,0}$ is a homogeneous quadratic function of $\dot{q}_1, \dot{q}_2 \ldots, \dot{q}_m$, $\Theta_{0,2}$ is a homogeneous quadratic function of $\kappa, \kappa', \kappa'', \ldots$, whilst $\Theta_{1,1}$ consists of products of the velocities $\dot{q}_1, \dot{q}_2, \ldots \dot{q}_m$ into the momenta $\kappa, \kappa', \kappa'' \ldots$. Hence from (3) and (7) we have

$$\mathrm{T}=\Theta-\left(\kappa\frac{\partial \Theta}{\partial \kappa}+\kappa'\frac{\partial \Theta}{\partial \kappa'}+\kappa''\frac{\partial \Theta}{\partial \kappa''}+\ldots\right)$$
$$=\Theta_{2,0}-\Theta_{0,2}. \quad . \quad . \quad . \quad . \quad . \quad (10)$$

If, as in § 1 (30), we write this in the form

$$\mathrm{T}=\mathfrak{T}+\mathrm{K}, \quad . \quad . \quad . \quad . \quad . \quad (11)$$

then (3) may be written

$$\Theta=\mathfrak{T}-\mathrm{K}+\beta_1\dot{q}_1+\beta_2\dot{q}_2+\ldots. \quad . \quad . \quad (12)$$

where $\beta_1, \beta_2, \ldots$ are linear functions of $\kappa, \kappa', \kappa'', \ldots$ say

$$\beta_r=\alpha_r\kappa+\alpha'_r\kappa'+\alpha''_r\kappa''+\ldots \quad . \quad . \quad . \quad (13)$$

the coefficients $\alpha_r, \alpha'_r, \alpha''_r, \ldots$ being in general functions of the co-ordinates $q_1, q_2, \ldots q_m$. Evidently $\beta_r$ denotes that part of the momentum-component $\partial\Theta/\partial\dot{q}_r$ which is due to the cyclic motions. Now

$$\frac{d}{dt}\frac{\partial \Theta}{\partial \dot{q}_r}=\frac{d}{dt}\left(\frac{\partial \mathfrak{T}}{\partial \dot{q}_r}+\beta_r\right)=\frac{d}{dt}\frac{\partial \mathfrak{T}}{\partial \dot{q}_r}+\frac{\partial \beta_r}{\partial q_1}\dot{q}_1+\frac{\partial \beta_r}{\partial q_2}\dot{q}_2+\ldots, \quad (14)$$

$$\frac{\partial \Theta}{\partial q_r}=\frac{\partial \mathfrak{T}}{\partial q_r}-\frac{\partial \mathrm{K}}{\partial q_r}+\frac{\partial \beta_1}{\partial q_r}\dot{q}_1+\frac{\partial \beta_2}{\partial q_r}\dot{q}_2+\ldots. \quad . \quad . \quad (15)$$

Hence, substituting in (8), we obtain the typical equation of motion of a gyrostatic system in the form

$$\frac{d}{dt}\frac{\partial \mathfrak{T}}{\partial \dot{q}_r}-\frac{\partial \mathfrak{T}}{\partial q_r}+(r,1)\dot{q}_1+(r,2)\dot{q}_2+\ldots+(r,s)\dot{q}_s+\ldots+\frac{\partial \mathrm{K}}{\partial q_r}=\mathrm{Q}_r, \quad (16)$$

where

$$(r,s)=\frac{\partial \beta_r}{\partial q_s}-\frac{\partial \beta_s}{\partial q_r}. \quad . \quad . \quad . \quad (17)$$

This form is due to Lord Kelvin. When $q_1, q_2, \ldots q_m$ have been determined, as functions of the time, the velocities corresponding to the cyclic co-ordinates can be found, if required, from the relations (7), which may be written

$$\left.\begin{aligned}\dot{\chi}&=\frac{\partial \mathrm{K}}{\partial \kappa}-\alpha_1\dot{q}_1-\alpha_2\dot{q}_2-\ldots,\\ \dot{\chi}'&=\frac{\partial \mathrm{K}}{\partial \kappa'}-\alpha'_1\dot{q}_1-\alpha'_2\dot{q}_2-\ldots,\\ &\&c., \&c.\end{aligned}\right\} \quad . \quad . \quad (18)$$

It is to be particularly noticed that

$$(r,r)=0, \quad (r,s)=-(s,r). \quad . \quad . \quad . \quad (19)$$

Hence, if in (16) we put $r=1, 2, 3, \ldots m$, and multiply by $\dot{q}_1, \dot{q}_2, \ldots \dot{q}_m$ respectively, and add, we find

$$\frac{d}{dt}(\mathfrak{T}+\mathrm{K})=\mathrm{Q}_1\dot{q}_1+\mathrm{Q}_2\dot{q}_2+\ldots \quad . \quad . \quad (20)$$

or, in the case of a conservative system

$$\mathfrak{T}+\mathrm{V}+\mathrm{K}=\text{const.} \quad . \quad . \quad . \quad (21)$$

which is the equation of energy.

The equations (16) include § 3 (17) as a particular case, the eliminated co-ordinate being the angular co-ordinate of a rotating solid having an infinite moment of inertia.

In the particular case where the cyclic momenta $\kappa, \kappa', \kappa'', \ldots$ are all zero, (16) reduces to

$$\frac{d}{dt}\frac{\partial \mathfrak{T}}{\partial \dot{q}_r}-\frac{\partial \mathfrak{T}}{\partial q_r}=\mathrm{Q}_r. \quad . \quad . \quad . \quad (22)$$

The form is the same as in § 2, and the system now behaves, as regards the co-ordinates $q_1, q_2, \ldots q_m$, exactly like the acyclic type there contemplated. These co-ordinates do not, however,

now fix the position of every particle of the system. For example, if by suitable forces the system be brought back to its initial configuration (so far as this is defined by $q_1, q_2, \dots q_m$), after performing any evolutions, the ignored co-ordinates $\chi, \chi', \chi'', \dots$ will not in general return to their original values.

If in Lagrange's equations § 2 (10) we reverse the sign of the time-element $dt$, the equations are unaltered. The motion is therefore reversible; that is to say, if as the system is passing through any configuration its velocities $\dot{q}_1, \dot{q}_2, \dots \dot{q}_n$ be all reversed, it will (if the forces be the same in the same configuration) retrace its former path. But it is important to observe that the statement does not in general hold of a gyrostatic system; the terms of (16), which are linear in $\dot{q}_1, \dot{q}_2, \dots \dot{q}_m$, change sign with $dt$, whilst the others do not. Hence the motion of a gyrostatic system is not reversible, unless indeed we reverse the cyclic motions as well as the velocities $\dot{q}_1, \dot{q}_2, \dots \dot{q}_m$. For instance, the precessional motion of a top cannot be reversed unless we reverse the spin.

***Kineto-statics.***

The *conditions of equilibrium* of a system with latent cyclic motions are obtained by putting $\dot{q}_1 = 0$, $\dot{q}_2 = 0, \dots \dot{q}_m = 0$ in (16); viz., they are

$$Q_1 = \frac{\partial K}{\partial q_1}, \quad Q_2 = \frac{\partial K}{\partial q_2}, \quad \dots \quad . \quad . \quad . \quad (23)$$

These may of course be obtained independently. Thus if the system be guided from (apparent) rest in the configuration $(q_1, q_2, \dots q_m)$ to rest in the configuration $(q_1 + \delta q_1, q_2 + \delta q_2, \dots q_m + \delta q_m)$, the work done by the forces must be equal to the increment of the kinetic energy. Hence

$$Q_1 \delta q_1 + Q_2 \delta q_2 + \dots = \delta K, \quad . \quad . \quad . \quad (24)$$

which is equivalent to (23). The conditions are the same as for the equilibrium of a system without latent motion, but endowed with potential energy K. This is important from a physical point of view, as showing how energy which is apparently potential may in its ultimate essence be kinetic.

By means of the formulæ (18), which now reduce to

$$\dot{\chi} = \frac{\partial K}{\partial \kappa}, \quad \dot{\chi}' = \frac{\partial K}{\partial \kappa'}, \quad \dot{\chi}'' = \frac{\partial K}{\partial \kappa''}, \dots, \quad . \quad . \quad (25)$$

K may also be expressed as a homogeneous quadratic function of the cyclic velocities $\dot{\chi}, \dot{\chi}', \dot{\chi}'', \dots$. Denoting it in this form by $T_0$, we have

$$\delta(T_0 + K) = 2\delta K = \delta(\kappa\dot{\chi} + \kappa'\dot{\chi}' + \kappa''\dot{\chi}'' + \dots) . \quad . \quad (26)$$

Performing the variations, and omitting the terms which cancel by (2) and (25), we find

$$\frac{\partial T_0}{\partial q_1} = -\frac{\partial K}{\partial q_1}, \quad \frac{\partial T_0}{\partial q_2} = -\frac{\partial K}{\partial q_2}, \quad \dots \quad . \quad . \quad (27)$$

so that the formulæ (23) become

$$Q_1 = -\frac{\partial T_0}{\partial q_1}, \quad Q_2 = -\frac{\partial T_0}{\partial q_2}, \quad \dots \quad . \quad . \quad (28)$$

A simple example is furnished by the top (§ 2). The cyclic co-ordinates being $\psi$, $\phi$, we find

$$2\mathfrak{T} = A\dot{\theta}^2, \quad 2K = \frac{(\mu - \nu\cos\theta)^2}{A\sin^2\theta} + \frac{\nu^2}{C},$$

$$2T_0 = A\sin^2\theta\dot{\psi}^2 + C(\dot{\phi} + \dot{\psi}\cos\theta)^2, . \quad . \quad (29)$$

whence we may verify that $\partial T_0/\partial\theta = -\partial K/\partial\theta$ in accordance with (27). And the condition of equilibrium

$$\frac{\partial K}{\partial \theta} = -\frac{\partial V}{\partial \theta} \quad . \quad . \quad . \quad . \quad (30)$$

gives the condition of steady precession, § 2 (26).

*Stability of Equilibrium and of Steady Motion.*

***Statical stability.***

§ 6. The theory of the small oscillations of a conservative system about a configuration of equilibrium, originated by Lagrange, has been greatly developed by Thomson and Tait, Routh, and Lord Rayleigh. The details of the matter belong properly to acoustics, but some reference may be made to the important but rather difficult question of stability. If we neglect small quantities of the second order in the velocities and the displacements, Lagrange's equations assume a linear form, and the deviation of any co-ordinate from its equilibrium value is expressed by a series of terms of the type $Ce^{\pm\lambda t}$, the admissible values of $\lambda^2$ being given by an algebraic equation of degree $n$. In order that the expressions for the deviations may not admit of indefinite increase, the values of $\lambda$ must be purely imaginary (*i.e.*, of the form $i\sigma$), so that the exponentials become replaced by circular functions of $t$. It is found that this will be the case if, and only if, the potential energy V is a minimum in the configuration of equilibrium. Accordingly, it is usual to say that the necessary and sufficient condition for stability is that the equilibrium-value of V should be a minimum.

The validity of this inference has in recent times been contested. It is pointed out that since Lagrange's approximate equations become less and less accurate as the deviation from the equilibrium configuration increases, it is a matter for examination how far rigorous conclusions as to the ultimate extent of the deviation can be based upon them. Some researches in this direction have been instituted by Liapounoff, Poincaré, and others, but the question cannot yet be regarded as completely resolved.

That the occurrence of a minimum value of V is a *sufficient* condition of stability was shown independently by Dirichlet. In the motion consequent on any slight disturbance the total energy $T + V$ is constant, and since T is essentially positive, it follows that V can never exceed its equilibrium value by more than a slight amount depending on the energy of the disturbance. This implies, on the present hypothesis, that there is an upper limit to the deviation of each co-ordinate from its equilibrium value; moreover, this limit diminishes indefinitely with the energy of the original disturbance. No such simple proof is available to show without qualification that the above condition is *necessary*. If, however, we recognize the existence of dissipative forces called into play by any motion of the system, the conclusion can be drawn as follows. However slight these forces may be, the total energy $T + V$ must continually diminish so long as the velocities $\dot{q}_1, \dot{q}_2, \dots \dot{q}_n$ differ from zero. Hence, if the system be started from rest in a configuration for which V is less than in the equilibrium configuration, this expression must still further decrease (since T cannot be negative), and it is evident that either the system will finally come to rest in some new equilibrium configuration, or V will in the long run diminish indefinitely. This argument is due to Thomson and Tait.

***Kinetic stability.***

A little consideration will show that a good deal of the obscurity which attaches to the question arises from the want of a sufficiently precise definition of what is meant by "stability." The same difficulty is encountered, in an aggravated form, when we pass to the question of stability of motion. The various definitions of stability which have been propounded by different writers are examined critically by Klein and Sommerfeld in their book on the theory of the top. Rejecting previous definitions, they base their criterion of stability on the character of the changes produced in the *path* of the system by small arbitrary disturbing impulses. If the undisturbed path be the *limiting form* of the disturbed path when the impulses are indefinitely diminished, it is said to be stable, but not otherwise. For instance, the vertical fall of a particle under gravity is reckoned as stable, although for a *given* impulsive disturbance, however small, the deviation of the particle's position at any time $t$ from the position which it would have occupied in the original motion increases indefinitely with $t$. Even this criterion, as the writers quoted themselves recognize, is not free from ambiguity unless the phrase "limiting form," as applied to a path, be strictly defined. It appears, moreover, that a definition which is analytically precise may not in all cases be easy to reconcile with geometrical prepossessions.

A special form of the problem, of great interest, presents itself in the steady motion of a gyrostatic system, when the non-eliminated co-ordinates $q_1, q_2, \dots q_m$ all vanish (see § 5). This has been discussed by Routh, Thomson and Tait, and Poincaré. These writers treat the question, by an extension of Lagrange's method, as a problem of small oscillations. Whether we adopt the notion of stability which this implies, or take up the position of Klein and Sommerfeld, there is no difficulty in showing that stability is ensured if $V + K$ be a minimum as regards variations of $q_1, q_2, \dots q_m$. The proof is the same as that of Dirichlet for the case of statical stability. It is easily seen that, in the notation of § 5, an equivalent condition is that $V - T_0$ should be a minimum for the same variations.

We can illustrate this condition from the case of the top, where, in our previous notation,

$$V + K = Mgh\cos\theta + \frac{(\mu - \nu\cos\theta)^2}{2A\sin^2\theta} + \frac{\nu^2}{2C} . \quad . \quad . \quad (1)$$

To examine whether the steady motion with the centre of gravity vertically above the pivot is stable, we must put $\mu = \nu$. We then find without difficulty that $V + K$ is a minimum provided $\nu^2 \geqq 4AMgh$. The method of small oscillations gave us the condition $\nu^2 > 4AMgh$, and indicated instability in the cases $\nu^2 \leqq 4AMgh$. The present criterion can also be applied to show that the steady precessional motions in which the axis has a constant inclination to the vertical are stable.

The question remains, as before, whether it is *essential* for stability that $V + K$ should be a minimum. It appears that from the point of view of the theory of small oscillations it is not essential, and that there may even be stability when $V + K$ is a maximum. The precise conditions, which are of a somewhat elaborate character, have been formulated by Routh. An important distinction has, however, been established by Thomson and Tait, and by Poincaré, between what we may call *ordinary* or *accidental* stability (which is stability in the above sense) and *permanent* or *secular* stability, which means stability when regard is had to possible dissipative

forces called into play whenever the co-ordinates $q_1, q_2, \ldots q_m$ vary. Since the total energy of the system at any instant is given (in the notation of § 5) by an expression of the form $\mathfrak{T} + \mathrm{V} + \mathrm{K}$, where $\mathfrak{T}$ cannot be negative, the argument of Thomson and Tait, given above for the statical question, shows that it is a necessary as well as a sufficient condition for secular stability that $\mathrm{V} + \mathrm{K}$ should be a minimum.

*Principle of Least Action.*

§ 7. The preceding theories give us statements applicable to the system at any one instant of its motion. We now come to a series of theorems relating to the whole motion of the system between any two configurations through which it passes, viz., we consider the actual motion and compare it with other imaginable motions, differing infinitely little from it, between the same two configurations. We use the symbol $\delta$ to denote the transition from the actual to any one of the hypothetical motions.

***Stationary action.***

The best-known theorem of this class is that of *Least Action*, originated by Maupertuis, but first put in a definite form by Lagrange. The "action" of a single particle in passing from one position to another is the space-integral of the momentum, or the time-integral of the *vis viva*. The action of a dynamical system is the sum of the actions of its constituent particles, and is accordingly given by the formula

$$\mathrm{A} = \Sigma \int mvds = \Sigma \int mv^2 dt = 2\int \mathrm{T}dt. \quad . \quad . \quad (1)$$

The theorem referred to asserts that the free motion of a conservative system between any two given configurations is characterized by the property

$$\delta \mathrm{A} = 0, \quad . \quad . \quad . \quad . \quad . \quad . \quad (2)$$

provided the total energy have the same constant value in the varied motion as in the actual motion. The proof, from first principles, has been given under MECHANICS (*Ency. Brit.* vol. xv. pp. 723-26), where it is also shown how the equation (2), expressed in terms of generalized co-ordinates, leads to Lagrange's equations.

The equation (2), it is to be noticed, merely expresses that the variation of A vanishes *to the first order;* the phrase *stationary action* has therefore been suggested as indicating more accurately what has been proved. The action in the free path between two given configurations is in fact not invariably a minimum, and even when a minimum it need not be the *least possible* subject to the given conditions. Simple illustrations are furnished by the case of a single particle. A particle moving on a smooth surface, and free from extraneous force, will have its velocity constant; hence the theorem in this case resolves itself into

$$\delta \int ds = 0, \quad . \quad . \quad . \quad . \quad (3)$$

*i.e.*, the path must be a geodesic line. Now a geodesic is not necessarily the *shortest* path between two given points on it; for example, on the sphere a great-circle arc ceases to be the shortest path between its extremities when it exceeds 180°. More generally, taking any surface, let a point P, starting from O, move along a geodesic; this geodesic will be a minimum path from O to P until P passes through a point O′ (if such exist), which is the intersection with a consecutive geodesic through O. After this point the minimum property ceases. On an anticlastic surface two geodesics cannot intersect more than once, and each geodesic is therefore a minimum path between any two of its points. These illustrations are due to Jacobi, who has also formulated the general criterion, applicable to all dynamical systems, as follows:—Let O and P denote any two configurations on a natural path of the system. If this be the sole free path from O to P with the prescribed amount of energy, the action from O to P is a minimum. But if there be several distinct paths, let P vary from coincidence with O along the first-named path; the action will then cease to be a minimum when a configuration O′ is reached such that two of the possible paths from O to O′ coincide. For instance, if O and P be positions on the parabolic path of a projectile under gravity, there will be a second path (with the same energy and therefore the same velocity of projection from O), these two paths coinciding when P is at the other extremity (O′, say) of the focal chord through O. The action from O to P will therefore be a minimum for all positions of P short of O′. Two configurations such as O and O′ in the general statement are called conjugate *kinetic foci.* Cf. VARIATION OF AN INTEGRAL, § 6.

Before leaving this topic the connexion of the principle of stationary action with a well-known theorem of optics may be noticed. For the motion of a particle in a conservative field of force the principle takes the form

$$\delta \int vds = 0. \quad . \quad . \quad . \quad . \quad (4)$$

On the corpuscular theory of light $v$ is proportional to the refractive index $\mu$ of the medium, whence

$$\delta \int \mu ds = 0. \quad . \quad . \quad . \quad . \quad (5)$$

For the further development of this result see OPTICS (*Ency. Brit.* vol. xvii.) and WAVE THEORY (*Ency. Brit.* vol. xxiv.).

In the formula (2) the energy in the hypothetical motion is prescribed, whilst the time of transit from the initial to the final configuration is variable. In another theorem, due to Hamilton, the time of transit is prescribed to be the same as in the actual motion, whilst the energy may be different and need not (indeed) be constant. Under these conditions we have

***Hamiltonian principle.***

$$\delta \int_t^{t'} (\mathrm{T} - \mathrm{V}) dt = 0, \quad . \quad . \quad . \quad (6)$$

where $t, t'$ are the prescribed times of passing through the given initial and final configurations. The proof of (6) is simple; we have

$$\begin{aligned}\delta \int_t^{t'} (\mathrm{T} - \mathrm{V}) dt &= \int_t^{t'} (\delta\mathrm{T} - \delta\mathrm{V}) dt = \int_t^{t'} \{\Sigma m(\dot{x}\delta\dot{x} + \dot{y}\delta\dot{y} + \dot{z}\delta\dot{z}) - \delta\mathrm{V}\} dt \\ &= \Big[\Sigma m(\dot{x}\delta x + \dot{y}\delta y + \dot{z}\delta z)\Big]_t^{t'} \\ &\quad - \int_t^{t'} \{\Sigma m(\ddot{x}\delta x + \ddot{y}\delta y + \ddot{z}\delta z) + \delta\mathrm{V}\} dt. \quad . \quad . \quad (7)\end{aligned}$$

The integrated terms vanish at both limits, since by hypothesis the configurations at these instants are fixed; and the terms under the integral sign vanish by D'Alembert's principle.

The fact that in (6) the variation does not affect the time of transit renders the formula easy of application in any system of co-ordinates. Thus, to deduce Lagrange's equations, we have

$$\begin{aligned}\int_t^{t'} (\delta\mathrm{T} - \delta\mathrm{V}) dt &= \int_t^{t'} \left\{ \frac{\partial\mathrm{T}}{\partial\dot{q}_1}\,\delta\dot{q}_1 + \frac{\partial\mathrm{T}}{\partial q_1}\,\delta q_1 + \ldots - \frac{\partial\mathrm{V}}{\partial q_1}\,\delta q_1 - \ldots \right\} dt \\ &= \Big[p_1\delta q + p_2\delta q_2 + \ldots\Big]_t^{t} \\ &\quad - \int_t^{t'} \left\{ \left(\dot{p}_1 - \frac{\partial\mathrm{T}}{\partial q_1} + \frac{\partial\mathrm{V}}{\partial q_1}\right)\delta q_1 + \left(\dot{p}_2 - \frac{\partial\mathrm{T}}{\partial q_2} + \frac{\partial\mathrm{V}}{\partial q_2}\right)\delta q_2 + \ldots \right\} dt \quad (8)\end{aligned}$$

The integrated terms vanish at both limits; and in order that the remainder of the right-hand member may vanish it is necessary that the coefficients of $\delta q_1\ \delta q_2, \ldots$ under the integral sign should vanish for all values of $t$, since the variations in question are independent, and subject only to the condition of vanishing at the limits of integration. We are thus led to Lagrange's equation of motion for a conservative system. It appears that the formula (6) is a convenient as well as a compact embodiment of the whole of ordinary Dynamics.

The modification of the Hamiltonian principle appropriate to the case of cyclic systems has been given by Larmor. If we write, as in § 1 (25),

***Extension to cyclic systems.***

$$\Theta = \mathrm{T} - \kappa\dot{\chi} - \kappa'\dot{\chi}' - \kappa''\dot{\chi}'' - \ldots, \quad . \quad . \quad (9)$$

we shall have

$$\delta \int_t^{t'} (\Theta - \mathrm{V}) dt = 0, \quad . \quad . \quad . \quad (10)$$

provided that the variation does not affect the cyclic momenta $\kappa, \kappa', \kappa'', \ldots$, and that the configurations at times $t$ and $t'$ are unaltered, so far as they depend on the palpable co-ordinates $q_1, q_2, \ldots q_m$. The initial and final values of the ignored co-ordinates *will* in general be affected.

To prove (10) we have, on the above understandings,

$$\begin{aligned}\delta \int_t^{t'} (\Theta - \mathrm{V}) dt &= \int_t^{t'} (\delta\mathrm{T} - \kappa\delta\dot{\chi} - \ldots - \delta\mathrm{V}) dt \\ &= \int_t^{t'} \left(\frac{\partial\mathrm{T}}{\partial\dot{q}_1}\delta\dot{q}_1 + \ldots + \frac{\partial\mathrm{T}}{\partial q_1}\delta q_1 + \ldots - \delta\mathrm{V}\right) dt, \quad . \quad (11)\end{aligned}$$

where terms have been cancelled in virtue of § 5 (2). The last member of (11) represents a variation of the integral

$$\int_t^{t'} (\mathrm{T} - \mathrm{V}) dt$$

on the supposition that $\delta\chi = 0,\ \delta\chi' = 0,\ \delta\chi'' = 0, \ldots$ throughout, whilst $\delta q_1, \delta q_2, \delta q_m$ vanish at times $t$ and $t'$; *i.e.*, it is a variation in which the initial and final configurations are absolutely unaltered. It therefore vanishes as a consequence of the Hamiltonian principle in its original form.

Larmor has also given the corresponding form of the principle of least action. He shows that if we write

$$\mathrm{A} = \int (2\mathrm{T} - \kappa\dot{\chi} - \kappa'\dot{\chi}' - \kappa''\dot{\chi}'' - \ldots) dt, \quad . \quad . \quad (12)$$

then

$$\delta \mathrm{A} = 0, \quad . \quad . \quad . \quad . \quad (13)$$

provided the varied motion takes place with the same constant value of the energy, and with the same constant cyclic momenta,

between the same two configurations, these being regarded as defined by the palpable co-ordinates alone.

*Hamilton's Principal and Characteristic Functions.*

§ 8. In the investigations next to be described a more extended meaning is given to the symbol $\delta$. We will, in the first instance, denote by it an infinitesimal variation of the most general kind, affecting not merely the values of the co-ordinates at any instant, but also the initial and final configurations and the times of passing through them. If we put

**Principal function.**

$$S=\int_t^{t'}(T-V)dt, \quad . \quad . \quad . \quad . \quad (1)$$

we have, then,

$$\delta S=(T'-V')\delta t'-(T-V)\delta t+\int_t^{t'}(\delta T-\delta V)dt$$

$$=(T'-V')\delta t'-(T-V)\delta t+\Big[\Sigma m(\dot{x}\delta x+\dot{y}\delta y+\dot{z}\delta z)\Big]_t^{t'}. \quad . \quad (2)$$

Let us now denote by $x'+\delta x'$, $y'+\delta y'$, $z'+\delta z'$, the final co-ordinates (*i.e.*, at time $t'+\delta t'$) of a particle $m$. In the terms in (2) which relate to the upper limit we must therefore write $\delta x'-\dot{x}'\delta t'$, $\delta y'-\dot{y}'\delta t'$, $\delta z'-\dot{z}'\delta t'$ for $\delta x$, $\delta y$, $\delta z$. With a similar modification at the lower limit, we obtain

$$\delta S=-H\delta\tau+\Sigma m(\dot{x}'\delta x'+\dot{y}'\delta y'+\dot{z}'\delta z')$$
$$-\Sigma m(\dot{x}\delta x+\dot{y}\delta y+\dot{z}\delta z), \quad . \quad . \quad (3)$$

where $H(=T+V)$ is the constant value of the energy in the free motion of the system, and $\tau\ (=t'-t)$ is the time of transit. In generalized co-ordinates this takes the form

$$\delta S=-H\delta\tau+p'_1\delta q'_1+p'_2\delta q'_2+\ldots$$
$$-p_1\delta q_1-p_2\delta q_2-\ldots \quad . \quad . \quad . \quad (4)$$

Now if we select any two arbitrary configurations as initial and final, it is evident that we can in general (by suitable initial velocities or impulses) start the system so that it will of itself pass from the first to the second in any prescribed time $\tau$. On this view of the matter, S will be a function of the initial and final co-ordinates ($q_1, q_2, \ldots$ and $q'_1, q'_2, \ldots$) and the time $\tau$, as independent variables. And we obtain at once from (4)

$$\left.\begin{aligned} p'_1&=\frac{\partial S}{\partial q'_1},\quad p'_2=\frac{\partial S}{\partial q'_2},\ \ldots,\\ p_1&=-\frac{\partial S}{\partial q_1},\quad p_2=-\frac{\partial S}{\partial q_2},\ \ldots,\end{aligned}\right\} \quad . \quad . \quad . \quad (5)$$

and
$$H=-\frac{\partial S}{\partial\tau}. \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (6)$$

S is called by Hamilton the *principal function;* if its general form for any system can be found, the preceding equations suffice to determine the motion resulting from any given conditions. If we substitute the values of $p_1$, $p_2$, ... and H from (5) and (6) in the expression for the kinetic energy in the form T' (see § 1), the equation

$$T'+V=H \quad . \quad . \quad . \quad . \quad . \quad (7)$$

becomes a partial differential equation to be satisfied by S. It has been shown by Jacobi that the dynamical problem resolves itself into obtaining a "complete" solution of this equation, involving $n+1$ arbitrary constants. This aspect of the subject, as a problem in partial differential equations, has received great attention at the hands of mathematicians, but must be passed over here.

There is a similar theory for the function

**Characteristic function.**

$$A=2\int Tdt=S+H\tau \quad . \quad . \quad . \quad . \quad (8)$$

It follows from (4) that

$$\delta A=\tau\delta H+p'_1\delta q'_1+p'_2\delta q'_2+\ldots$$
$$-p_1\delta q_1-p_2\delta q_2-\ldots \quad . \quad . \quad . \quad (9)$$

Selecting, as before, any two arbitrary configurations, it is in general possible to start the system from one of these, with a prescribed value of the total energy H, so that it shall pass through the other. Hence, regarding A as a function of the initial and final co-ordinates and the energy, we find

$$\left.\begin{aligned} p'_1&=\frac{\partial A}{\partial q'_1},\quad p'_2=\frac{\partial A}{\partial q'_2},\ \ldots,\\ p_1&=-\frac{\partial A}{\partial q_1},\quad p_2=-\frac{\partial A}{\partial q_2},\ \ldots,\end{aligned}\right\} \quad . \quad . \quad (10)$$

and
$$\tau=\frac{\partial A}{\partial H}. \quad . \quad . \quad . \quad . \quad . \quad (11)$$

A is called by Hamilton the *characteristic function;* it represents, of course, the "action" of the system in the free motion (with prescribed energy) between the two configurations. Like S, it satisfies a partial differential equation, obtained by substitution from (10) in (7). Some illustrations of the theory, for the case of a single particle, are given under MECHANICS (*Ency. Brit.* vol. xv. pp. 724–25).

The preceding theorems are easily adapted to the case of cyclic systems. We have only to write

$$S=\int_t^{t'}(\Theta-V)dt=\int_t^{t'}(T-\kappa\dot{\chi}-\kappa'\dot{\chi}'-\ldots-V)dt \quad . \quad (12)$$

in place of (1), and

$$A=\int(2T-\kappa\dot{\chi}-\kappa'\dot{\chi}-\ldots)dt, \quad . \quad . \quad . \quad (13)$$

in place of (8); cf. § 7 *ad fin.* It is understood, of course, that in (12) S is regarded as a function of the initial and final values of the palpable co-ordinates $q_1, q_2, \ldots q_m$, and of the time of transit $\tau$, the cyclic momenta being invariable. Similarly in (13), A is regarded as a function of the initial and final values of $q_1, q_2, \ldots q_m$, and of the total energy H, with the cyclic momenta invariable. It will be found that the forms of (4) and (9) will be conserved, provided the variations $\delta q_1$, $\delta q_2$, ... be understood to refer to the palpable co-ordinates alone. It follows that the equations (5), (6), and (10), (11) will still hold under the new meanings of the symbols.

*Reciprocal Properties of Direct and Reversed Motions.*

§ 9. We may employ Hamilton's principal function to prove a very remarkable formula connecting any *two* slightly disturbed natural motions of the system. If we use the symbols $\delta$ and $\Delta$ to denote the corresponding variations, the theorem is

**Lagrange's formula.**

$$\frac{d}{dt}\Sigma(\delta p_r.\Delta q_r-\Delta p_r.\delta q_r)=0\,; \quad . \quad . \quad . \quad (1)$$

or, integrating from $t$ to $t'$,

$$\Sigma(\delta p'_r.\Delta q'_r-\Delta p'_r.\delta q'_r)=\Sigma(\delta p_r.\Delta q_r-\Delta p_r.\delta q_r). \quad . \quad (2)$$

If for shortness we write

$$(r,\ s)=\frac{\partial^2 S}{\partial q_r\partial q_s},\quad (r,\ s')=\frac{\partial^2 S}{\partial q_r\partial q'_s}, \quad . \quad . \quad (3)$$

we have

$$\delta p_r=-\Sigma_s(r,\ s)\delta q_s-\Sigma_s(r,\ s')\delta q'_s \quad . \quad . \quad (4),$$

with a similar expression for $\Delta p_r$. Hence the right-hand side of (2) becomes

$$-\Sigma_r\{\Sigma_s(r,\ s)\delta q_s+\Sigma_s(r,\ s')\delta q'_s\}\Delta q_r+\Sigma_r\{\Sigma_s(r,\ s)\Delta q_s+\Sigma_s(r,\ s')\Delta q'_s\}\delta q_r$$
$$=\Sigma_r\Sigma_s(r,\ s')\{\delta q_r.\Delta q'_s-\Delta q_r.\delta q'_s\} \quad . \quad (5)$$

The same value is obtained in like manner for the expression on the left hand of (2); hence the theorem, which, in the form (1), is due to Lagrange, and was employed by him as the basis of his method of treating the dynamical theory of *Variation of Arbitrary Constants.*

The formula (2) leads at once to some remarkable reciprocal relations which were first expressed, in their complete form, by Helmholtz. Consider any natural motion of a conservative system between two configurations O and O′ through which it passes at times $t$ and $t'$ respectively, and let $t'-t=\tau$. As the system is passing through O let a small impulse $\delta p_r$ be given to it, and let the consequent alteration in the co-ordinate $q_s$ after the time $\tau$ be $\delta q'_s$. Next consider the *reversed* motion of the system, in which it would, if undisturbed, pass from O′ to O in the same time $\tau$. Let a small impulse $\delta p'_s$ be applied as the system is passing through O′, and let the consequent change in the co-ordinate $q_r$ after a time $\tau$ be $\delta q_r$. Helmholtz's first theorem is to the effect that

**Helmholtz's reciprocal theorems.**

$$\delta q_r : \delta p'_s=\delta q'_s : \delta p_r. \quad . \quad . \quad . \quad . \quad (6)$$

To prove this, suppose, in (2), that all the $\delta q$ vanish, and likewise all the $\delta p$ with the exception of $\delta p_r$. Further, suppose all the $\Delta q'$ to vanish, and likewise all the $\Delta p'$ except $\Delta p'_s$, the formula then gives

$$\delta p_r.\Delta q_r=-\Delta p'_s.\delta q'_s, \quad . \quad . \quad . \quad (7)$$

which is equivalent to Helmholtz's result, since we may suppose the symbol $\Delta$ to refer to the reversed motion, provided we change the signs of the $\Delta p$. For example, in the most general motion of a top (§ 2), suppose that a small impulsive couple about the vertical produces after a time $\tau$ a change $\delta\theta$ in the inclination of the axis, the theorem asserts that in the reversed motion an equal impulsive couple in the plane of $\theta$ will produce after a time $\tau$ a change $\delta\psi$, in the azimuth of the axis, which is equal to $\delta\theta$. It is understood, of course, that the couples have no components (in the generalized sense) except of the types indicated; for instance, they may consist in each case of a force applied to the top at a point of the axis, and of the accompanying reaction at the pivot. Again, in the corpuscular theory of light let O, O′ be any two points on the axis of a symmetrical optical combination, and let V, V′ be the corresponding velocities of light. At O let a small impulse be applied perpen-

dicular to the axis so as to produce an angular deflection $\delta\theta$, and let $\beta'$ be the corresponding lateral deviation at O′. In like manner, in the reversed motion, let a small deflection $\delta\theta'$ at O′ produce a lateral deviation $\beta$ at O. The theorem (6) asserts that

$$\frac{\beta}{V'\delta\theta'}=\frac{\beta'}{V\delta\theta}, \quad . \quad . \quad . \quad . \quad . \quad (8)$$

or, in optical language, the "apparent distance" of O from O′ is to that of O′ from O in the ratio of the refractive indices at O′ and O respectively.

**Helmholtz's second reciprocal theorem.**

In the second reciprocal theorem of Helmholtz the configuration O is slightly varied by a change $\delta q_r$ in one of the co-ordinates, the momenta being all unaltered, and $\delta p'_s$ is the consequent variation in one of the momenta after time $\tau$. Similarly in the reversed motion a change $\delta q'_s$ produces after time $\tau$ a change of momentum $\delta p_r$. The theorem asserts that

$$\delta p'_s : \delta q_r = \delta p_r : \delta q'_s \quad . \quad . \quad . \quad . \quad . \quad (9)$$

This follows at once from (2) if we imagine all the $\delta p$ to vanish, and likewise all the $\delta q$ save $\delta q_r$, and if (further) we imagine all the $\Delta p'$ to vanish, and all the $\Delta q'$ save $\Delta q'_s$. Reverting to the optical illustration, if F, F′, be principal foci, we can infer that the convergence at F′ of a parallel beam from F is to the convergence at F of a parallel beam from F′ in the inverse ratio of the refractive indices at F′ and F. This is equivalent to Gauss's relation between the two principal focal lengths of an optical instrument. It may be obtained otherwise as a particular case of (8).

We have by no means exhausted the inferences to be drawn from Lagrange's formula. It may be noted that (6) includes as particular cases various important reciprocal relations in Optics and Acoustics formulated by Clausius, Helmholtz, Thomson and Tait, and Lord Rayleigh. In applying the theorem care must be taken that in the reversed motion the reversal is complete, and extends to every velocity in the system; in particular, in a cyclic system the cyclic motions must be imagined to be reversed with the rest. Conspicuous instances of the failure of the theorem through incomplete reversal are afforded by the propagation of sound in a wind and the propagation of light in a magnetic medium.

It may be worth while to point out, however, that there is no such limitation to the use of Lagrange's formula (1). In applying it to cyclic systems, it is convenient to introduce conditions already laid down, viz., that the co-ordinates $q_r$ are the palpable co-ordinates, and that the cyclic momenta are invariable. Special inferences can then be drawn as before, but the interpretation cannot be expressed so neatly owing to the non-reversibility of the motion.

Authorities.—The most important and most accessible early authorities are Lagrange, *Mécanique Analytique*, 1st ed., Paris, 1788, 2nd ed., Paris, 1811; Hamilton, "On a General Method in Dynamics," *Phil. Trans.*, 1834 and 1835; Jacobi, *Vorlesungen über Dynamik*, Berlin, 1866, reprinted in *Werke*, *Supp.-Bd.*, Berlin, 1884. An account of the extensive literature on the differential equations of dynamics and on the theory of variation of parameters is given by Cayley, "Report on Theoretical Dynamics," *Brit. Assn. Rep.*, 1857, *Mathematical Papers*, vol. iii., Cambridge, 1890. For the modern developments reference may be made to Thomson and Tait, *Natural Philosophy*, 1st ed., Oxford, 1867, 2nd ed., Cambridge, 1879; Lord Rayleigh, *Theory of Sound*, vol. i., 1st ed., London, 1877, 2nd ed., London, 1894; Routh, *Stability of Motion*, London, 1877, and *Rigid Dynamics*, 4th ed., London, 1884; Helmholtz, "Ueber die physikalische Bedeutung des Princips der kleinsten Action," *Crelle*, vol. c. 1886, reprinted (with other cognate papers) in *Wiss. Abh.* vol. iii., Leipzig, 1895; Larmor, "On Least Action," *Proc. Lond. Math. Soc.* vol. xv. 1884. As to the question of stability, reference may be made to Poincaré, "Sur l'équilibre d'une masse fluide animée d'un mouvement de rotation," *Acta Math.* vol. vii., 1885; Klein and Sommerfeld, *Theorie des Kreisels*, pts. 1, 2, Leipzig, 1897–98; Lioupanoff and Hadamard, *Liouville*, 5me série, vol. iii., 1897. A remarkable interpretation of various dynamical principles is given by Hertz in his posthumous work *Die Prinzipien der Mechanik*, Leipzig, 1894, of which an English translation appeared in 1900. (H. Lb.)

**Dynamo.**—Invented by Faraday in 1831, the dynamo ranks with the telegraph and telephone among the most striking achievements of science, and the material progress that marked the later years of the 19th century was in no small measure due to the practical application of these three electrical inventions. Since 1830 the simple model constructed by Faraday has been gradually developed into the dynamos of 5000 horse-power or more, which are constructed to meet the needs of large cities for electric lighting and power, and the machines in use are to be numbered, not by hundreds or thousands, but by hundreds of thousands. Yet the fundamental theory of the dynamo, as a machine for generating electromotive force, remains but little changed, and the advance since Faraday's time may, by comparison with his results, be regarded as a progressive improvement of the mechanical and electrical design leading to a fuller realization of the idea which was already present in his mind. His experiments on the induction of currents in a coil of wire during the approach or recession of a magnet led naturally to the explanation of induced electromotive force as caused by the linking or unlinking of magnetic lines of flux with an electric circuit. For the more definite case of the dynamo, however, we may, with Faraday, make the transition from line-linkage to the precisely equivalent conception of "*line-cutting*" as the source of E.M.F.—in other words, to the idea of electric conductors "cutting" or intersecting[1] the lines of flux in virtue of relative motion of the magnetic field and electric circuit. On 28th October 1831 Faraday mounted a copper disc so that it could be rotated edgewise between the poles of a permanent horse-shoe magnet. When so rotated, it cut the lines of flux which passed transversely through its upper half, and by means of two rubbing contacts, one on its periphery and the other on its spindle or axis, the circuit was closed through a galvanometer, which indicated the passage of a continuous current so long as the disc was rotated (Fig. 1). Thus by the invention of the first dynamo Faraday proved his idea that the E.M.F. induced through the interaction of a magnetic field and an electric circuit was due to the passage of a portion of the electric circuit *across* the lines of flux, or *vice versâ*, and so could be maintained if the cutting of the lines were made continuous.[2]

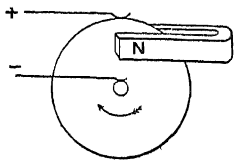

Fig. 1.

A dynamo, then, is a machine in which, by means of continuous relative motion, an electrical conductor or system of conductors forming part of a circuit is caused to cut the lines of a magnetic field or fields; the cutting of the magnetic flux induces an electromotive force in the conductors, and when the circuit is closed a current flows, whereby mechanical energy is converted into electrical energy.

Little practical use could be made of electrical energy so long as its only known sources were frictional machines and voltaic batteries. The cost of the materials for producing electrical currents on a large scale by chemical action was prohibitive, while the frictional machine only yielded very small currents at extremely high potentials. In the dynamo, on the other hand, electrical energy in a convenient form could be cheaply and easily obtained by mechanical means, and with its invention the application of electricity to a wide range of commercial purposes became economically possible. As a converter of energy from one form to another it is only surpassed in efficiency by another electrical appliance, namely, the transformer (see Transformers). In this there is merely conversion of electrical energy at a high potential into electrical energy at a low potential, or *vice versâ*, but in the dynamo the mechanical energy which must be applied to maintain the relative movement of magnetic field and conductor is absorbed, and reappears in an electrical form. A true transformation takes place, and the proportion which the rate of delivery of electrical energy bears to the power absorbed, or in other words the *efficiency*, is the more remarkable. The useful return or "output" at the terminals of a large machine may amount to as much as 95 per cent. of the mechanical energy which forms the "input." Since it needs some prime mover to drive it, the dynamo has not made any direct addition to our sources of energy, and does not therefore rank with the primary battery or oil engine, or even the steam engine, all of which draw their energy more immediately from

nature. Yet by the aid of the dynamo the power to be derived from waterfalls can be economically and conveniently converted into an electrical form and brought to the neighbouring factory or distant town, to be there reconverted by motors into mechanical power. Over any but very short distances energy is most easily transmitted when it is in an electrical form, and turbine-driven dynamos are very largely and successfully employed for such transmission. Thus by conducing to the utilization of water-power which may previously have had but little value owing to its disadvantageous situation, the dynamo may almost be said to have added another to our available natural resources.

The two essential parts of the dynamo, as required by its definition, may be illustrated by the original disc machine of Faraday. They are (1) the *iron magnet*, between the poles of which a magnetic field exists, and (2) the *electrical conductors*, represented by the rotating copper disc. The sector of the disc [1] cutting the lines of the field forms part of a closed electric circuit, and has an E.M.F. induced in it, by reason of which it is no longer simply a conductor, but may be called an "*inductor*." In its more highly developed form the simple copper disc becomes a system of many inductors so inter-connected as to add up their several E.M.F.'s. Since these inductors are very commonly mounted on an iron structure, which may be likened to the keeper or "armature" of a magnet rotating between its poles, the term "*armature*" has been extended to cover not only the iron core, but also the wires on it, and is often applied to the copper conductors themselves even when there is no iron core. In the dynamo of Faraday it is the "armature" which is rotated, and such is usually the case; sometimes, however, the magnet, or a portion of it, is rotated. It is in fact immaterial to the action whether the one or the other is moved, or both, so long as their relative motion causes the armature inductors to cut the magnetic flux. As to the ultimate reason why an E.M.F. should be thereby induced, physical science cannot as yet yield any surer knowledge than in the days of Faraday.[2] For the engineer, the simple fact is sufficient that the E.M.F. of the dynamo is due to the cutting of the magnetic flux by the inductors, and, further, is proportional to the rate at which the lines are cut.[3]

The equation of the *electromotive force* which is required in order to render this statement quantitative must contain three factors, namely, the density of the flux in the air-gap through which the inductors move, the length of the inductors, and the speed of their movement. For given values of the first and third factors and a single straight inductor moved parallel to itself through a uniform field, the maximum rate of cutting is evidently obtained when the three directions of the lines, the armature inductor, and the relative motion are respectively at right angles to each other, as shown by the three co-ordinate axes of Fig. 2. Under these circumstances the E.M.F. of the inductor is

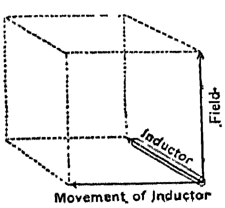

Fig. 2.

$$E = B_g LV \times 10^{-8} \text{ volts}, \quad . \quad . \quad . \quad . \quad \text{(I.)}$$

where $B_g$ is the density [4] of the lines of flux per square centimetre in the air-gap, L is the active length of the inductor within the field in centimetres, and V is the velocity of movement in centimetres per second. Further, the direction in which the E.M.F. has the above maximum value is along the length of the inductor, its "sense" being determined by the relative directions of the field and movement.[5]

The second fundamental equation of the dynamo brings to light its mechanical side, and rests on Oerstedt's discovery of the interaction of a magnetic field and an electric current. If a straight electric conductor carrying a current be so placed in a magnetic field that its length is not parallel to the direction of the lines of flux, it is acted on by a force which, if not balanced by an equal and opposite force, will cause the conductor to move in a definite direction; or if the conductor is fixed and the magnet be unconstrained, the latter will itself move in the opposite direction. Now in the dynamo the inductors are placed so that their length may be as nearly as possible at right angles to the field; hence when they are rotated and an electric current begins to flow under the E.M.F. which they induce, a mutual force at once arises between the copper conductors and the magnet, and the direction of this force must by Lenz's law [6] be opposed to the direction of the movement. Thus as soon as the disc of Fig. 1 is rotated and its circuit is closed, it experiences a mechanical pull or drag, which must be overcome by the force applied to rotate it. While the magnet must be firmly held so as to remain stationary, the mechanical construction of the armature must be such that its inductors can be forcibly driven through the magnetic field against the mutual pull. The law of electrodynamic action requires its *equation of mechanical force*, just as the law of electromagnetic induction requires the equation of electromotive force, and it may be expressed in analogous terms. If a conductor of length L cm., carrying a current C amperes, is immersed in a field of uniform density $B_g$, and the length of the conductor is at right angles to the direction of the lines, it is acted on by a force

$$F = B_g LC \times 10^{-1} \text{ dynes}, \quad . \quad . \quad . \quad . \quad \text{(II.)}$$

and the direction of this force is at right angles to the conductor and to the field. The rate at which electrical energy is developed, when this force is overcome by moving the inductor as a dynamo through the field, is $EC = B_g LVC \times 10^{-8}$ watts, whence the equality of the mechanical power absorbed and the electrical power developed (as required by the law of the conservation of energy) is easily established. The whole of this power is not, however, available at the terminals of the machine; if $R_a$ be the resistance of the armature in ohms, the passage of the current $C_a$ through the armature inductors causes a loss of pressure of $C_a R_a$ volts, and a corresponding loss of energy in the armature at the rate of $C_a^2 R_a$ watts. As the resistance of the external circuit $R_e$ is lowered, the current $C = \dfrac{E_a}{R_e + R_a}$ is increased, but at the same time the external voltage at the terminals of the machine is decreased, until a maximum output is reached, when the loss of volts over the internal resistance is equal to the loss of volts over the external resistance. The increase of the current is, however, accompanied by a progressive increase in the loss of energy over the armature, and as this is expended in heating the armature conductors, their temperature may rise so much as to destroy the insulating materials with which they are covered. Hence the temperature which the machine may be permitted to attain in its working is of great importance in determining its output, the current which forms one factor therein being primarily limited by the heating of the armature wires. The lower the resistance of the armature, the less the rise of its temperature for a given current flowing through it; and the reason for

the almost universal adoption of copper as the material for the armature inductors is now seen to lie in its high conductivity.[1]

Since the voltage of the dynamo is the second factor to which its output is proportional, the conditions which render the induced E.M.F. a maximum must evidently be reproduced as far as possible in practice, if the best use is to be made of a given mass of iron and copper. The first problem, therefore, in the construction of the dynamo is the disposition of the inductors and field in such a manner that the three directions of field, inductors, and movement are at right angles to one another, and so that the relative motion is continuous. Reciprocating motion, such as would be obtained by direct attachment of the inductors to the piston of a steam-engine, has been successfully employed only in the special case of an "oscillator"[2] producing a small current very rapidly changing in direction. *Rotary motion* is therefore universally adopted, and with this two distinct cases arise. Either (A) the length of the inductor is parallel to the axis of rotation, or (B) it is at right angles to it. A single inductor cannot, however, be made to give more than a few volts, and hence it is necessary to use several inductors, and to add up their E.M.F.'s by connecting them in series. Two methods of effecting this may be distinguished, and as each may be applied both to case (A) and to case (B), four types of armatures result therefrom.

(A). If an inductor is rotated in a rectangular gap formed in a horse-shoe magnet by two pole-pieces having plane faces opposed to each other, as in Fig. 3, not only is the density of the flux in the gap between the poles small, but the direction of movement is not always at right angles to the direction of the lines. Starting from the position of the inductor when it is mid-way between the pole-tips, its rate of line-cutting will increase to a maximum as it passes under the centre of a pole-face, and will then decrease to zero. As it crosses a line drawn symmetrically through the gaps between the poles, the direction of the E.M.F. along its length is reversed, since its motion relatively to the direction of the field is reversed. If the ends of the inductor are electrically connected to two collecting rings fixed on, but insulated from, the shaft, two stationary brushes *b b* can be pressed so as to make rubbing contact with the rings, and an external circuit may be connected to the brushes, which then form the "terminals" of the machine; the alternating E.M.F. set up in the inductor will cause an alternating current to flow through the external circuit, and the simplest form of *alternator* is obtained. If the field cut by the inductor is of uniform density, and all the lines pass straight across from one pole to the other (both of which assumptions are approximately correct), a curve connecting the instantaneous values of the E.M.F., as ordinates, with time or degrees of revolution, as abscissæ (as shown at the foot of Fig. 3), will be sinusoidal when the speed of rotation is uniform.

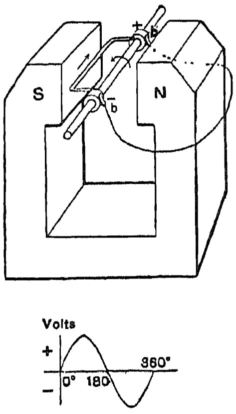

Fig. 3.

If, however, the inductor is mounted on an iron cylinder (Fig. 4),[3] a sufficient margin being allowed for mechanical clearance between the inductor and the poles, not only will the reluctance of the magnetic circuit be reduced, and the total flux and its density in the air-gap $B_g$ be thereby increased, but the path of the lines will become nearly radial, except at the "fringe" near the edges of the pole-tips, and hence the relative directions of the movement and lines will be continuously at right angles. The shape of the E.M.F. curve will then be as shown in Fig. 4—flat-topped, with rounded corners rapidly sloping down to the zero line.

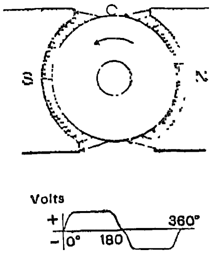

Fig. 4.

With the addition of a number of similar inductors arranged along the length of the armature core parallel to the first, the question arises of their connexion, in order to add their E.M.F.'s. Since the E.M.F.'s generated by the inductors under the one pole-piece are opposite in direction to those induced under the other pole-piece as viewed from one end of the armature (Fig. 5, where the dotted and crossed wires indicate E.M.F.'s directed towards and away from the observer), two distinct methods are possible by which two or more inductors can be joined in series.

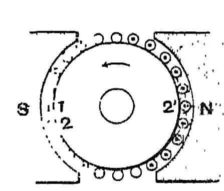

Fig. 5.

(1) The first, or *ring*-winding, was invented by Dr Antonio Pacinotti of Florence[4] in 1860, and was subsequently and independently reintroduced in 1870[5] by the Belgian electrician, Zénobe Théophile Gramme, whence it is also frequently called the "Gramme" winding. By this method the farther end of inductor 1 (Fig. 5) is joined to the near end of inductor 2; this latter lies next to it on the surface of the core or immediately above it, so that both are simultaneously under the same pole-piece. For this connexion to be possible, the armature core must be a hollow cylinder, supported from the shaft on an open non-magnetic spider or hub, between the arms of which there is room for the internal wire completing the loop (Fig. 6). The end of one complete loop or turn embracing one side of the armature core thus forms the starting-point for another loop, and the process can be continued if required to form a coil of two or more turns. In the ring armature the iron core serves the double purpose of conducting the lines across from one pole to the other, and also of shielding from the magnetic flux the hollow interior through which the connecting wires pass. Any lines which leak across the central space are cut by the internal wires, and the direction of cutting is such that the E.M.F. caused thereby opposes the E.M.F. due to the inductors proper on the external surface. If, however, the section of iron in the core

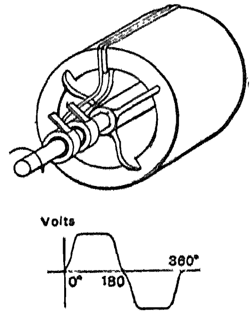

Fig. 6.

[1] Faraday, *Exp. Res.*, series ii. § 6, pars. 211, 213; series xxviii. § 34, par. 3152.

[2] Invented by Nikola Tesla (*Elec. Eng.* vol. xiii. p. 83. Cp. Brit. Pat., Spec. Nos. 2801 and 2812, 1894). Several early inventors, *e.g.*, Dal Negro in 1832 (*Phil. Mag.*, third series, vol. i. p. 45), adopted reciprocating or oscillatory motion, and this was again tried by Edison in 1878.

[3] The advantage to be obtained by making the poles closely embrace the armature core was first realized by Dr Werner von Siemens of Berlin in his "shuttle-wound" armature (Brit. Pat., No. 2107, 1856).

[4] *Nuovo Cimento*, 19, p. 378, 1865. Elias of Amsterdam is by some credited with having used ring winding on a motor even earlier than 1860.

[5] Brit. Pat., No. 1668, 1870. *Comptes Rendus*, 73, p. 175, 1871.

be correctly proportioned, the number of lines which cross the interior will bear but a small ratio to those which pass entirely through the iron, and the counter E.M.F. of the internal wires will become very small; they may then be regarded simply as connectors for joining the external inductors in series.

(2) The second or *drum* method was used in the original "shuttle-wound" armatures invented by Dr Werner von Siemens in 1856, and is still known as the "Siemens" winding. The farther end of inductor 1 (Fig. 5) is joined by a connecting wire to the farther end of another inductor 2′ situated nearly diametrically opposite on the other side of the core and under the opposite pole-piece. The near end of the complete loop or turn is then brought across the end of the core, and can be used as the starting-point for another loop beginning with inductor 2, which is situated by the side of the first inductor. The iron core may now be solid from the surface to the shaft, since no connecting wires are brought through the centre, and each loop embraces the entire armature core (Fig. 7). By the formation of two loops in the ring armature and of the single loop in the drum armature, two inductors are placed in series; the curve of instantaneous E.M.F. is therefore similar in shape to that of the single inductor (Fig. 4), but with its ordinates raised throughout to double their former height, as shown at the foot of Fig. 6.

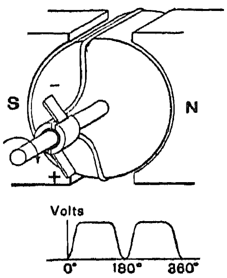

Fig 7

Next, if the free ends of either the ring or drum loops, instead of being connected to two collecting rings, are attached to the two halves of a split-ring insulated from the shaft (as shown in Fig. 7 in connexion with a drum armature), and the stationary brushes are so set relatively to the loops that they pass over from the one half of the split-ring to the other half at the moment when the loops are passing the centre of the interpolar gap, and so are giving little or no E.M.F., each brush will always remain either positive or negative. The current in the external circuit attached to the brushes will then have a constant direction, although the E.M.F. in the inductors still remains alternating; the curve of E.M.F. obtained at the brushes is thus (as in Fig. 7) entirely above the zero line. The first dynamo of Pixii,[1] which immediately followed Faraday's discovery, gave an alternating current, but in 1832[2] the alternator was converted into a machine giving a *unidirected current* by the substitution of a rudimentary "commutator" in place of mercury collecting cups.

On passing to case (B) we are at once reminded of the original dynamo of Faraday, yet though the disc of Fig. 1 is in reality a single inductor whose plane of movement is at right angles to its axis of rotation, it has the peculiarity that the E.M.F. generated is always in the same direction along the inductor's length; it thus represents a class of machines which are distinguished by the somewhat misleading name of "unipolar" dynamos. In this special form the (B) principle of arrangement is seldom employed, since it is difficult to add other inductors in order to increase the E.M.F. If, however, the magnetic circuit be interrupted by another air-gap (Fig. 8), a single inductor can be arranged to cut the flux twice in each revolution in different directions as it passes through the two air-gaps. The E.M.F. which is now produced in the inductor will be first radially outwards, and then inwards towards the centre, *i.e.*, it alternates in direction just as in case (A). It then becomes possible to employ a number of inductors (Fig. 9), and to add together their E.M.F.'s in series by methods which are analogous to the ring and drum winding already discussed under case (A), and which yield the third and fourth types of armature.

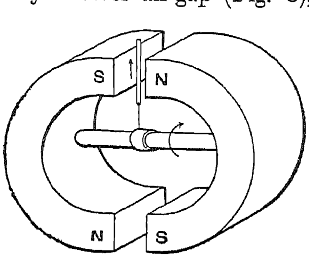

Fig. 8

(3) By the *discoidal* or flat-ring method (Fig. 10) an inductor 1 is joined to its next neighbour 2, and for this to be possible it is again necessary that there should be an iron core (as A in Fig. 9) to convey the lines from one pole to the other, and at the same time to shield the connecting wires, so that they may not themselves cut the field. A second magnet M′ (shown dotted in Fig. 10) can now be arranged on the opposite side of the armature core to the first magnet M, with poles of the same sign facing each other. The greater portion of the length of the wires which previously served merely as conductors can then also be rendered usefully inductive, the inactive connectors being simply the wires joining the two sides of each loop.[3] The armature thus takes the form of a flat ring (Fig. 10), and is analogous to a ring armature in which a second pair of poles is introduced into the centre of the core, each of the same sign as the external pole which it faces.

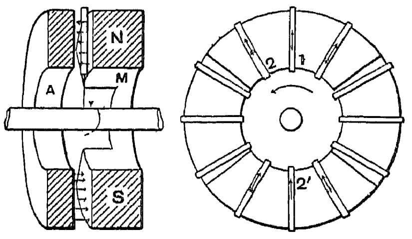

Fig. 9.

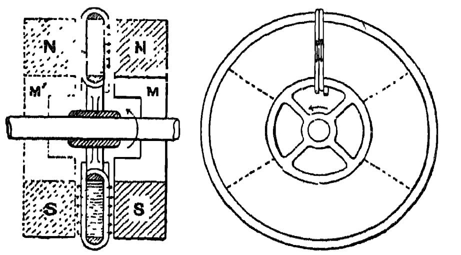

Fig. 10.

(4) The fourth or *disc* winding was in principle em-

[1] *Ann. Chim. Phys.* vol. l. p. 322.

[2] *Ann. Chim. Phys.* vol. li. p. 76. Since in Pixii's machine the armature was stationary, while both magnet and commutator rotated, four brushes were used, and the arrangement was not so simple as the split-ring described above, although the result was the same. Saxton's machine (1833) and Clarke's machine (1835, see Sturgeon's *Annals of Electricity*, vol. i. p. 145) were similar to one another in that a unidirected current was obtained by utilizing every alternate half-wave of E.M.F., but the former still employed mercury collecting cups, while the latter employed metal brushes. Sturgeon in 1835 followed Pixii in utilizing the entire wave of E.M.F., and abandoned the mercury cups in favour of metal brushes pressing on four semi-circular discs (*Scientific Researches*, p. 252). The simple split-ring is described by Wheatstone and Cooke in their Patent No. 8345, 1840.

[3] The advantage originally claimed for the discoidal-ring machine, namely, that the rim of the armature could also be utilized by joining the opposite poles, and that so the inactive length of the wire was considerably reduced as compared with the longitudinally-wound ring (Schuckert, Brit. Pat., No. 4464, 1877), has proved somewhat illusory, owing to the difficulty of avoiding eddy-currents in the core when the flux enters it in two directions at right angles to each other, from the sides and from the overarching pole-piece respectively.

ployed in many of the earliest machines, and especially in alternators, but has not met with much favour for continuous-current dynamos. In this method the outer end of inductor 1 is joined, by a connecting wire passing round the periphery, to the outer end of another inductor 2′ situated nearly diametrically opposite under the other pole (Fig. 9). No iron core is now required; the two opposite poles can be brought close together, leaving but a short path for the lines in the air-gap, and any mechanical support on which the wires are wound may be non-magnetic. By bringing the inner end of inductor 2′ along the inside periphery (Fig. 11), a loop is formed, which may be again repeated. If the ends of the loops

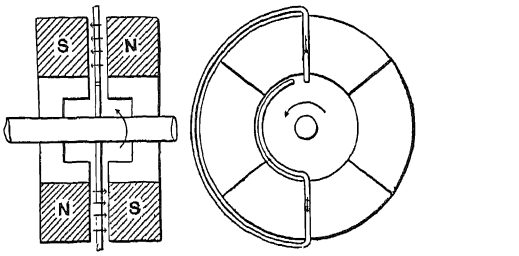

Fig 11

thus formed by either method (3) or (4) are connected to a pair of collecting rings, a simple discoidal-ring or disc alternator is obtained, while if they are connected to a split-ring the current may be commuted, and the dynamo gives a unidirected E.M.F. and current in the external circuit. It is therefore true to say that in almost all dynamos which are used in practice, whether they supply an alternating or a continuous current to the external circuit, the E.M.F. and current in the inductors themselves are alternating.

The addition of new loops leads to a coil of many turns, and thence to a number of coils. If the several new loops are wound over each other in the ring, drum, and discoidal-ring armatures, or by the side of each other in the disc, the depth of the wires in the air-gap would necessitate such a long distance between the pole-piece and the armature core, or between the opposing poles of the disc, that it would be difficult to obtain a sufficiently strong magnetic field. The additional loops must be wound side by side in the first three cases, or on the top of each other in the disc armature. The coil thus has a certain width along the face of the poles, and the effect of such width must be considered in its relation to the width of the poles. The *pitch-line* being defined as a circle drawn through the middle of the length of the inductors, or, in other words, as the mean path traversed by them in their rotation, it is convenient to refer the widths of pole, interpolar gap, and coil to the *pitch*, or the distance measured along the pitch-line from the centre of one pole to the centre of a neighbouring pole of opposite sign. In the ring armature, if the E.M.F.'s induced by the turns in any one coil are to be added in series, they must be in the same direction along the inductors. A ring core entirely overwound with one coil in a continuous helix would give no E.M.F. at the ends; but when the coil is divided into two halves, these may, by means of appropriate connexions, be placed either in series or in parallel, and each half will at any instant give the same E.M.F. The ring armature must therefore be divided into at least two coils, and it is then evident that if the width of each coil exceeds the width of the interpolar gap, the loops will for some portion of one revolution be moving at the same time under two poles of opposite sign, and consequently *differential action* will be set up, by which one part of the coil will be inducing an E.M.F. opposed in direction to that of the rest. If this disadvantageous action is to be avoided, either the width of the coil or the width of the pole, or both, must be reduced until the coil is no wider than the interpolar gap. If the coil be wide, the poles must be narrow, so that with a given density the number of lines in a field will be very small; while, on the other hand, if the coil be narrow and the pole wide, the flux of one field may be large, but the number of inductors in the coil must be small.

If the poles of the alternator are arranged in two separate circles (as in Fig. 43), all the N poles forming one crown and all the S poles another crown, the width of the poles may be equal to the pitch; but if they occur alternately, first a N pole and then a S pole round the same circle, their width must be less than equal to the pitch in order to avoid an excessive amount of magnetic leakage between the adjacent pole-edges. Considerations of the inductance of the armature and of its heating in turn limit the feasible width of winding in the armature coils. A compromise has therefore to be made, and experience shows that in practice the best combined use of an armature core and field-magnet of given size is made if the width of the poles of alternate sign is approximately half the pitch, and the width of the ring coil is equal to the width of a pole. The two-pole machine will then have two coils,

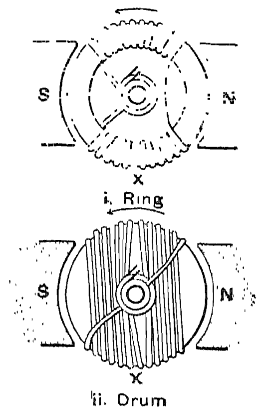

Fig. 12.

and the armature core will be only half covered with winding (Fig. 12 i.). The same considerations govern the best width of a drum coil. If the core be entirely overwound (as in Fig. 12 ii., if the blank portions of the core were covered with loops of continually diminishing size), the arrangement is the equivalent of the ring armature with two coils in series, each of width equal to the pitch. The single coil of the bipolar drum may equally well be divided into two coils, the largest loop of each half having a width equal to the pitch; and the two coils so formed may be connected either in series or in parallel. Again, however, if there is to be no differential action, opposite sides of one coil must never be moving under the same pole, and the innermost or smallest loop must not be less in width than the pole-face. The best proportions are obtained if the width of the inner loop and the width of the field are each approximately equal to half the pitch (Fig. 12 ii.). The same reasoning can easily be applied to the discoidal ring and disc machines, and will lead to like results.

If the bipolar armatures of Fig. 12 are imagined to be cut through to the centre from any point X and opened out, it is evident that any number of pairs of coils similarly spaced to the original pair may be inserted without in any way affecting the action, save to increase the periodicity of the alternating E.M.F.; an equal number of pairs of poles may then also be added, with a corresponding increase in the total E.M.F., and the *multipolar alternators*[1] of Fig. 13 are obtained. As the wires of a coil pass gradually into or out of action, the total E.M.F. of the coil, being the sum of the E.M.F.'s in the separate inductors, rises or falls gradually, the maximum value being reached when the coil is immediately under a pole in the ring armature, or when the side of a coil is under a pole in the drum and disc machines. When the coil enters under the next pole of opposite sign, the gradual rise and fall are again repeated, but the E.M.F. is in the opposite direction. Thus the passage of a coil through two magnetic fields of opposite direction yields a complete wave of E.M.F. such as is shown in Fig. 6, and the time in seconds taken by the E.M.F. or current to pass through such a complete cycle is the "period" of the alternator. The number of complete periods through which the E.M.F. or current passes per second is called the *periodicity* or *frequency*, and in the bipolar alternator is equal to the number of revolutions per second. In the multipolar alternators of Fig. 13 the coils may be arranged either in series or in parallel, since their phases are all alike; the periodicity of the multipolar alternator is with either arrangement equal to the number of pairs of fields through which a coil passes in one second, so that in general the periodicity$=\frac{N}{60}\times p$, where N = the number of revolutions per

[1] The first use of a number of pairs of coils and an equal number of pairs of poles was due to Stöhrer of Leipzig, *Pogg. Ann.* lxi. 417, 1844.

minute, and $p$ = the number of pairs of fields. In the ring and drum alternators, $p$ is also the number of pairs of poles, but in the discoidal ring and the disc types the pairs of poles must be reckoned on one side only, since each pair of poles facing each other on opposite sides of the armature only corresponds to a single field.

The above reasoning has, so far, led us in all cases to as many coils as there are fields and an armature core only half covered with winding, and such is the form taken by the *single-phase alternator*. But since only one-half of the armature core is utilized, an entirely distinct but similar set of coils may be wound to form a second armature circuit between the coils of the first circuit. The phase of this second circuit will differ by a quarter of a period from that of the first, and it may either be used to feed an entirely separate external circuit, possibly at a different pressure, or, if it be composed of the same number of inductors and therefore gives the same pressure, it may be inter-connected with the first circuit to form a *quarter-phase alternator*. By an extension of the same process, if the width of winding in each ring coil be reduced to

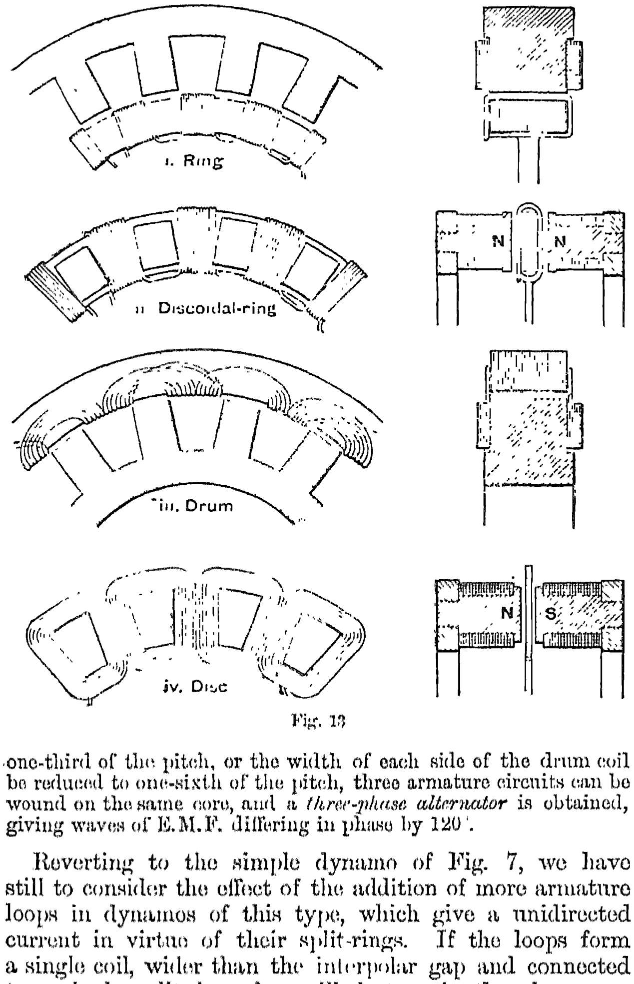

Fig. 13

one-third of the pitch, or the width of each side of the drum coil be reduced to one-sixth of the pitch, three armature circuits can be wound on the same core, and a *three-phase alternator* is obtained, giving waves of E.M.F. differing in phase by 120°.

Reverting to the simple dynamo of Fig. 7, we have still to consider the effect of the addition of more armature loops in dynamos of this type, which give a unidirected current in virtue of their split-rings. If the loops form a single coil, wider than the interpolar gap and connected to a single split-ring, they will, just as in the alternator, act differentially against one another during part of a revolution. Hence the coil must be more or less concentrated into a narrow band. Such an arrangement in the case of drum winding gives the H-form "shuttle" armature invented by Dr Werner von Siemens. Although its E.M.F. has a much higher maximum value than that of the curve of Fig. 7, it still periodically varies during each revolution, and so gives a pulsating current. To avoid the pulsation, recourse must be had to a new principle peculiar to the *closed-coil continuous-current machine*, which is by far the most largely used of all dynamos. Since a second coil placed at right angles to the original coil will yield a wave of E.M.F. of which the crests will coincide with the hollows of the first wave, the E.M.F.'s of the two coils when in series will supplement each other, and the fluctuations of the resultant curve will be greatly reduced, although its maximum may be no higher. Instead, therefore, of concentrating the new loops into a narrow coil, as in the case of the alternator, the opposite course must be pursued, and the loops be divided between several coils equally spaced round the armature. Given two coils at right angles and with their split-rings displaced through a corresponding angle of 90°, they may be connected in series by joining one brush to the opposite brush of the second coil, the external circuit being applied to the two remaining brushes.[1] The same arrangement may again be repeated with another pair of coils in parallel with the first, and we thus obtain Fig. 14 with four split-rings,

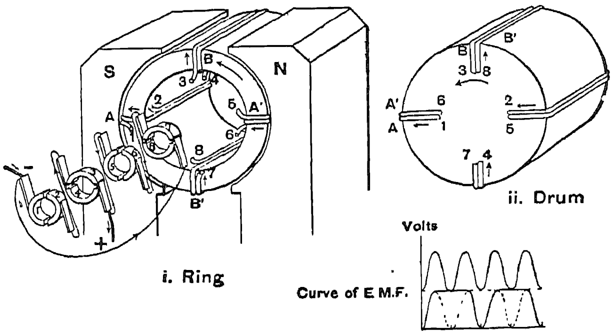

Fig. 14.

their connexions to the loops being marked by corresponding numerals; the four coils will give the same E.M.F. as the two, but they will be jointly capable of carrying twice the current, owing to their division into two parallel circuits. Now, since the effect of joining brush 2 across to brush 3 is virtually to connect the end of coil A with the beginning of coil B, and so on until they are closed upon themselves in a continuous helix, the four split-rings may be replaced by the simpler arrangement of Fig. 15, consisting of four segmental portions of a cylinder, insulated from one another and from the shaft, and requiring only two brushes, which form the terminals of the external circuit. Each sector replaces a pair of halves of adjacent split-rings, in the order of sequence, 2 and 3, 4 and 5, 6 and 7, 8 and 1. The function of this structure[2] being not merely to collect the current, but to commute its direction in any coil as it passes through the interpolar gap, it is known as the *commutator*. Each coil is successively short-circuited, as a brush bridges over the insulation between the two sectors which terminate it; and the brushes must be so set that the period of short-circuit takes place when the coil is generating little or no E.M.F., *i.e.*, when it is moving through the zone between the pole-tips. The effect of the four coils in reducing the percentage fluctuation of the E.M.F. is very marked, as shown at the foot of Fig. 14 (where the upper curve is the resultant obtained by adding together the separate curves of coils A and B), and the levelling process may evidently be carried still further by the insertion of more coils and more corresponding sectors in the commutator, until the whole armature is covered with winding. For example, Fig. 16 shows a ring and a drum armature, each with eight coils and eight commutator sectors; their resultant curve, on the assumption that a single inductor

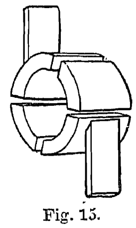

Fig. 15.

[1] Such was the arrangement of Wheatstone's machine (Brit. Pat., No. 9022) of 1841, which was the first to give a more nearly *continuous* current, the number of sections and split-rings being five.

[2] Its development from the split-ring was due to Pacinotti and Gramme (Brit. Pat., No. 1668, 1870) in connexion with their ring armatures.

gives the flat-topped curve of Fig. 4, will be the upper wavy line of E.M.F. obtained by adding together two of the resultant curves of Fig. 14, with a relative displacement of 45°. The amount of fluctuation for a given number of commutator sectors depends upon the shape of the curve of E.M.F. yielded by the separate small sections of the armature winding; the greater the polar arc, the less the fluctuation. In practice, with a polar arc equal to about 0·75 of the pitch, any number of sectors over 32 yields an E.M.F. which is sensibly constant throughout one or any number of revolutions. If the armatures of Fig. 16 be imagined to be cut across to the centre from any point such as X and opened out, as was also done in the case of alternators, any number of pairs of poles, with a corresponding increase in the number of inductors, may be added, and multipolar continuous-current dynamos are obtained. But whereas in the alternator there may in each phase be only one circuit through the armature, in the continuous-current closed-coil armature there can never be less than two parallel circuits, while if there are more than two, there must be as many as there are poles.[1] The two conditions coincide in the simple bipolar armature, since it has two parallel paths through the armature, or as many as there are poles.

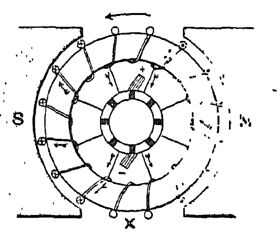

Fig. 16A

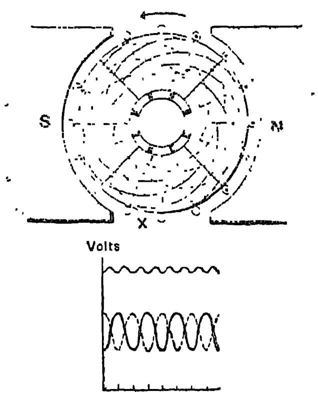

Fig. 16B.

The fundamental *electromotive force equation* can now be given a more definite form, suitable for both the continuous-current dynamo and the alternator. Let $Z_a$ = the number of C.G.S. lines or the total flux, which issuing from any one pole flows through the armature core, to leave it by another pole of opposite sign. Since each inductor cuts these lines, first, as they enter into the armature core from one pole, and then as they emerge from it to enter another pole, the total number of lines cut in one revolution by any one inductor is $2pZ_a$. The time in seconds taken to perform one complete revolution is $\frac{60}{N}$, where N is the number of revolutions per minute. The average E.M.F. induced in each inductor in one revolution, being proportional to the total number of lines which it cuts, divided by the time taken to cut them, is therefore $2p \cdot \frac{N}{60} \cdot Z_a \times 10^{-8}$ volts. Let $\tau$ be the total number of inductors on the surface of the armature, whether ring- or drum-wound, and let $q$ be the number of parallel circuits into which the armature winding of a continuous-current dynamo is divided, whence the number of inductors in series is $\frac{\tau}{q}$. The average E.M.F. induced in the armature is then $E_a = 2 \cdot \frac{pN}{60} \cdot \frac{\tau}{q} \cdot Z_a \times 10^{-8}$ volts, and in the continuous-current machine, with a sufficient number of inductors and commutator sectors, this is the same as the instantaneous E.M.F.; for the sum total of the several E.M.F.'s set up in the different inductors of one circuit, spread uniformly over the armature core, will at any moment be equal to the average E.M.F. set up in one inductor multiplied by the number of inductors in series, *i.e.*, it is independent of the distribution of the flux in the air-gap. It should be observed that $Z_a$, or the number of lines flowing *through* the armature, is taken, since in the ring machine this will differ from the number that cross the air-gap or $Z_g$ by the small percentage which leak across the interior of the ring, and so are cut in the opposite sense by the internal connecting wires.

[1] Except in the special case of multiple-circuit windings, which will be referred to later.

The case of the discoidal armature may best be treated by reducing it to the analogous simple ring; each pair of opposing poles, since they are of the same sign, forms in effect a single divided pole, whence a total number of lines $Z_a$ pass into the armature core; $\tau$ must then be reckoned as equal to the number of loops in the ring, or the number of inductors on one only of its two faces. The equation of E.M.F. thus becomes exactly the same as that of the simple ring machine. The disc winding is analogous to the drum, so that in all cases *the E.M.F. of the continuous-current closed-coil armature* is

$$E_a = \frac{2}{q} \cdot \frac{pN}{60} \cdot \tau \cdot Z_a \times 10^{-8} \text{ volts}, \qquad \text{(I.}a\text{)}$$

where $q$ must be an even number, and can never be less than 2.

In the continuous-current dynamo the instantaneous and average values of the E.M.F. from the armature as a whole are the same; but when we pass to the alternator, its "effective" E.M.F. is equal to the square root of the mean square of the instantaneous values of the E.M.F., since this is the value of the equivalent unidirected and unvarying E.M.F., which, when applied to a given resistance or to a glow lamp, would give the same amount of heat or of light as the alternating E.M.F. produces (see ELECTRICITY, iii. *Electric Current*). The shape of the curve of instantaneous E.M.F. therefore becomes a matter of the greatest importance, for upon it will depend the effective voltage of the alternator, even though its average E.M.F. may be the same with some different shape of E.M.F. curve. Assuming, as we may, that the density of the lines is the same along the length of an inductor for any given position of it during rotation, its instantaneous E.M.F., $= B_g L V \times 10^{-8}$ volts, will vary as $B_g$ varies, according to the position of the inductor under or between the poles. Hence the addition of more inductors in series may not give a proportionate addition of E.M.F., and in fact will not do so, unless they are so close beside each other that their difference of spacial position or of phase can be neglected; the nearest practical approach to this will be in the case of a toothed or tunnel armature, when the inductors of a coil are wound in the same slot or hole. Differential action, which has been already discussed, is indeed only an aggravated case of the same effect as must take place when a coil is gradually coming into or out of action, and is not entirely under a pole. Further, it is evident that the curve of E.M.F. of the coil may be given any shape that we please, by so shaping the pole-piece as to give the required variation in density of the lines in the air-gap. Thus the length of gap between pole-face and armature core might be so varied as to give a curve of E.M.F. varying after a sine law (cp. Fig. 3—for the case of a single inductor), and the ratio of the effective E.M.F. to the average E.M.F. would then have the particular value of $\frac{\pi}{2\sqrt{2}} = 1 \cdot 11$. Two points have, then, to be considered in an alternator, namely, what is the ratio of the square root of the mean square to the average value of its E.M.F., and what is the ratio which either the instantaneous or the average E.M.F. of a coil bears to the instantaneous or average E.M.F. of a single inductor. Both depend on the ratio of the width of coil and pole, and on the law which governs the variation in density of the field. If $e_c$ = the effective E.M.F. of one coil, and the total number of coils in one phase, *i.e.*, $2p$, be divided into $q$ parallels, the effective E.M.F. of the phase is $E_{ae} = \frac{2p}{q} \cdot e_c$. Let $k'$ = the ratio of the square root of the mean square to the average value of the E.M.F. of the coil, or $= \dfrac{\sqrt{\dfrac{\int_0^T e^2 dt}{T}}}{\dfrac{\int_0^T e\,dt}{T}}$, then the effective value of the E.M.F. of the phase is $\frac{2p}{q} \cdot k' \cdot e_{av}$, where T is the time of a period and $e_{av}$ = the net average value of the E.M.F. of a coil. Let $k''$ = the ratio which the net average E.M.F. of the coil bears to the gross average E.M.F. on the supposition that there is no differential action, and let $e$ = the average E.M.F. of a single inductor; then if $t$ be the number of inductors in a coil, the reduction of the E.M.F. of a coil as a whole may be taken into account by multiplying the product $te$ by a breadth coefficient $k''$, which must be less than unity if the coil have any width. The effective E.M.F. per phase is therefore $\frac{2p}{q} \cdot k' \cdot k'' \cdot te$. If $m$ = the number of separate phases into which the armature winding is divided, $t = \frac{\tau}{m \cdot 2p}$; further, the average E.M.F. of the single inductor $e$ is $2 \cdot \frac{pN}{60} \cdot Z_a \times 10^{-8}$ volts; whence the *effective E.M.F. of one phase of the alternator* is
$E_{ae} = \frac{2p}{q} \cdot k' \cdot k'' \cdot \frac{\tau}{m \cdot 2p} \cdot \frac{2p \cdot N}{60} \cdot Z_a \times 10^{-8} = \frac{2 \cdot k' \cdot k''}{m \cdot q} \cdot \frac{pN}{60} \cdot \tau Z_a \times 10^{-8}$ volts. The two factors $k'$ and $k''$ may be united into one constant

K, and the equation then takes its final form of

$$E_{ae} = \frac{2 \cdot K}{mq} \cdot \frac{pN}{60} \cdot \tau \cdot Z_a \times 10^{-8} \text{ volts} \quad . \quad . \quad . \quad . \quad (\text{I}.b)$$

In contrast to the continuous-current dynamo, $q$ may be unity. The analogy of this equation to that of the continuous-current machine is at once apparent; the process by which it is arrived at really consists in stating the E.M.F. of the alternator as that of a similarly wound continuous-current dynamo multiplied by a certain constant, and only because this is the most convenient method of expressing it are we interested in its average E.M.F. The second term $\frac{p \cdot N}{60}$ in both equations gives the periodicity of the alternating E.M.F. in the inductors; and even though the current be commuted, as in the continuous-current machine, it is of importance as determining the loss by hysteresis in the core, and by eddy currents in the armature as a whole.

The fundamental equation of the electromotive force of the dynamo in its fully developed forms (I.$a$) and (I.$b$) may be compared with its previous simple statement (I.). The three variable terms still find their equivalents, but are differently expressed, the density $B_g$ being replaced by the total flux of one field $Z_a$, the length L of the single inductor by the total number of inductors $\tau$, and the velocity of movement V by the number of revolutions per second. Even when the speed is fixed, an endless number of changes may be rung by altering the relative values of the remaining two factors; and in successful practice these may be varied between fairly wide limits without detriment to the working or economy of the machine. While it may be said that the equation of the E.M.F. was implicitly known from Faraday's time onwards, the difficulty under which designers laboured in early days was the problem of choosing the correct relation of $Z_a$ and $\tau$ for the required output; this, again, was due chiefly to the difficulty of predetermining the total flux before the machine was constructed.[1] The general error lay in employing too weak a field and too many inductors, and credit must here be given to the American inventors, Weston and Edison, for their early appreciation of the superiority in practical working of the drum armature, with comparatively few inductors rotating in a strong field.

The *equation of mechanical force* now requires to be given, in its turn, a more fully developed form correlative to that of the electromotive force. Let the inductors of a continuous-current dynamo be carrying a current of $c$ amperes; then each, so long as it is moving under a pole-face, is subjected to a mechanical drag of $B_g L c \times 10^{-1}$ dynes, or if the length and force be expressed in English units of inches and pounds, of 57 $B_g L'' c \times 10^{-8}$ pounds. This force is gradually removed and re-established $2p$ times in each revolution as the inductor passes the interpolar gaps, but its direction is always tangential to the path of rotation, and opposed to it, so that the torque resisting the movement of a single inductor is $B_g L c \cdot r \times 10^{-1}$ dyne-centimetres, where $r$ is the radius in cm. of the mean path of the inductor. The total torque acting on the armature is due to the combined effect of the several inductors with which it is wound; and since the number of inductors within one polar face is $\tau \cdot \frac{\phi}{2\pi}$, where $\phi$ is the angle subtended by the polar arc in radians, the total torque of the armature due to the $2p$ fields is $T = p \cdot \tau \cdot \frac{\phi}{\pi} \cdot B_g \cdot L \cdot c \cdot r \times 10^{-1}$ dyne-centimetres.

Since $B_g = \frac{Z_a}{Lr\phi}$,

$$T = \frac{p \cdot \tau \cdot c \cdot Z_a}{\pi} \times 10^{-1} \text{ dyne-centimetres, or}$$

$$= \frac{p \cdot \tau \cdot c \cdot Z_a}{4.26} \times 10^{-8} \text{ pound-feet} \quad . \quad . \quad . \quad . \quad (\text{II}.a).$$

In the above statement the lines are treated as if confined strictly to the area of the pole-face—an assumption which is not strictly true, since the fringe surrounding the pole-edges has been neglected. The correction for this slightly decreases the value of $B_g$ for a given value of $Z_a$, but correspondingly increases the number of inductors which are subjected to the torque, so that the final form of the equation is strictly true for the continuous-current armature as a whole. This may be proved if the torque be multiplied by the angular velocity in radians per sec., and the rate of absorption of mechanical energy as thus obtained in ergs per sec. or foot-pounds per sec. be equated to the rate of development of electrical energy. The latter is equal to E C watts, or since $C = qc$, the electrical horse-power is

$$\frac{2}{q} \cdot \frac{pN}{60} \cdot \frac{\tau \cdot Z_a \cdot 10^{-8}}{746} \cdot qc = \frac{2pN}{60} \cdot c \cdot \tau \cdot Z_a \times 1.33 \times 10^{-11}.$$

On the other hand, the angular velocity in radians per sec. is equal to the number of revolutions per sec. multiplied by $2\pi$, so that the mechanical horse-power absorbed is equal to

$$\frac{p \cdot \tau \cdot c \cdot Z_a}{4.26} \times 10^{-8} \times \frac{2\pi N}{60} \times \frac{1}{550} = \frac{2pN}{60} \cdot c \cdot \tau \cdot Z_a \times 1.33 \times 10^{-11}.$$

Since the expression for the drag on any single inductor involves the term $B_g$, it is evident that it is dependent on the distribution of the flux in the air-gap, *i.e.*, on the shape of the curve of $B_g$, and if the average value of $B_g$ is alone considered, the equation (II.$a$), although giving the average pull on the inductor, does not express its instantaneous values. As will be explained subsequently, the value of the actual $B_g$ in the continuous-current dynamo when at work is not uniform even under the pole-face. Hence the instantaneous pull on any inductor varies on either side of the average value, and in practice its maximum value at full load may be as much as 20 per cent. greater than the average value.

Lastly, in the alternator the current $c$ varies as well as the density $B_g$, so that the problem becomes much more complicated and no simple equation can express it. If the current in the armature were in phase with the induced E.M.F., and so with the flux-density which causes it, the maxima values of $B_g$ and $c$ would occur simultaneously. The maximum drag thereby produced will be far greater than the average value, and may considerably exceed the force acting on the equivalent continuous-current dynamo. But, more than this, if there be inductance in the circuit, the current in the armature will lag in phase behind the induced E.M.F. and behind the $B_g$ curve. The pull on the inductors now becomes zero not only when $B_g$ is zero, but also when $c$ is zero, and, further, its direction relatively to the rotation changes each time that either the one or the other passes through zero. Thus the alternator is subjected to a racking action which is much more trying than the simple torque of the continuous-current machine. The armature is alternately dragged back when the directions of field and current coincide, and driven forward as a motor when they are opposed, the backward drags being more powerful and lasting longer than the forward pushes, so that on the whole the machine absorbs mechanical energy and acts as a generator.

If the inductors, instead of being wound on the surface of a smooth armature core, are sunk into slots or passed through holes close to the edges of the core-discs, the force which would otherwise be expended on them is largely transferred to the iron teeth which project between the slots or tunnels. The lines of the field, after passing through the air-gap proper, divide between the teeth and the slots in proportion to their relative permeances. Hence at any moment the inductors are situated in a weak field, and for a given armature current the force on them is only proportional to this weak field.[2] This surprising result is connected with the fact that when the armature is giving current the distribution of the lines over the face of each tooth is distorted, so that they become denser on the "trailing" side than on the "leading"[3] side (Fig. 17); the lines tend to straighten and shorten themselves, and the result of the unsymmetrical distribution acting on all the teeth is to produce a magnetic drag on the armature core proportional to the current taken out of the inductors, so that the total resisting force remains the same as if the armature had a smooth core. The amount by which the stress on the inductors is reduced entirely depends upon the degree to which the teeth are saturated, but since the relative permeabilities of iron even at a flux density of 20,000 lines per square centimetre is to that of air as 33 : 1, the embedded inductors are very largely relieved of the driving stress.

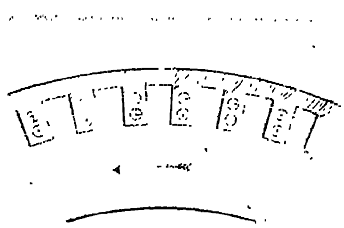

Fig. 17.

### Continuous-Current Dynamos.

On passing to the separate consideration of continuous-current dynamos, the winding of the armature may first be taken in greater detail, and certain results drawn from

[1] Cp. Kapp, *Journ. Soc. Tel. Eng.* vol. xv. p. 5901, 886.

[2] *Electrician*, vol. xxxiv. p. 757 (Sayers), and vol. xli. p. 108 (Du Bois); Swinburne, *Industries and Iron*, February 2, 1894; Mordey, *Journ. Inst. Elec. Eng.* vol. xxvi. p. 564; Houston and Kennelly, *Elec. Eng.* vol. xviii. p. 208.

[3] By the "leading" side is to be understood that side which first enters under a pole after passing through the gap between the poles, and the edge of the pole under which it enters is here termed the "leading" edge, as opposed to the "trailing" edge or corner from under which a tooth or coil emerges into the interpolar gap; cp. Fig. 30, where the leading and trailing edges are marked $ll$ and $tt$.

the ring and drum armatures of Fig. 16, which are equally true for the discoidal and disc forms.

**Ring winding.** The simple ring winding consisting of a continuous helix is in itself unaffected by the number of poles; by the mere placing of $2p_{\prime}$ sets of brushes on the surface of the commutator at equal distances apart, the winding is at once divided into as many equal and symmetrical paths through the armature, or $q=2p_{\prime}$. Hence if $2p_{\prime}$ is made equal to $2p$ or the number of poles, a *multipolar parallel-wound ring* is obtained, having as many parallel circuits and as many points of collection of the current as there are poles. The E.M.F. of the armature is then $\frac{2p}{2p_{\prime}} \cdot \frac{N}{60} \cdot \tau \cdot Z_a \times 10^{-8} = \frac{N}{60} \cdot \tau \cdot Z_a \times 10^{-8}$ volts, whether it be bipolar or multipolar, and the current in any one inductor is $\frac{C}{2p}$. All the sets of brushes which are of the same sign must be connected together in order to collect the total current C. The potential rises gradually in the armature wires as we pass from a negative to a positive brush, or falls as we proceed onwards from a positive to a negative brush. The difference of potential between adjacent wires is only that due to the added voltage of one inductor if the winding be in one layer, or to one section if there be several layers; and as this is but a few volts even in machines giving as much as 3000 volts at the terminals, the insulation of the wires from one another presents no difficulty. On this score the ring winding contrasts favourably with the drum, and it is therefore more especially suited to very high potential machines. If the increased number of brush-sets in the multipolar parallel-wound armature is regarded as a disadvantage, they may again be reduced to two by cross-connexion of sectors situated $\frac{360°}{p}$ apart; but the commutator must then be lengthened $p$ times in order to provide sufficient brush-contact surface to collect the total current C, and, further, the number of sections must be an even number.

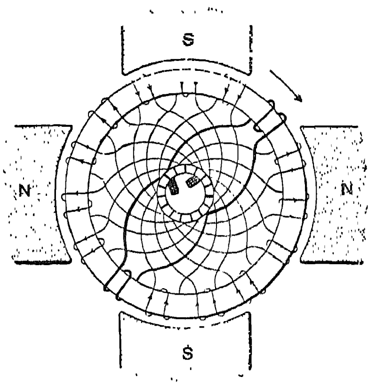

Fig 18.

It is, however, often required to add together the inductive effect of sections of the winding situated under two or more poles, especially in high voltage machines. This may be done by connecting together in series a set of coils symmetrically situated in fields of like polarity, as diagrammatically shown in Fig. 18; the current in the armature is then only divided between two parallel paths, and there are only two sets of brushes, or $p_{\prime}=1$ and $q=2p_{\prime}=2$. Hence the E.M.F. of the *series-wound multipolar armature* is $E_a = p \cdot \frac{N}{60} \cdot \tau \cdot Z_a \times 10^{-8}$ volts.

**Drum winding.** The development of the modern *drum winding* from the shuttle-wound Siemens armature is chiefly due to von Hefner Alteneck of Berlin (1871). From Fig. 16B it will be seen that, in order to avoid differential action, the width of each loop must exceed the width of a pole-face and may be equal to the pitch of the poles, *i.e.*, the loop may be wound diametrically across the bipolar armature core. If, however, the number of commutator sectors be even and the winding be disposed in one layer, a symmetrical winding cannot be obtained unless the width of the loop falls short of the above maximum width by at least the width of one inductor, *i.e.*, the "pitch" of the loop at the "back" end of the armature farthest from the commutator, or the number of inductors passed through in joining one inductor to another, must not exceed $\frac{\tau}{2}-1$. Since $\frac{\tau}{2}$ is with an even number of sectors itself also an even number, the pitch at the back end of the armature must then be an uneven number. Even if the armature winding be disposed in two layers, or the commutator sectors be an uneven number, it is not advisable for the loops to be wound diametrically across the armature core; hence it may be said in general that the pitch of the winding at the back end of the armature must be an uneven number less than $\tau/2$, so that the loop spans a chord less than the diameter, and is in effect wound on one side of the core (cp. Fig. 16B). In completing the loop and joining it to the next loop, two possible cases present themselves. By the first, or *lap winding* (Fig. 16), the end of the loop is taken to a commutator sector, and thence starts off again to a third inductor on the same side of the core as the first loop, and lying within its two sides, *i.e.*, the next loop starts with the inductor next but one to the first inductor. The pitch of the front end is therefore less than the pitch of the back end, and differs from it by two. Thus the winding works continually forwards and backwards, until it passes right round the armature and finally closes on itself. The development on a flat surface shows that the completed winding takes the form of a number of partially overlapping loops, whence its name originates. One of these loops is marked in heavy lines in Fig. 19 i., where the firm-line portion gives the development of Fig. 16B, if cut through at the point marked X. The multipolar parallel-wound drum is precisely similar, as shown by the dotted additions in Fig. 19 i., which convert it from a two-pole to a four-pole armature; the only difference is that the pitch at the back end must in all cases be an odd number less than, but not far different from, $\tau/2p$. The maximum difference of potential in the drum armature exists between neighbouring wires as they successively pass the neutral points corresponding to the position of the brushes, and is here equal to the full E.M.F. of the machine. These wires lie side by side in the smooth-core armature with one layer, or one on the top of the other if there are two layers, as is usually the case in slotted

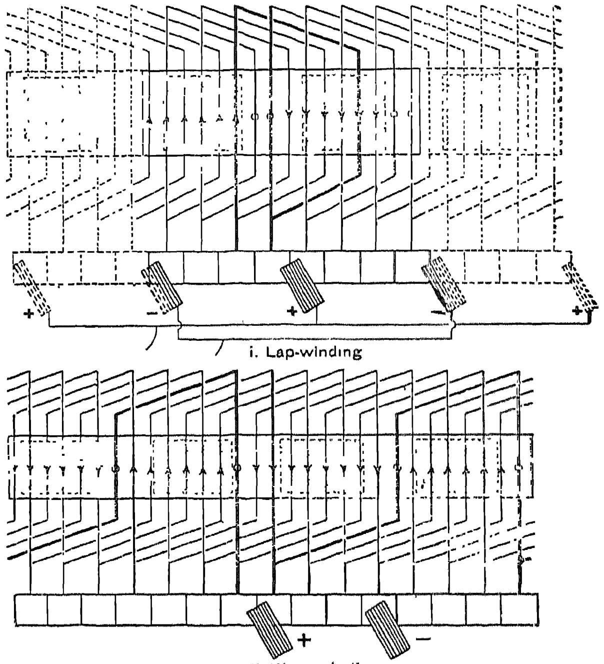

Fig. 19.

armatures; so that good insulation must be provided between the adjacent sides of the wires in the former case, and between the two layers in the latter case.

**Wave winding.** By the second, or *wave*, method of drum winding, the end of the first loop in the bipolar armature is taken to a commutator sector on the opposite side of the diametric line to the first loop, and thence the second loop starts with an inductor lying *outside* the first loop and next but one to the original inductor. The method may be extended to multipolar machines, and then gives the series-wound multipolar armature; when the completed winding is developed on a flat surface (Fig. 19 ii.), it is seen to work continuously forwards in a zigzag wave round the armature, one inductor under each pole being successively joined up until the winding closes on itself. The average of the front and back pitches must be $\frac{\tau \pm 2}{2p}$, so that, *e.g.*, in a four-pole machine, the possible number of inductors goes up by steps of four.

The equations of the E.M.F. of parallel-wound and series-wound drum armatures are the same as those for the parallel-wound and series-wound rings, the latter in each case being $p$ times the former. Thus the chief advantage of the series-wound armature, whether ring or drum, is that for a given voltage the number of inductors and the space lost in insulation of the wires is only $1/p$ of the number of inductors and the space lost in the parallel-wound armature. A further advantage is that the two circuits from brush to brush consist of inductors influenced by all the poles in the drum, or by all the poles of like sign in the ring; hence

if for any reason, such as eccentricity of the armature in the bore of the pole-pieces, the inductive effect of one field is not equal to that of any other, the equality of voltage produced by the two halves of the winding is not affected thereby. In the parallel-wound armature inequality of the voltage of the various parallels may be avoided by a combination of the series and parallel methods. For large currents, multiple circuits are possible both with series and parallel winding, and $q=2p, \times x$, where $x=$ the number of separate armatures which are virtually wound on the same core.

***Armature core.*** When the core of the armature is constructed of iron or other metal, the passage of it through the lines of the field sets up in its mass E.M.F.'s which are in opposite directions under poles of opposite sign, and are greatest at the surface where the rate of line-cutting is greatest. Hence if the core were a solid mass, a current-sheet would flow along its surface under each pole, and complete its circuit by passing through the inner parts of the core or by returning in a sheet under a pole of opposite sign. The result would be a considerable reduction in the efficiency of the machine, since the power absorbed by these so-called *eddy-currents* would be entirely dissipated in heating the core. The production of the E.M.F. cannot be prevented, but the paths of the eddy-currents can be broken up, so that they meet with a comparatively high resistance and are reduced in amount. In the first place, the metal core must be divided into laminations whose planes are at right angles to the length of the inductors proper, since these are arranged to secure the maximum E.M.F. The laminae must be slightly insulated from one another; and if the insulation be maintained right up to their edges, the E.M.F.'s which still act across their thickness will not be added up along the length of the core, but will only produce very small currents, which circulate through the interior of the separate laminations. This remedy is practically realized in ring and drum armatures by building up their cores of thin iron plates or discs, strung on the shaft or on a supporting hub, so that their edges are presented to the lines of the field. Each disc is either coated with an insulating varnish or has one of its sides covered with a sheet of very thin paper; or in some cases no special insulating material is employed, and reliance is placed on the thin film of oxide which forms on the disc in the process of manufacture, and which is a poor electrical conductor. The thickness of the discs is usually about one-fortieth of an inch, and if this be not exceeded, the eddy-currents set up in the mass of the core are reduced to an almost negligible amount. The discs are in the ring machine notched with three or more key-ways, and are then passed over a gun-metal hub with three or more arms running parallel to the shaft, which fit into the corresponding slots on the inner periphery of the discs (cp. Fig. 6 and the sections of Fig. 13). In the case of small bipolar drums the discs are often keyed directly to the shaft, but in larger multipolar machines the required radial depth of iron is small, and the discs are then mounted on a hub similar to that of the ring armature, save that it may now be made of cast-iron. If the armature is more than 4 feet in diameter, the discs become too large to be conveniently made in one piece, and are therefore divided into segments, which are built up so that they alternately break joint. In all cases the stout end-plates between which the discs are clamped together must be kept well out of the influence of the field, since otherwise the lines which curve round into the ends of the core from the edges of the poles may cause eddy-currents in their mass. Hence the axial length of the core is often made slightly greater than the corresponding dimension of the poles. In discoidal-ring armatures the laminations must be concentric with the axis of rotation, and a thin ribbon of iron is wound on the supporting wheel, which may be of cast-iron (cp. Figs. 10 and 13 ii.).

***Armature winding.*** When the armature core has been built up and all rough edges smoothed off, it is covered with some material of good insulation, resistance, and durability, such as oiled linen, varnished paper, or micanite sheeting, so that all edges and surfaces on which the winding rests are thoroughly protected. In the ring wire-wound armature a length of wire sufficient for one section of the armature is cut off, treated with shellac, and dried; one end is passed through the interior of the ring, and the required number of loops are wound tightly round the core. The next section is then similarly wound, until finally the whole core is covered, and the beginnings and ends of contiguous sections are united at the commutator to form a continuous helix. If the size of the solid wire becomes too large to be conveniently bent, two or more wires may be wound in parallel, with, however, some necessary loss of space owing to the subdivision. The small drum armature may be similarly *hand-wound*, the loops of wire overlapping at the ends of the armature core; but the method is accompanied by the disadvantage that if one section has to be repaired, the whole armature may have to be taken to pieces and rewound. Hence various methods have been devised for winding drums with coils formed on shapers previously to fixing them in place. The *former-wound* coils have the advantage that they are perfectly symmetrical and interchangeable, can be thoroughly insulated before they are placed on the core, and, further, are economical in cost of labour. If, however, the current in each inductor is large, the drum armature must be *bar-wound*. The inductors are then large and heavy bars of rectangular section, which are laid on the core and joined up in regular sequence by soldering to the end-connectors. These latter are strips of copper from one to two inches wide, which are bent in a double evolute curve so that they span the correct pitch and unite the short end of one bar to the long end of another bar situated at the proper distance apart round the circumference of the core. For multipolar armatures with two or more layers of inductors, "surface" or "*barrel*" winding is now extensively used, in which no separate end-connectors are employed; at each end the inductors project beyond the core and are bent through an angle corresponding nearly to half the pitch of the poles, the upper layer being bent in the opposite direction to the lower; the ends of the two layers are then soldered together to form loops lying entirely on the surface of the cylindrical armature.

Since any inductor must have a certain width in the direction of rotation, one edge enters or leaves the field sooner than the other edge. Hence when a solid bar is moving through the fringe of lines between the pole-tips, where the density varies considerably, the E.M.F. set up along the one edge is different from that set up along the other, and an eddy-current will flow round the bar, passing down one side and up the other, due to the difference between the E.M.F.'s of the two edges. Thus in a rotating armature an eddy-current will be set up in each and every solid bar as it passes between the pole-tips. To prevent the reduction in efficiency that results therefrom, and the consequent heating of the bar, it is necessary to make use of a stranded bar in which the separate strands, lightly insulated from each other, are twisted so that they pass from one side to the other, at least once midway along the length of the bar. The E.M.F. induced in each strand is then practically the same, since it is the average of the E.M.F.'s of the two sides, and the eddy-current loss is very largely avoided.

***Driving the inductors.*** In every dynamo with rotating armature the driving force has to be transmitted from the shaft or coupling to the hub, thence to the discs, and finally to the inductors. The discs must therefore be securely keyed to the hub, and in the smooth-surface armature any slip between the core and the inductors is opposed by the friction between the two. The bands of binding wire, which are placed at intervals along the length of the armature in order to resist the stress of centrifugal force, further increase the friction. In the wire-wound ring the loops themselves grip the core tightly, and are also held in place by passing through the interior of the ring between the arms of the hub. But in the smooth-core drum the firm attachment of the inductors to the core presents greater difficulties, and in order to ensure the positive driving of the bars through the magnetic field against the mechanical drag, it is usual to groove a number of longitudinal slots in the periphery of the core at equal distances apart of some four inches, and to drive tightly into these hard-wood driving strips, which project from the core to a height equal to that of the inductors. Thus the inductors are split up into groups, and the combined drag due to a group is taken up by a corresponding strip. A still more perfect method of driving is found in the toothed or slotted core. This was the original type of armature invented by Pacinotti, but after some considerable use it was largely discarded in favour of the smooth core; of recent years, however, it has again been reintroduced, with a fuller understanding of the special precautions

required in its design, and it has met with great success in the construction of traction dynamos, in which the stresses set up by the varying load are very great. Not only are the bars securely driven by the teeth, but, as previously mentioned, they are largely relieved of the driving stress. A further advantage is due to the fact that the lines snap across the inductors from tooth to tooth with a velocity far in excess of the speed of rotation. The product of the weaker density in the slots and the increased velocity of the relative movement gives the same E.M.F. as in the equivalent smooth-core armature, but owing to the comparatively uniform density of the lines within any one slot, and the extremely rapid rate at which they cut the inductors, solid bars of much greater width may be used in the toothed armature than on a smooth core without trouble from eddy-currents.[1] One disadvantage of the slotted core remains to be mentioned. If the top of the slot be open, and its width of opening be considerably greater than the length of the single air-gap from the iron of the pole-piece to the surface of the core, the lines become unequally distributed not only at the surface of the teeth, but also at the bored face of the pole-pieces; and this massing of the lines into bands causes the density at the pole-face to be rhythmically varied as the teeth pass under it. No such variation can take place in a solid mass of metal without the production of eddy-currents within it; hence if the proportion[2] of the width of slot-opening to the length of air-gap is equal to or exceeds 2 : 1, it becomes advisable to laminate the pole-pieces to avoid eddy-currents in them. This precaution is less necessary with half-closed slots, and is entirely unnecessary with tunnel armatures, in which the inductors are threaded through holes pierced close to the surface of the core; but we are then met with the difficulty that such closed, or nearly closed, slots greatly increase the inductance of the loops, and are therefore disadvantageous to the commutation and sparkless collection of the current.

On passing to the second fundamental part of the dynamo, namely, the field-magnet, its functions may be briefly recalled as follows:—It has to supply the magnetic flux; to provide for it an iron path as nearly closed as possible upon the armature, save for the air-gaps which must exist between the pole-system and the armature core, the one stationary and the other rotating; and, lastly, it has to give the lines such direction and intensity within the air-gaps that they may be cut by the armature inductors to the best advantage. Roughly corresponding to the three functions above summarized are the three portions which are more or less differentiated in the complete structure. These are: (1) the magnet "cores" or "*limbs*," carrying the exciting coils whereby the inert iron is converted into an electro-magnet; (2) the *yoke*, which joins the limbs together and conducts the flux between them; and (3) the *pole-pieces*, which face the armature and transmit the lines from the limbs through the air-gap to the armature core, or *vice versâ*.

***Forms of field-magnet.***

Of the countless shapes which the field-magnet may take, it may be said, without much exaggeration, that almost all have been tried; yet those which have proved economical and successful, and hence have met with general adoption, may be classed under a comparatively small number of types. For bipolar machines the *single horse-shoe* (Fig. 20), which is the lineal successor of the permanent magnet employed in the first magneto-electric machines, has been very largely used, and for all outputs up to 150 kilowatts remains one of the simplest, most economical, and most compact types. It takes two principal forms, according as the pole-pieces and armature are above or beneath the magnet limbs and yoke. The "over-type" form is best suited to small belt-driven dynamos, while the "under-type" is admirably adapted to be directly driven by the steam-engine, the armature shaft being immediately coupled to the crank-shaft of the engine, and the axis of rotation being thus kept low. In the latter case the magnet must be mounted on non-magnetic supports of gun-metal or zinc, so as to hold it at some distance away from the iron bed-plate which carries both engine and dynamo; otherwise a large proportion of the flux which passes through the magnet limbs would leak through the bed-plate across from pole to pole without passing through the armature core, and so would not be cut by the armature inductors. The field-system is thus—to use a somewhat inaccurate expression—"magnetically insulated" from the bed-plate, the intervening distance being some eight to ten times the length of the single air-gap.

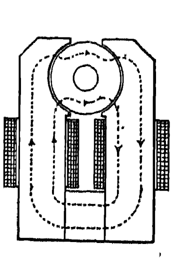

Fig. 20.

Next may be placed the "*Manchester*" field (Fig. 21)—the type of a divided magnetic circuit in which the flux forming one field or pole is divided between two magnets. An exciting coil is placed on each half of the double horse-shoe magnet, the pair being so wound that consequent poles are formed above and below the armature. Each magnet thus carries one-half of the total flux, the lines of the two halves uniting to form a common field where they issue forth into or leave the air-gaps. Or the coils may be divided and placed on the limbs of each horse-shoe, as in Fig. 22, instead of on the yoke, as in Fig. 21. The pole-pieces in both cases may be lighter than in the single horse-shoe type, and the field is much more symmetrical, whence it is well suited to ring armatures of large diameter. Yet these advantages are greatly discounted by the excessive magnetic leakage, and by the increased weight of copper in the exciting coils. Even if the greater percentage which the leakage lines bear to the useful flux is neglected, and the cross sectional area of each magnet core is but half that of the equivalent single horse-shoe, the weight of wire in the double magnet for the same rise of temperature in the coils must be some 40 per cent. more than in the single horse-shoe, and the rate at which energy is expended in heating the coils will exceed that of the single horse-shoe in the same proportion.

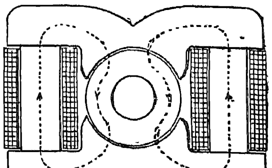

Fig. 21.

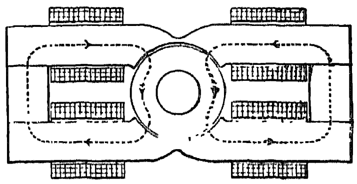

Fig. 22.

A somewhat similar form of two-pole field is required by the discoidal machine, but the poles now face the sides of the flat-ring armature (cp. Fig. 13 ii.); opposite poles of similar sign may be joined together by an overarching pole-piece, but owing to the difficulty of avoiding eddy-currents in the core it is more usual for the magnetic circuits to be entirely divided.

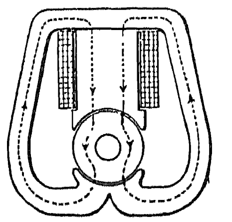

Fig. 23A.

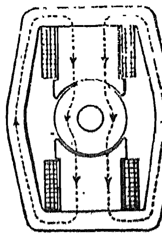

Fig. 23B.

Fourthly comes the two-pole *ironclad* type, so called from the exciting coil being more or less encased by the iron yoke; this latter is divided into two halves, which pass on either side of the armature. Unless the yoke be kept well away from the polar edges and armature, the leakage across the air into the yoke becomes considerable, especially if only one exciting coil is used, as in Fig. 23A; it is better, therefore, to divide the excitation between two coils, as in Fig. 23B, when the field also becomes symmetrical.

From this form is easily derived the *multipolar* type[3] of Fig. 24, which is by far the most usual for any number of poles from four upwards; its leakage coefficient is but small, and it is economical in weight both of iron and copper. The multipolar discoidal magnet takes the shape shown in the four-pole machine of Fig. 25, with which may be compared Fig. 13 ii. Another four-pole type (Fig. 26) may also be derived from Fig. 23B, if we suppose the

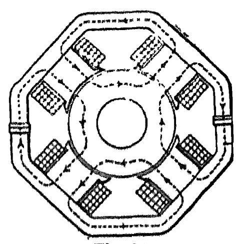

Fig. 24.

yoke on either side of the armature to be pushed inwards until it nearly meets the armature on a horizontal diameter, and the direction of winding of one coil to be changed. Two salient poles and two consequent poles are thus obtained, and the machine is like that of Fig. 24, but with only two poles wound. The leakage across from pole to pole is great in a four-pole magnet of this type,

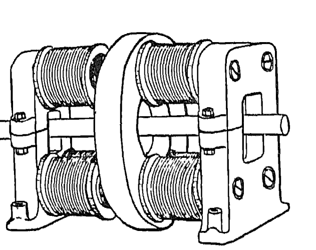

Fig. 25.

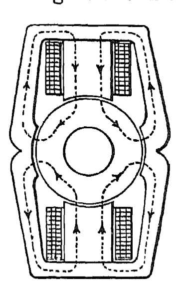

Fig. 26.

but in alternators where a large number of poles are required it may be convenient to wind only half their number, owing to their close proximity to one another. The multipolar equivalent of Fig. 21 is shown in Fig. 27, and again the weight of copper on the divided magnetic circuits must be greater than in the preceding multipolar magnets. Fig. 28, which is best suited to four

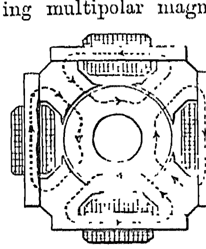

Fig. 27.

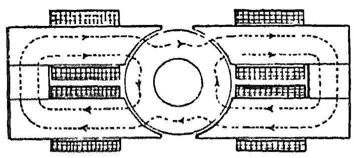

Fig. 28.

poles, may be obtained from Fig. 22 by dividing the pole-pieces and reversing the direction of winding on one side. The two single horse-shoe magnets thus formed have the peculiarity that half of the flux passing from one pole returns at once through the armature core to the opposite pole of the same magnet, while half passes onwards to a pole of the second magnet. Lastly, the multipolar magnet of Fig. 29, in which there is only one magnetizing coil enclosed between overarching claws forming the poles, those of one sign projecting into the gaps between the others of opposite sign, is economical in the weight of copper in its single coil, but the leakage between the sides of adjacent poles is considerable.

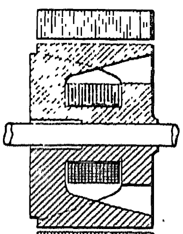

Fig. 29.

**Materials of magnets.**

As regards the materials of which magnets are made, generally speaking there is little difference in the permeability of *wrought-iron* or *mild-steel forgings* and good *cast-steel*; typical (B,H) curves connecting the magnetizing force required with different flux-densities for these materials are given under ELECTROMAGNET. On the other hand, there is a marked inferiority in the case of *cast-iron*, which for a flux-density of B = 8000 requires practically the same number of ampere-turns per centimetre length as steel requires for B = 16,000. Whatever the material, if the flux-density be pressed to a high value the ampere-turns are very largely increased owing to its approaching saturation, and this implies either a large amount of copper in the field coils or an undue expenditure of electrical energy in their excitation. Hence there is a limit imposed by practical considerations to the density at which the magnet should be worked, and this limit may be placed at about B = 16,000 for wrought-iron or steel, and at half this value for cast-iron. For a given flux, therefore, the cast-iron magnet must have twice the sectional area and be twice as heavy, although this disadvantage is partly compensated by its greater cheapness. If, however, cast-iron be used for the portion of the magnetic circuit which is covered with the exciting coils, the further disadvantage must be added that the weight of copper on the field-magnet is much increased, so that it is usual to employ forgings or cast-steel for the magnet cores on which the coils are wound. If weight is not a disadvantage, a cast-iron yoke may be combined with the wrought-iron or cast-steel magnet cores. An absence of joints in the magnetic circuit is only desirable from the point of view of economy of expense in machining the component parts during manufacture; when the surfaces which abut against each other are drawn firmly together by screws, the want of homogeneity at the joint, which virtually amounts to the presence of a very thin film of air, produces little or no effect on the total reluctance by comparison with the very much longer air-gaps surrounding the armature. In order to reduce the eddy-currents in the pole-pieces, due to the use of toothed armatures with relatively wide slots, the pole-pieces must be laminated in the same direction as the armature core is laminated; the poles are then built up of thin sheets of charcoal iron or mild steel, and these are sometimes fixed by casting them into the outer yoke-ring.

However it be built up, the mechanical strength of the magnet system must be carefully considered. Any two surfaces between which there exists a field of density $B_g$ experience a force tending to draw them together proportional to the square of the density, and having a value of $\frac{B_g^2}{1{\cdot}735 \times 10^6}$ lb per square inch of surface, over which the density may be regarded as having the uniform value $B_g$. Hence, quite apart from the torque with which the stationary part of the dynamo tends to turn with the rotating part as soon as current is taken out of the armature, there exists a force tending to make the pole-pieces close on the armature as soon as the field is excited. Since both armature and magnet must be capable of resisting this force, they require to be rigidly held; although the one or the other must be capable of rotation, there should otherwise be no possibility of one part of the magnetic circuit shifting relatively to any other part. An important conclusion may be drawn from this circumstance. If the armature be placed exactly concentric within the bore of the poles, and the two or more magnetic fields be symmetrical about a line joining their centres, there is no tendency for the armature core to be drawn in one direction more than in another; but if there is any difference between the densities of the several fields, it will cause an unbalanced stress on the armature and its shaft, under which it will bend, and as this bending is continually reversed relatively to the fibres of the shaft, they will eventually become weakened and give way. Especially is this likely to take place in dynamos with short air-gaps, wherein any difference in the lengths of the air-gaps produces a much greater percentage difference in the flux-density than in dynamos with long air-gaps. In toothed armatures with short air-gaps the shaft must on this account be of great stiffness; even when the shaft is sufficiently strong to withstand the stress without appreciable bending, any unbalanced pull on the armature as a whole should be avoided, since it may produce greater friction in the bearings, and cause them to develop an undue amount of heat.

**The magnetic circuit.**

Reference has already been made to the importance in dynamo design of the *predetermination of the flux* due to a given number of ampere-turns wound on the field-magnet, or, conversely, of the number of ampere-turns which must be furnished by the exciting coils in order that a certain flux corresponding to one field may flow through the armature core from each pole. An equally important problem is the correct proportioning of the field-magnet, so that the useful flux $Z_a$ may be obtained with the greatest economy in materials and exciting energy. The key to the two problems is to be found in the concept of a magnetic circuit as originated by Rowland and Bosanquet;[1] and the full solution of both may be especially connected with the name of the late Dr J. Hopkinson, from his practical application of the concept in his design of the Edison-Hopkinson machine, and in his paper on "Dynamo-Electric Machinery."[2] The publication of this paper in 1886 begins the second era in the history of the dynamo; it at once raised its design from the level of empirical rules-of-thumb to a science, and is thus worthy to be ranked as the necessary supplement of the original discoveries of Faraday. The process of predetermining the necessary ampere-turns is described in a simple case under ELECTROMAGNET. In its extension to the complete dynamo, it consists merely in the division of the magnetic

[1] And extended by Kapp, "On Modern Continuous-Current Dynamo-Electric Machines," *Proc. Inst. C.E.* vol. lxxxiii. p. 136.

[2] Drs J. and E. Hopkinson, "Dynamo-Electric Machinery," *Phil. Trans.*, May 6, 1886; this was further expanded in a second paper on "Dynamo-Electric Machinery," *Proc. Roy. Soc.*, Feb. 15, 1892, and both are reprinted in *Original Papers on Dynamo-Machinery and Allied Subjects.*

circuit into such portions as have the same sectional area and permeability and carry approximately the same total flux; the difference of magnetic potential that must exist between the ends of each section of the magnet in order that the flux may pass through it, is then calculated *seriatim* for the several portions into which the magnetic circuit is divided, and the separate items are summed up into one magnetomotive force that must be furnished by the exciting coils.

The chief sections of the magnetic circuit are (1) the air-gaps, (2) the armature core, and (3) the iron magnet.

*The air-gap* of a dynamo is partly filled with copper and partly with the cotton, mica, or other materials used to insulate the core and inductors; all these substances are, however, sensibly non-magnetic, so that the whole interferric gap between the iron of the pole-pieces and the iron of the armature may be treated as an air-space, of which the permeability is constant for all values of the flux-density, and in the C.G.S. system is unity. Hence in the simple bipolar machine with single horse-shoe magnet, if $l_g$ and $A_g$ be the length and area of the single air-gap in cm. and sq.cm., the reluctance of the double air-gap is $\frac{2l_g}{A_g}$, and the difference of magnetic potential required to pass $Z_g$ lines over this reluctance is $Z_g \cdot \frac{2l_g}{A_g} = B_g \cdot 2l_g$; or, since one ampere-turn gives 1·257 C.G.S. units of magnetomotive force, the exciting power in ampere-turns required over the two air-gaps is $X_g = \frac{B_g \cdot 2l_g}{1{\cdot}257} = 0{\cdot}8\ B_g \cdot 2l_g$. In the determination of the area $A_g$ a small allowance must be made for the fringe of lines which extend beyond the actual polar face; and in the ring machine, as already mentioned, $Z_g$ is a few per cent. more than $Z_a$, owing to the leakage across the interior of the core.

In *the armature core* the length of path continually shortens as we pass from the middle of the pole towards the centre line of symmetry. On the other hand, as the lines gradually accumulate in the core, their density increases from zero midway under the poles until it reaches a maximum on the line of symmetry. The two effects partially counteract one another, and tend to equalize the difference of magnetic potential required over the paths of varying lengths; but since the reluctivity of the iron increases more rapidly than the density of the lines, we may approximately take for the length of path ($l_a$) the minimum peripheral distance between the edges of adjacent pole-faces, and then assume the maximum value of the density of the lines as holding throughout this entire path. In ring and drum machines the flux issuing from one pole divides into two halves in the armature core, so that the maximum density of lines in the armature is $B_a = \frac{Z_a}{2ab}$, where $a$ = the radial depth of the discs in centimetres and $b$ = the net length of iron core parallel to the axis of rotation. A distinction must be made between the gross length of the core and the net length of iron, owing to the waste of space through the insulating varnish or paper between the discs, and the presence of ventilating air-ducts, which are sometimes introduced at intervals along the length of the core, especially in multipolar armatures of large diameter. The former deduction may be said to average about 7 to 10 per cent. of the gross length. Reference has now to be made to a (B H) or flux-density curve, from which may be found the number of ampere-turns required per centimetre length of path. This may be expressed as a function of the assumed density $B_a$, and the total exciting power required between the pole-pieces is therefore, at no load, $X_p = X_g + X_a$, where $X_a = f(B_a) \cdot l_a$; in order, however, to allow for the effect of the armature current, which increases with the load, a further term $X_b$ must be added.

In the continuous-current dynamo it may be, and usually is, necessary to move the brushes forward from the interpolar line of symmetry through a small angle in the direction of rotation, in order to avoid sparking between the brushes and the commutator (*vide infra*). When the dynamo is giving current, the inductors on either side of the diameter of commutation form a current-sheet flowing along the surface of the armature from end to end, and whatever the actual end-connexions of the wires, the inductors may be imagined to be joined together into a system such that the two sides of each loop are carrying current in opposite directions. Thus a number of armature ampere-turns are formed, and their effect on the entire system of magnet and armature must be taken into account. So long as the diameter of commutation coincides with the line of symmetry, the armature may be regarded as a cylindrical electromagnet producing a flux of lines, as shown in Fig. 30. The direction of the self-induced flux in the air-gaps is the same as that of the lines of the external field in one quadrant on one side of DC, but opposed to it in the other quadrant on the same side of DC; hence in the resultant field due to the combined action of the field-magnet and armature ampere-turns, the flux is as much strengthened over the one half of each polar face as it is weakened over the other, and the total number of lines is unaffected, although their distribution is altered. The armature ampere-turns are then called *cross-turns*, since they produce a cross-field, which, when combined with the symmetrical field, causes the leading pole-corners $ll$ to be weakened and the trailing pole-corners $tt$ to be strengthened, the neutral line of zero field being thus twisted forwards in the direction of rotation.

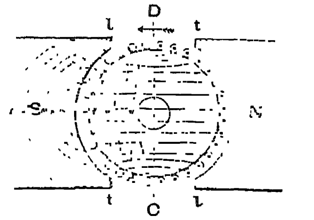

Fig. 30.

But when the brushes and diameter of commutation are shifted forward, as shown in Fig. 31, it will be seen that a number of ampere-turns, forming a zone between the lines D$n$ and $m$C, are in effect wound immediately on the magnetic circuit proper, and this belt of ampere-turns is in direct opposition to the ampere-turns of the field, as shown by the dotted and crossed wires on the pole-pieces.

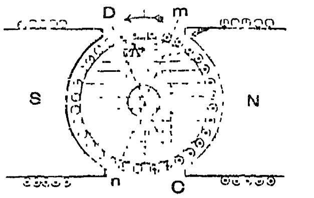

Fig. 31.

The armature ampere-turns are then divisible into the two bands, the *back-turns*, included within twice the angle of lead λ, weakening the field, and the cross-turns, bounded by the lines D$m$, $n$C, again producing distortion of the weakened symmetrical field. If, therefore, a certain flux is to be passed through the armature core in opposition to the demagnetizing turns, the difference of magnetic potential between the pole-faces must include not only $X_a$ and $X_g$, but also an item $X_b$, in order to balance the "back" ampere-turns of the armature. The amount by which the brushes must be shifted forward increases with the armature current, and in corresponding proportion the back ampere-turns are also increased, their value being $c \cdot \tau \cdot \frac{2\lambda}{360}$, where $c$ = the current carried by each of the $\tau$ inductors. Thus the term $X_b$ takes into account the effect of the armature reaction on the total flux; it varies as the armature current and angle of lead required to avoid sparking are increased; and the reason for its introduction in the third place ($X_p = X_g + X_a + X_b$), is that it increases the magnetic difference of potential which must exist between the poles of the dynamo, and to which the greater part of the leakage is due. The leakage paths which are in parallel with the armature across the poles must now be estimated, and so a new value be derived for the flux at the commencement of the *iron-magnet* path. If P = their joint permeance, the leakage flux due to the difference of potential at the poles is $z_{,} = 1{\cdot}257\ X_p \times P$, and this must be added to the useful flux $Z_g$, or $Z_p = Z_g + z_{,}$. There are also certain leakage paths in parallel with the magnet cores, and upon the permeance of these a varying number of ampere-turns is acting as we proceed along the magnet coils; the magnet flux therefore increases by the addition of leakage along the length of the limbs, and finally reaches a maximum near the yoke. Either, then, the density in the magnet $B_m = \frac{Z_m}{A_m}$ will vary if the same sectional area be retained throughout, or the sectional area of the magnet must itself be progressively increased. In general, sufficient accuracy will be obtained by assuming a certain number of additional leakage lines $z_{,,}$ as traversing the entire length of magnet limbs and yoke ($=l_m$), so that the density in the magnet has the uniform value $B_m = \frac{Z_p + z_{,,}}{A_m}$. The leakage flux added on actually within the length of the magnet core or $z_{,,}$ will be approximately equal to half the total M.M.F. of the coils multiplied by the permeance of the leakage paths around one coil. The corresponding value of H can then be obtained from the (B H) curve of the material of which the magnet is composed, and the ampere-turns thus determined must be added to $X_p$, or $X = X_p + X_m$, where $X_m = f(B_m) \cdot l_m$. The final equation for the exciting power required on the magnetic circuit as a whole will therefore take the form

$$X = AT = 0{\cdot}8B_g \cdot 2l_g + f(B_a) \cdot l_a + X_b + f(B_m) \cdot l_m \quad . \; . \; . \quad \text{(III.)}$$

Since no substance is impermeable to the passage of magnetic flux, the only form of magnetic circuit free from leakage is one uniformly wound with ampere-turns over its whole length. The reduction of the *magnetic leakage* to a minimum in any given type is therefore primarily a question of distributing the winding as far as

possible uniformly upon the circuit, and as the winding must be more or less concentrated into coils, it resolves itself into the necessity of introducing as long air-paths as possible between any surfaces which are at different magnetic potentials. No iron should be brought near the machine which does not form part of the magnetic circuit proper, and especially no iron should be brought near the poles, between which the difference of magnetic potential practically reaches its maximum value. In default of a machine of the same size or similar type on which to experiment, the probable direction of the leakage flux must be assumed from the drawing, and the air surrounding the machine must be mapped out into areas, between which the permeances are calculated as closely as possible by means of such approximate formulæ as those devised by Professor Forbes.[1]

***Magnetic leakage.***

***Excitation of field-magnet.***

In the earliest "magneto-electric" machines permanent steel magnets, either simple or compound, were employed, and for many years these were retained in certain alternators, some of which are still in use for arc lighting in lighthouses. But since the field they furnish is very weak, a great advance was made when they were replaced by soft-iron electromagnets, which could be made to yield a much more intense flux. As early as 1831 Faraday[2] experimented with electromagnets, and after 1850 they gradually superseded the permanent magnet. When the total ampere-turns required to excite the electromagnet have been determined, it remains to decide how the excitation shall be obtained; and, according to the method adopted, continuous-current machines may be divided into four well-defined classes.

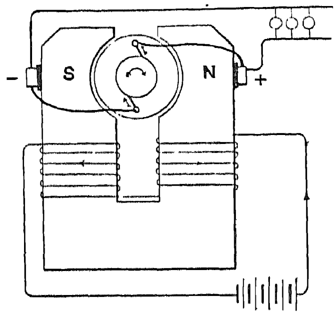

Fig. 32.

The simplest method, and that which was first used, is *separate excitation* from some other source of direct current, which may be either a primary or a secondary battery or another dynamo (Fig. 32). But since the armature yields a continuous current, it was early suggested (by Brett in 1848 and Sinsteden in 1851) that this current might be utilized to increase the flux; combinations of permanent and electromagnets were therefore next employed, acting either on the main armature or on separate armatures, until in 1867 Dr Werner von Siemens and Sir C. Wheatstone almost simultaneously discovered that the dynamo could be made *self-exciting* through the residual magnetism retained in the soft-iron cores of the electromagnet.[3] The former proposed to take the whole of the current round the magnet coils which were in series with the armature and external circuit, while the latter proposed to utilize only a portion derived by a shunt from the main circuit; we thus arrive at the second and third classes, namely, *series* and *shunt* machines. The starting of the process of excitation in either case is the same; when the brushes are touching the commutator and the armature is rotated, the small amount of flux left in the magnet is cut by the inductors, and a very small current begins to flow round the closed circuit; this increases the flux, which in turn further increases the E.M.F. and current, until, finally, the cumulative effect stops through the increasing saturation of the iron cores. Fig. 33, illustrating the *series* machine, shows the winding of the exciting coils to be composed of a few turns of thick wire. Since the current is undivided throughout the whole circuit, the resistance of both the armature and field-magnet winding must be low as compared with that of the external circuit, if the useful power available at the terminals of the machine is to form a large percentage of the total electrical power—in other words, if the efficiency is to be high. Fig. 34 shows the third

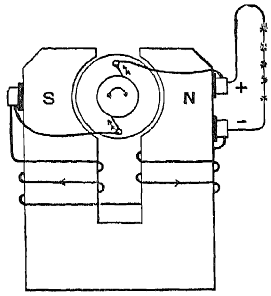

Fig. 33.

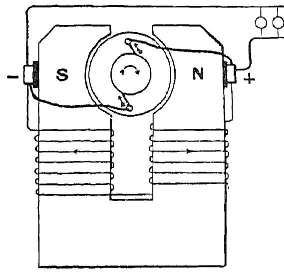

Fig. 34.

method, in which the winding of the field-magnets is a *shunt* or fine-wire circuit of many turns applied to the terminals of the machine; in this case the resistance of the shunt must be high[4] as compared with that of the external circuit, in order that only a small proportion of the total energy may be absorbed in the field.

Since the whole of the armature current passes round the field-magnet of the series machine, any alteration in the resistance of the external circuit will affect the excitation and also the voltage. A curve connecting together corresponding values of external current and terminal voltage for a given speed of rotation is known as the *external-characteristic* of the machine; in its main features it has the same appearance as a curve of magnetic flux, but when the current exceeds a certain amount, it begins to bend downwards and the voltage decreases. The reason for this will be found in the armature reaction at large loads, which gradually produces a more and more powerful demagnetizing effect, as the brushes are shifted forwards to avoid sparking; eventually the back ampere-turns overpower any addition to the field that would otherwise be due to the increased current flowing round the magnet. The "external characteristic" for a shunt machine has an entirely different shape. The field-magnet circuit being connected in parallel with the external circuit, the exciting current, if the applied voltage remains the same, is in no way affected by alterations in the resistance of the latter. As, however, an increase in the external current causes a greater loss of volts in the armature and a greater armature reaction, the terminal voltage, which is also the exciting voltage, is highest at no load and then diminishes. The fall is at first gradual, but after a certain critical value of the armature current is reached, the machine is rapidly demagnetized and loses its voltage entirely.

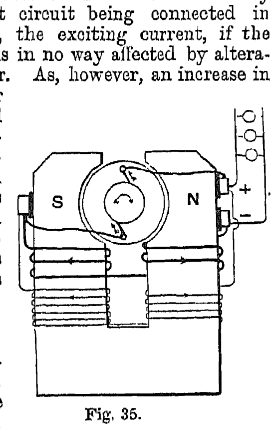

Fig. 35.

The last method of excitation, namely, *compound-winding* (Fig. 35), is a combination of the two preceding, and was first used by S. A. Varley[5] and by Brush. If a machine is in the first instance shunt-wound, and a certain number of series-turns are added, the latter, since they carry the external current, can be made to counteract the effect which the increased external current would have in lowering the voltage of the simple shunt machine. The ampere-turns of the series winding must be such that they not only balance the increase of the demagnetizing back ampere-turns on

[2] *Exp. Res.*, series i. § 4, par. 111. In 1845 Wheatstone and Cooke patented the use of "voltaic" magnets in place of permanent magnets (No. 10,655).

[3] In Pat. No. 3006, 1863, Wilde described the use of a small magneto-machine as exciter of a larger dynamo with electromagnets; cp. also his paper read before the Royal Society, April 1866. In 1866 C. and S. A. Varley provisionally protected a machine having electromagnets only, excited initially by the application of a direct current for a short time (No. 3394, 1866); this appeared again in the complete Patent No. 1755, 1867; but meantime the same device had been patented by Sir C. W. Siemens, Jan. 31, 1867, No. 261. Dr Werner von Siemens's paper was submitted to the Berlin Academy of Sciences, Jan. 1867 (*Pogg. Ann.*, Feb. 1867), and his results were communicated to the Royal Society in London by Sir William Siemens in a paper "On the Conversion of Dynamical into Electrical Force without the Aid of Permanent Magnetism," which was read on Feb. 14, 1867. On the same day Sir C. Wheatstone's paper "On the Augmentation of the Power of a Magnet by the Reaction thereon of Currents induced by the Magnet itself" was read before the Royal Society.

[4] Sir William Siemens, *Phil. Trans.*, part iii., 1880, "On the Dynamo-Electric Current, and on Certain Means to Improve its Steadiness," and Brit. Pat., No. 4534, 1879.

[5] In Brit. Pat., No. 4905, 1876, he describes a machine with its field-magnet wound with two coils of different resistance; and Brush (Brit. Pat., No. 2003, 1878) employed a shunt circuit to maintain the magnetism of a series-wound machine. But the full advantages of compound-winding were not realized until the patent of Crompton and Kapp (No. 4810, 1882).

the armature, but further increase the useful flux, and compensate for the loss of volts over their own resistance and that of the armature. The machine will then give for a constant speed a nearly constant voltage at its terminals, and the curve of the external characteristic becomes a straight line for all loads within its capacity. Since with most prime movers an increase of the load is accompanied by a drop in speed, this effect may also be counteracted; while, lastly, if the series-turns are still further increased, the voltage may be made to rise with an increasing load, and the machine is "over-compounded."

***Commutation and sparking.***

The question of the commutation [1] of the current in a section of the armature winding during the time when it is short-circuited by the brush resting simultaneously on both the trailing and leading sectors, turns primarily on the varying contact-resistance between the brush tip and the commutator sectors.[2] If the brushes are of the same width as the sectors, and T = the total time of the short-circuit depending on the speed of rotation, the area of contact between the brush and the leading sector at any time $t$ (reckoned from the commencement of short-circuit) is $\propto \frac{T-t}{T}$, while that between the brush and the trailing sector is $\propto \frac{t}{T}$; hence as the brush slides over from the leading to the trailing sector (Fig. 36), the contact-resistance of the leading sector gradually increases from $R_{\prime}$ to $\infty$, and at any time $t$ within the period of short-circuit is $R_{\prime} \cdot \frac{T}{T-t}$, while the contact-resistance of the trailing sector gradually diminishes from $\infty$ to $R_{\prime}$, and at any time is $R_{\prime}\frac{T}{t}$. If $c_1$ and $c_2$ be the instantaneous values of the current in the leading and trailing sectors respectively, the current densities $s_1$ and $s_2$ are $\propto \frac{c_1 T}{T-t}$ and $\frac{c_2 \cdot T}{t}$. If R = the resistance of the coil and its commutator connexions, and $f(t)$ be the E.M.F. induced in the coil by its rotation through the external field, either positive or negative according as it is moving on the trailing or leading side of the neutral line of zero field, the direction of the old current in the coil being reckoned as positive, the complete equation to the short circuit is by Kirchhoff's laws—

$$-L\frac{dc}{dt} + f(t) - Rc - \left(\frac{c_1}{T-t} + \frac{c_2}{t}\right) R\,T = 0.$$

Now when there is no induced E.M.F., or $f(t) = 0$—in other words, if the short-circuited section is moving in zero field—the current persists in the section by reason of its inductance, and does not fall in proportion to the amount by which the brush passes over on to the trailing sector; hence the current density of $c_1$ in the leading sector is greater than the density of $c_2$ in the trailing sector. There is thus a difference in the two values in the bracket, and $s_1$ being greater than $s_2$, there is a greater fall of potential between sector 1 and the brush than between sector 2 and the rest of the brush. Further, $c_2$ is negative, and the brush tip being necessarily throughout at the same potential, there results a potential difference acting round the circuit in the direction 1 – coil – 2, *i.e.*, against the positive decaying current of the coil, and assisting the current which is growing up in the trailing sector. Some part, therefore, of the self-induced E.M.F. is spent in overcoming this negative E.M.F. until equality is reached, and then the current becomes negative simply in virtue of the E.M.F. set up by the unequal current densities. If the equation as above expressed holds good unconditionally, and no secondary effects come into play, it will be found that the current in the short-circuited coil will be reversed to the exact value that is required in the new direction, or be automatically commuted at the end of the period of short-circuit by the mere action of the brush-contact resistance; and further, that this will be the case wherever the brush be placed, and whatever the direction

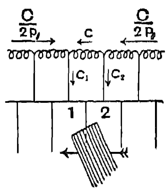

Fig. 36.

of the field in which the short-circuited coil is moving. If, however, it be moving in the old field, or $f(t)$ is positive, the current-density under the leading brush edge will be enormously great, in order to counterbalance both the E.M.F. of self-induction and that impressed by the field. There is, however, an important secondary effect, which comes into play when the current-density becomes very high, and which causes sparking at the brushes when the position of the brushes is not correctly adjusted. When a circuit is broken by an ordinary switch, the area of contact is diminished more or less rapidly, and when the current-density over the decreasing contact-surface rises beyond a certain limit, the local development of heat is so great that some portion of the metal forming the contact becomes incandescent and eventually is volatilized, and an arc results. In exactly the same way, under a very high current-density, the trailing edge of the leading sector or the leading edge of the brush becomes fused so that as the brush tip leaves the leading sector the current still finds an outlet for a short time through the heated vapour, and a series of small arcs are started every time that a sector passes from under the brush.

***Brushes.***

Now, in the dynamo, if the brushes are kept fixed on the line of symmetry, and current be taken out of the armature, the distribution of the field is so distorted by the action of the cross ampere-turns of the armature that the neutral line of zero field, where the lines just dip into the armature core and immediately leave it again, is displaced ahead of the line of symmetry. As the coil is now moving in the trailing field, the E.M.F. set up by it is in the old direction and tends to keep up the old current, hence the excessive current-density is magnified, and the more so as the current is increased. The higher the brush contact-resistance, however, the less the abnormal density, and the less the difficulty of commutation. One remedy, then, is to employ a brush of high contact-resistance, and for this purpose the only suitable material that has been discovered is carbon moulded into hard blocks. Even if some little sparking does take place with carbon brushes, the damage done thereby to the commutator surface is very much less than would be the case with metal brushes. The only objection to their use is that in virtue of their high resistance they necessarily increase the normal loss of volts between the armature winding and the external terminals. If brushes of copper wire or gauze are used, it is not possible to maintain them on the line of symmetry, when the current reaches any great amount, without excessive sparking, and the only remedy is to shift the brushes forward in the direction of rotation through an angle of lead, which increases roughly as the armature current is increased. By the shifting of the brushes the armature ampere-turns become divisible into the two groups of back- and cross-turns, as shown in Fig. 31. The latter are progressively reduced, so that though the total flux may not be so large as at no load, the distortion becomes less; and if the shifting is carried far enough, the diameter of commutation eventually overtakes the neutral line, and finally the short-circuited coil is moving in a reversing field, or $f(t)$ is negative. The reversing E.M.F. then rapidly causes the old current to decay, starts a reversed current, and if the adjustment is correct, the strength to which the new current is raised at the end of short-circuit is precisely that of the armature current in the portion of the winding which it is to join, so that on opening the short-circuit there is no sparking.

***Heating effects.***

From the moment that a dynamo begins to run with excited field, heat is continuously generated by the passage of the current through the windings of the field-magnet coils and the armature, as well as by the action of hysteresis and eddy-currents in the armature and pole-pieces. Whether the source of the heat be in the field-magnet or in the armature, the mass in which it originates will continue to rise in temperature until such a difference of temperature is established between itself and the surrounding air that the rate at which the heat is carried off by radiation, convection, and conduction is equal to the rate at which it is being generated. Evidently, then, the temperature which any part of the machine attains after a prolonged run must depend on the extent and effectiveness of the cooling surface from which radiation takes place, upon the presence or absence of any currents of air set up by the rotation of itself or surrounding parts, and upon the presence of neighbouring masses of metal to carry away the heat by conduction. In the field-magnet coils the rate at which heat is being generated is easily determined, since it is equal to the square of the current passing through them multiplied by their resistance. Further, the magnet is usually stationary, and only indirectly affected by draughts of air due to the rotating armature. Hence for machines of a given type and of similar proportions, it is not difficult to decide upon some method of reckoning the cooling surface of the magnet coils $S_c$, such that the rise of temperature above that of the surrounding air may be predicted from an equation of the form $t^{\circ} = \frac{k \cdot W}{S_c}$, where W = the rate in watts at

which heat is generated in the coils, and $k$ is some constant depending upon the exact method of reckoning their cooling surface. As a general rule the cooling surface of a field-coil is reckoned as equal to the exposed outer surface of its wire, the influence of the end flanges being neglected, or only taken into account in the case of very short bobbins wound with a considerable depth of wire. In the case of the rotating armature a similar formula must be constructed, but with the addition of a factor to allow for the increase in the effectiveness of any given cooling surface due to the rotation causing convection currents in the surrounding air. Only experiment can determine the exact effect of this, and even with a given type of armature it is dependent on the number of poles, each of which helps to break up the air-currents, and so to dissipate the heat. For example, in two-pole machines with drum bar-armatures, if the cooling surface be reckoned as equal to the cylindrical exterior plus the area of the two ends, the heating coefficient for a peripheral speed of 1500 feet per minute is less than half of that for the same armature when at rest. A further difficulty still meets the designer in the correct predetermination of the total loss of watts in an armature before the machine has been tested. It is made up of three separate items, namely, the copper loss in the armature winding, the loss by hysteresis in the iron, and the loss by eddy-currents, which again may be divided into those in the armature bars and end-connexions, and those in the core and its end-plates. The two latter items are both dependent upon the speed of the machine; but whereas the hysteresis loss is proportional to the speed for a given density of flux in the armature, the eddy-current loss is proportional to the square of the speed, and owing to this difference, the one loss can be separated from the other by testing an armature at varying speeds. Thus for a given rise of temperature, the question of the amount of current which can be taken out of an armature at different speeds depends upon the proportion which the hysteresis and eddy watts bear to the copper loss, and the ratio in which the effectiveness of the cooling surface is altered by the alteration in speed. Experimental data, again, can alone decide upon the amount of eddy-currents that may be expected in given armatures, and caution is required in applying the results of one machine to another in which any of the conditions, such as the width of the inductors, the number of poles, or the extent of lamination of the core, are altered.

It remains to add, that the rise of temperature which may be permitted in any part of a dynamo after a prolonged run is very generally placed at about 70° Fahr. above the surrounding air. Such a limit in ordinary conditions of working leads to a final temperature of about 170° Fahr., beyond which the durability of the insulation of the wires is liable to be injuriously affected. Upon some such basis the output of a dynamo in continuous working is rated, although for short periods of, say, two hours the normal full-load current of a large machine may be exceeded by some 25 per cent. without unduly heating the armature.

***Uses of continuous-current dynamos.***

For the electro-deposition of metals or the electrolytic treatment of ores a continuous current is a necessity; but, apart from such use, the purposes for which the continuous-current dynamo is well adapted are so numerous that they cover nearly the whole field of electrical engineering, with one important exception. To meet these various uses, the pressures for which the machine is designed are of equally wide range; for the transmission of power over long distances they may be as high as 3000 volts, and for electrolytic work as low as five. Each electrolytic bath, with its leads, requires on an average only some four or five volts, so that even when several are worked in series the voltage of the dynamo seldom exceeds 60. On the other hand, the current is large and may amount to as much as from 1000 to 14,000 amperes, necessitating the use of two commutators, one at either end of the armature, in order to collect the enormous current without excessive heating of the sectors and brushes. The field-magnets are invariably shunt-wound, in order to avoid reversal of the current through polarization at the electrodes of the bath. For incandescent lighting by glow lamps, the requirements of small isolated installations and of central stations for the distribution of electrical energy over large areas must be distinguished. For the lighting of a private house or large factory, the dynamo giving from 5 to 100 kilowatts of output is commonly wound for a voltage of 100, and is driven by pulley and belt from a gas, oil, or steam engine; or, if approaching the higher limit above mentioned, it is often directly coupled to the crank-shaft of the steam engine. If used in conjunction with an accumulator of secondary cells, it is shunt-wound, and must give the higher voltage necessary to charge the battery; otherwise it is compound-wound, in order to maintain the pressure on the lamps constant under all loads within its capacity. The compound-wound dynamo is likewise the most usual for the lighting of steamships, and is then directly coupled to its steam-engine; its output seldom exceeds 60 kilowatts, at a voltage ranging from 60 to 100. For central-station work, economy in the distributing mains dictates a higher voltage, especially in connexion with a three-wire system; the larger dynamos may then give 500 volts, and be connected directly across the two outer wires. A pair of smaller machines coupled together, and each capable of giving 250 volts, are often placed in series across the system, with their common junction connected to the middle wire; the one which at any time is on the side carrying the smaller current will act as a motor and drive the other as a dynamo, so as to balance the system. The directly-coupled steam dynamo may be said to have practically displaced the belt- or rope-driven sets which were formerly common in central stations. Though in Great Britain the bipolar machine has been generally retained for outputs up to 150 kilowatts, or even more, the tendency is towards the multipolar machine, which is largely used on the Continent and in the United States, even for comparatively small outputs. The generating units of the central station are arranged in progressive sizes, rising from, it may be, 250 or 500 horse-power up to 750 or 1000, or in large towns to as much as 5000 horse-power. They are usually shunt-wound, the regulation of the voltage, to keep the pressure constant on the distributing system under the gradual changes of load, being effected by variable resistances in the shunt circuit of the field-magnets.

Generators used for supplying current to electric tramways are commonly wound for 500 volts at no load and are over-compounded, so that the voltage rises to 550 volts at the maximum load, and thus compensates for the loss of volts over the transmitting lines. Since the changes of load are very rapid, it would not be possible to shift copper gauze brushes so that they should always be at the exact position to avoid sparking; hence carbon brushes are employed. For arc lighting it was formerly usual to employ a class of dynamo which, from the nature of its construction, was called an "open-coil" machine, and which gave a unidirected but pulsating current. Of such machines the Brush and Thomson-Houston types were very widely used; their E.M.F. ranged from 2000 to 3000 volts for working a large number of arcs in series, and by means of special regulators their current was maintained constant over a wide range of voltage. But as their efficiency was low and they could not be applied to any other purpose, they have been largely superseded in central stations by closed-coil dynamos or alternators, which can also be used for incandescent lighting. In cases where the central station is situated at some distance from the district to which the electric energy is to be supplied, voltages from 1000 to 2000 are employed, and these are transformed down at certain distributing centres by continuous-current transformers (see TRANSFORMERS and ELECTRICITY SUPPLY). These latter machines are in reality motor-driven dynamos, and hence are also called "*motor-generators*"; the armatures of the motor and dynamo are often wound on the same core, with a commutator at either end, the one to receive the high-pressure motor current, and the other to collect the low-pressure current furnished by the dynamo.

In all large central stations it is necessary that the dynamos should be capable of being run *in parallel*, so that their outputs may be combined on the same "omnibus bars," and thence distributed to the network or feeders. With simple shunt-wound machines this is easily effected by coupling together terminals of like sign when the voltage of the two or more machines are closely equal. With compound-wound dynamos not only must the external terminals of like sign be coupled together, but the junctions of the brush leads with the series winding must be connected by an "equalizing" lead of low resistance; otherwise, should the E.M.F. of one machine for any reason fall below the voltage of the omnibus bars, there is a danger of its polarity being reversed by a back current from the others with which it is in parallel.

Owing to the necessary presence in the continuous-current dynamo of the commutator, with its attendant liability to sparking at the brushes, and further, owing to the difficulty of insulating the rotating armature wires, a pressure of 3000 volts has seldom been exceeded in any one continuous-current machine, and has been given above as the limiting voltage of the class. If, therefore, it is required to work with higher pressures in order to secure economy in the transmitting lines, two machines must be coupled *in series* by connecting together two terminals which are of unlike sign. The stress of the total voltage may still fall on the insulation of the winding from the body of the machine; hence for high-voltage transmission of power over very long distances, the continuous-current dynamo must yield in convenience to the alternator. In this there is no commutator, the armature coils may be stationary and can be more thoroughly insulated, while further, if it be thought undesirable to design the machine for the full transmitting voltage, it is easy to wind the armature for a low pressure; this can be subsequently transformed up to a high pressure by means of the alternating-current transformer, which has stationary windings and so high an efficiency that but little loss arises from its use. With these remarks, the transition may be made to the fuller discussion of the alternator.

## ALTERNATORS.

**Value of K in E.M.F. equation.** The value of the factor K in the electromotive-force equation of the alternator (I. *b*) depends on the ratio of the pole-width to the pitch, and upon the distribution of the inductors of the coil; in the latter, two cases may be distinguished as "*grouped*" and "*uniform*" distribution. By the first, the coil is split up into two or more groups, each of these groups being itself so closely wound that its inductors may be regarded as in phase, although the several groups which are in series differ in phase.[1] By the second, the coil is uniformly wound over a certain portion of the periphery of the armature, as in Fig. 13. Thus the distinction of the two cases lies in the fact that with grouped distribution a small number of widely distinct phases are compounded together, while with uniform distribution a large number of phases differing very little from each other are united. In either case the result must be the same, namely, a reduction in the effective E.M.F. as compared with the same winding concentrated in a single line, since the several components are more or less out of phase. Yet the advantages are gained of a smaller inductance and a better ventilation of the armature conductors on the surface, and still more at the ends of the core. Further, the reduction in the E.M.F. only takes place in its full force at no load; when the armature is giving current its reaction on the field tends to crowd the lines towards one or other edge of each pole, and so to narrow the effective width of the pole-face. In actual machines the value of K usually falls between the limits of 1 and 1·25.[2]

**Shape of E.M.F. curve.** The first experimental determination of the shape of the E.M.F. curve of an alternator was made by Joubert in 1880. A revolving contact-maker charged a condenser with the E.M.F. produced by the armature at a particular instant during each period. The condenser was discharged through a ballistic galvanometer, and from the measured throw the instantaneous E.M.F. could be deduced. The contact-maker was then shifted through a small angle, and the instantaneous E.M.F. at the new position corresponding to a different moment in the period was measured; this process was repeated until the E.M.F. curve for a complete period could be traced. Various modifications of the same principle have since been used, and recently a form of "oscillograph" has been perfected which is well adapted for the purpose of tracing the curves both of E.M.F. and of current (see MEASURING INSTRUMENTS, ELECTRIC). The machine on which Joubert carried out his experiments was a Siemens disc alternator having no iron in its armature, and it was found that the curve of E.M.F. was practically identical with a sine curve. The same law has also been found to hold true for a smooth-core ring or drum armature, but the presence of the iron core enables the armature current to produce greater distorting effect, so that the curves under load may vary considerably from their shape at no load. In toothed armatures, the broken surface of the core, and the still greater reaction from the armature current, may produce wide variations from the sine law, the general tendency being to give the E.M.F. curve a more peaked form. The great convenience of the assumption that the E.M.F. obeys the sine law has led to its being very commonly used as the basis for the mathematical analysis of alternator problems; but any deductions made from this premiss require to be applied with caution if they are likely to be modified by a different shape of the curve. Further, the same alternator will give widely different curves even of E.M.F., and still more so of current, according to the nature of the external circuit to which it is connected. As will be explained later, the phase of the current relatively to the E.M.F. depends not only on the inductance of the alternator itself, but also upon the inductance and capacity of the external circuit, so that the same current will produce different effects according to the amount by which it lags or leads. The question as to the relative advantages of differently shaped E.M.F. curves has led to much discussion, but can only be answered by reference to the nature of the work that the alternator has to do—*i.e.*, whether it be arc lighting, motor driving, or incandescent lighting through transformers. The shape of the E.M.F. curve is, however, of great importance in one respect, since upon it depends the ratio of the maximum instantaneous E.M.F. to the effective value, and the insulation of the entire circuit, both external and internal, must be capable of withstanding the maximum E.M.F. While the maximum value of the sine curve is $\sqrt{2}$ or 1·414 times the effective value, the maximum value of a $\wedge$ curve is 1·732 times the effective value, so that for the same effective E.M.F. the armature wires must not only be more heavily insulated than in the continuous-current dynamo, but also the more peaked the curve, the better must be the insulation.

**Frequency.** The frequency employed in alternating-current systems for distributing power and light varies between such wide limits as 40 and 135; yet in recent times the tendency has been towards common standards of 50 and 60 or 100 as a maximum. High frequencies involve more copper in the magnet coils, owing to the greater number of poles, and a greater loss of power in their excitation, but the alternator as a whole is somewhat lighter, and the transformers are cheaper. On the other hand, high frequency may cause prejudicial effects, due to the inductance and capacity of the distributing lines; and in asynchronous motors used on polyphase systems the increased number of poles necessary to obtain reasonable speeds reduces their efficiency, and is otherwise disadvantageous, especially for small horse-powers. A frequency lower than 40 is, however, not permissible where arc lighting is to form any considerable portion of the work and is to be effected by the alternating current without rectification, since below this value the eye can detect the periodic alteration in the light as the carbons alternately cool and become heated. Thus for combined lighting and power 50 or 60 are the most usual frequencies; but if the system is designed solely or chiefly for the distribution of power, a still lower frequency is preferable, and on this account 25 was selected by the engineers for the Niagara Falls power transmission,[3] after careful consideration of the problem.

Each of the four methods of forming coils of many turns, namely, the ring, drum, discoidal ring, and disc, have already been shown to be applicable to alternators. *Ring*

[1] Such is the case of an armature having slots or holes evenly distributed round its periphery, each side of a drum coil or each complete ring coil being divided between two or more slots.

[2] Kapp, "Alternate-Current Machinery," *Proc. Inst. C.E.* vol. xcvii. part iii., 1888–89, and Elihu Thomson's remarks, p. 101; Parshall, *Engineering*, vol. lxv. p. 388; Fischer-Hinnen, *Elec. Eng.* vol. xx. p. 597; Brousson, *Electrical World*, 1895, vol. xxvi. p. 236.

[3] See Forbes, *Journ. Inst. Elec. Eng.* vol. xxii. p. 493.

*winding* (Fig. 13 i.) was early employed in the machines of Gramme and Wilde, and later of De Meritens. Owing to the excellent grip of the wires on the core, the ring coils are well adapted to withstand centrifugal force, and high peripheral speeds become permissible. The discoidal form of ring winding, with its appropriate form of field-magnet, may be easily derived from Figs. 13 ii. and 25. *Drum winding* in some of its numerous varieties is, however, more usual at the present time in alternators, as in continuous-current machines, and for the same reasons, namely, that it requires less wire and has less inductance. As in the continuous-current dynamo, the coils may be hand-wound, former-wound, or composed of bars united by end-connectors. If the armature core is smooth and the section of wire is small, the drum coil may be former-wound, and with a large number of poles the curvature required to fit it to the circumference of the armature core is so slight that it becomes almost flat; the open space within the inside turn is usually filled with a wood centre, flush with the sides. The complete coils may be placed either on the outside or inside of the armature core (Fig. 13 iii.), according as the poles are external or internal. A single coil per pair of poles may be used, as shown in Fig. 37, but the advantages of its division into two halves, as in Fig. 13 iii., namely, the better utilization of the space at the ends of the core and the gain in effective cooling surface, have already been mentioned. A pair of outside ends of adjacent coils and a pair of inside ends are then alternately connected together, and the maximum difference of potential between any two adjacent wires is equal to twice the voltage of one coil. But if the coils are all connected in series right round the armature, one of the groups, consisting of the adjacent halves of the first and last coils, is subjected to the strain of the total voltage; hence for high pressures it may be advantageous to insert one dummy coil to separate the first and last coils. Another plan is to divide the armature winding into two halves and to connect these in parallel, as in Fig. 38. Either circuit then carries half the current, but must give the total voltage of the machine, so that twice the number of inductors of half the section are required; there is thus a greater amount of space lost in insulation, and, as with all cases of parallel circuits, it is very necessary to secure close equality of the E.M.F.'s of the two branches at every instant, since otherwise the load will not divide equally between them, and a loss of efficiency, with greater heating, will result. As compared with ring winding, the drum coils on a rotating smooth core are not so easily held in place against centrifugal force and the alternating stresses due to the magnetic pull on them; the wood filling-pieces, being screwed to the core, serve as drivers, but with high peripheral speeds the surface must be covered at frequent intervals by bands of binding wire. It is therefore even more common to employ a toothed armature core, although the embedded wires have more inductance and more reaction on the field; the alternator then requires more alteration of its excitation if the voltage is to be kept constant under varying loads. When the slots of the armature have parallel sides, or the teeth do not close entirely over the opening at the top, the coils may still be wound on a former in the lathe, and afterwards pressed into the slot, which is well lined with micanite, press-spahn, or other highly-insulating material. But if the armature has holes pierced close to the periphery of the discs, hand-winding must be resorted to, and the wires are threaded through the holes in tubes of micanite or paper. The wires themselves must be well insulated, but do not need to be very tight in the holes, as by far the largest part of the mechanical pull is transferred to the iron core.

***Winding.***

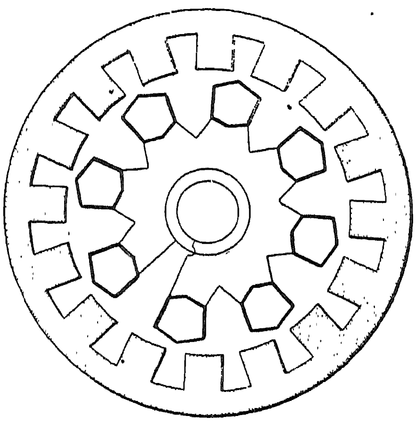

Fig. 37.

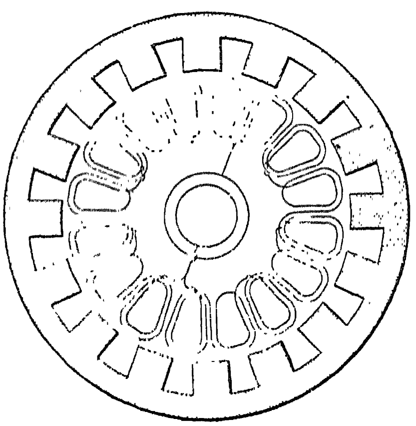

Fig 38.

*Disc winding* (Fig. 13 iv.) has been very successfully used for alternators, as in the large magneto-machines invented by Nollet, and afterwards constructed and improved by the Alliance Co. (1860), and also in the alternators of Wilde (1866) and Siemens (1878). The connexions of the coils can be followed from Figs. 37 and 38, which are as applicable to disc as to drum winding. It is usual for the armature to revolve, and no iron is employed in the core; there is therefore no loss from hysteresis, but a somewhat large exciting-current loss is involved by the length of the air-gap between the opposing poles of opposite sign. An undulatory winding which was adopted in some early alternators has since been discarded in favour of coils, as in Fig. 38. In the modern Ferranti alternator, the centres on which the coils are wound are made up of strips of brass soldered together at their inner ends and lightly insulated, to separate the teeth of the comb; eddy-currents in the core are thus largely prevented, and the advantage of a metal centre is retained. The thin copper strip employed in winding the coils is corrugated along its centre line, to retain it in its place and to prevent it shifting sideways. The very high peripheral speed which is used in this type of machine tends to keep the composite structure of the armature rigid in the plane of rotation.

***Quarter-phase alternators.***

The general idea of the polyphase alternator giving two or more E.M.F.'s of the same frequency, but displaced in phase, has been already described. The several phases may be entirely independent, and such was the case with the early polyphase machines of Gramme, who used four independent circuits, and also in the large two-phase alternators designed by Gordon in 1883. If the phases are thus entirely separate, each requires two collector rings and two wires to its external circuit, *i.e.*, four in all for two-phase, and six for three-phase, machines. The only advantage of the polyphase machine as thus used is that the whole of the surface of the armature core may be efficiently covered with winding, and the output of the alternator for a given size be thereby increased. It is, however, also possible so to interlink the several circuits of the armature that the necessary number of transmitting lines to the external circuits may be reduced, and also the weight of copper in them for a given loss in the transmission.[1] The condition which obviously must be fulfilled, for such interlinking of the phases to be possible, is that in the lines meeting at any common junction the algebraic sum of the instantaneous currents, reckoned as positive if away from such junction and as negative if towards it, must be zero. Thus if the phases be diagrammatically represented by the relative angular position of the coils in Fig. 39, the current in the coils

[1] As in the historical transmission of energy from Lauffen to Frankfort (1891).

A and B differs in phase from the current in the coils C and D by a quarter of a period, or 90°; hence if the two wires $b$ and $d$ be replaced by the single wire $bd$, this third wire will serve as a common path for the currents of the two phases either outwards or on their return. At any instant the value of the current in the third wire must be the vector sum of the two currents in the other wires, and if the shape of the curves of instantaneous E.M.F. and current are identical, and are assumed to be sinusoidal, the effective value of the current in the third wire will be the vector sum of the effective values of the currents in the other wires; in other words,

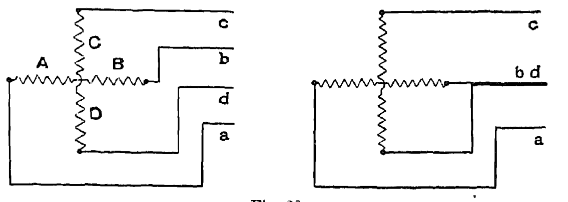

Fig. 39.

if the system is balanced, the effective current in the third wire is $\sqrt{2}$, or 1·414 times the current in either of the two outer wires. Since the currents of the two phases do not reach their maximum values at the same time, the sectional area of the third wire need not be twice that of the others; in order to secure maximum efficiency by employing the same current density in all three wires, it need only be 40 per cent. greater than that of either of the outer wires. The effective voltage between the external leads may in the same way be calculated by a vector diagram, and with the above *star connexion* the voltage between the outer pair of wires $a$ and $c$ is $\sqrt{2}$, or 1·414 times the voltage between either of the outer wires and the common wire $bd$. Next, if the four coils are joined up into a continuous helix, just as in the winding of a continuous-current machine, four wires may be attached to equidistant points at the opposite ends of two diameters at right angles to each other (Fig. 40). Such a method is known as the *mesh connexion*, and gives a perfectly symmetrical four-phase system of distribution. Four collecting rings are necessary if the armature rotates, and there is no saving in copper in the transmitting lines; but the importance of the arrangement lies in its use in connexion with rotary converters, in which it is necessary that the winding of the armature should form a closed circuit. If $e$ = the effective voltage of one

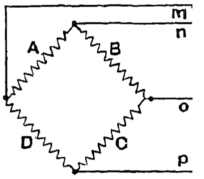

Fig. 40.

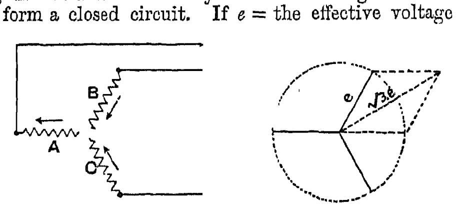

Fig. 41.

phase A, the voltage between any pair of adjacent lines in the diagram is $e$, and between $m$ and $o$ or $n$ and $p$ is $\sqrt{2}\,.\,e$. The current in any line is the resultant of the currents in the two phases connected to it, and its effective value is $\sqrt{2}\,.\,c$, where $c$ is the current of one phase.

**Three-phase alternators.**

When we pass to machines giving three phases differing by 120°, the same methods of star and mesh connexion find their analogies. If the current in coil A (Fig. 41) is flowing away from the centre, and has its maximum value, the currents in coils B and C are flowing towards the centre, and are each of half the magnitude of the current in A; the algebraic sum of the currents is therefore zero, and this will also be the case for all other instants. Hence the three coils can be united together at the centre, and three external wires are alone required. In this star or "Y" connexion, if $e$ be the effective voltage of each phase, or the voltage between any one of the three collecting rings and the common connexion, the volts between any pair of transmitting lines will be $E = \sqrt{3}\,.\,e$ (Fig. 41); if the load be balanced, the effective current C in each of the three lines will be equal, and the total output in watts will be $W = 3Ce = \frac{3CE}{\sqrt{3}} = 1{\cdot}732$ EC, or 1·732 times the product of the effective voltage between the lines and the current in any single line. Next, if the three coils are closed upon themselves in a mesh or *delta* fashion (Fig. 42), the three transmitting wires may be connected to the junctions of the coils (by means of collecting rings if the armature rotates). The voltage E between any pair of wires is evidently that generated by one phase, and the current in a line wire is the resultant of that in two adjacent phases; or in a balanced system, if $c$ be the current in each phase, the current in the line wire beyond a collecting ring is $C = \sqrt{3}\,.\,c$, hence the watts are $W = 3cE = \frac{3EC}{\sqrt{3}} = 1{\cdot}732$ EC, as before. Thus any three-phase winding may be changed over from the star to the delta connexion, and will then give 1·732 times as much current, but only 1/1·732 times the voltage, so that the output remains the same. Any of the alternator windings shown in previous diagrams are equally available for polyphase machines, if the width of the coils be altered to suit the number of phases.

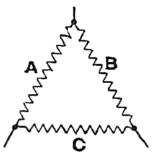

Fig. 42.

**Field-magnets.**

The field-magnet systems of alternators differ from those of continuous-current multipolar machines only in the employment of a larger number of pairs of poles;[1] hence the alternator usually has somewhat more copper in its exciting coils, and a slightly greater loss of watts in the excitation. Four of the most common types of field are shown in Fig. 13, and may be compared with Figs. 24 and 25. In Fig. 13 i. the armature rotates and is internal to the poles, while in Fig. 13 iii. it is stationary and external to the rotating poles; and it may be said that while in continuous-current dynamos it is most usual for the armature to rotate, in alternators it is more common for the magnet to rotate. The coils of the stationary armature, which for high voltages must be heavily insulated, are then not subjected to the additional stresses due to centrifugal force; and further, the collecting rings, which must be attached to the revolving portion, need only be employed to transmit the exciting current at a low voltage. The multipolar form of field-magnet with single exciting coil, shown in Fig. 29, has been very largely used for alternators, since its introduction by Mordey, with disc armature, and by the Oerlikon Co. of Switzerland in connexion with drum armatures; but although advantageous for particular frequencies and speeds, it requires careful designing to avoid a somewhat large armature reaction. A further step brings us to the so-called *inductor alternator*, in which both the armature and the field-magnet coils are stationary, and the E.M.F. is set up in the armature coils by causing the flux through them to be periodically varied by the rotation of iron "inductors." It will be seen that in Fig. 29 it is not really necessary for the field-magnet coil to revolve, and by such a modification as shown in Fig. 43 it can be held stationary, while the iron mass which completes the magnetic system is alone rotated. It is very important in such a machine to keep the reluctance of the magnetic circuit constant, so as to ensure as far as possible an equal flux in the magnet for all positions of the inductor; otherwise eddy-currents are set up in its mass. Even when the total flux alters but little, the pole-tips are usually laminated, owing to the variations in its distribution over their faces.

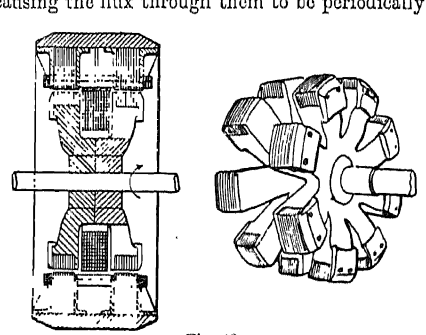

Fig. 43.

Since an alternating current cannot be used for exciting the field-magnet, recourse must be had to some source of a direct current. This is usually obtained from a small auxiliary continuous-current dynamo, called an *exciter*, which may be an entirely separate machine, separately driven and used for exciting several alternators, or may be driven from the alternator itself; in the latter case the armature of the exciter is often coupled directly to the rotating shaft of the alternator, while its field-magnet is attached to the bed-plate. Although separate excitation is the more usual method, the alternator can also be made self-exciting if a part or the whole of the alternating current is "rectified,"

[1] For experiments on high-frequency currents, Nikola Tesla constructed an alternator having 384 poles and giving a frequency of about 10,000 (*Journ. Inst. Elec. Eng.* vol. xxi. p. 82, 1892). The opposite extreme is found in alternators directly coupled to the Parsons steam turbine, in which, owing to its high speed of 3000 revs. per min., only four poles are required to give a frequency of 100. By a combination of a Parsons steam-turbine running at 12,000 revs. per min. with an alternator of 140 poles a frequency of 14,000 has been obtained (*Engineering*, Aug. 25, 1899).

and thus converted into a direct current. Or both methods may be employed simultaneously.

*Armature reaction.*

The reaction of the armature-current upon the field in an alternator is in many ways different from that of the continuous-current dynamo, and requires detailed consideration. Let a single-phase alternator be running on open circuit and giving a sine curve of E.M.F., and let a non-inductive resistance be applied to its terminals. At the instant of closing the circuit, a current arises, and in its growth causes a corresponding self-induced flux to arise, which as it cuts the armature coils generates an E.M.F. of self-inductance; this E.M.F. delays the rise of the current, so that its instantaneous value is not in step with the instantaneous value of the impressed E.M.F., although they gradually become more and more alike in phase. The first few waves of current are therefore distorted, their exact shape depending upon the moment in the period when the circuit is closed, and it is only after some little time that the current curve reaches its final shape and phase relatively to the impressed E.M.F. Since the impressed E.M.F. is always changing in value and never becomes steady, the current-phase can never overtake that of the E.M.F., but must continue to lag behind it by some angle of lag depending on the armature inductance. If the magnetic circuit presented to the armature coils had a constant inductance and no hysteresis, the self-induced flux would vary simultaneously with, and in proportion to, the current; both would be sinusoidal, and so also would be the E.M.F. of self-inductance, which would be in quadrature with either the flux or the current. The phase of the current with reference to the impressed E.M.F. would then be given by a simple vector diagram; since the armature current lags, the E.M.F. of self-inductance will be more than 90° behind the impressed E.M.F., and therefore will partially oppose it, so that the terminal E.M.F. will be less than the impressed E.M.F. minus the loss of volts over the armature resistance. The matter admits, however, of further analysis. The paths of the magnetic circuit presented to the armature coils vary according to the position of the coils relatively to the poles, and hence the reluctance to the self-induced flux is not constant, but varies. When the centre of a ring coil or the side of a drum coil is directly under a pole, all the ampere-turns of the coil act round a cross-circuit, or are *cross* ampere-turns, displacing the maximum density of the resultant field towards the trailing edges. As the coil moves forward, the self-induced flux divides, and some lines pass *through* a pair of field-magnet coils instead of across them. More strictly speaking, the ampere-turns are divisible now into cross and back ampere-turns, of which the latter directly reduce the strength of the symmetrical field, while the former simply distort the weakened symmetrical field. The proportion of back to cross turns gradually increases until the inductors of the coil are exactly mid way between the poles; later, as the coil passes under the next pole, and as soon as the current has reversed its direction, the armature turns become divisible into cross and *forward* ampere-turns. The latter increase the strength of the field, and their proportion relatively to the cross turns is continually increasing. Thus the effect of either the direct or the cross ampere-turns during a whole period can only be calculated by taking into account both the instantaneous values of the current and the magnetizing effect which a constant current would have for the different positions of the coil at corresponding instants. *E.g.*, if there were no difference of phase between current and impressed E.M.F., the dotted curve *mm* (Fig. 44) may be taken to represent the direct magnetizing effect of the coil in various positions for some constant value of current, say one ampere; the current curve being that marked *cc*, the product of simultaneous ordinates of the two curves may be plotted as *mc*, and will show the varying M.M.F. due to the direct ampere-turns, back ampere-turns being plotted below, and forward ampere-turns above, the base line. It is seen that in this case the periodic weakening and strengthening of the symmetrical field balances during a complete period, and the average flux is unaffected. Since, however, in our first case of an armature with self-inductance there must be some lag of current behind impressed E.M.F., Fig. 45 shows that the weakening effect lasts longer and is greater than the strengthening effect, so that the terminal E.M.F. for the same exciting current must decrease. Similarly, the cross flux will be found periodically to vary, or, in other words, the lines will be periodically crowded up into one or other pole-edge, and then resume their symmetrical distribution when either the current in the coil or its cross effect is zero. If there be lag of the current, the displacement towards the leading pole-edge will be less marked than that towards the trailing edge.

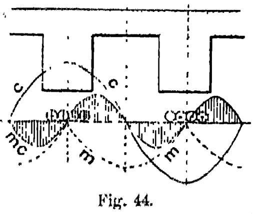

Fig. 44.

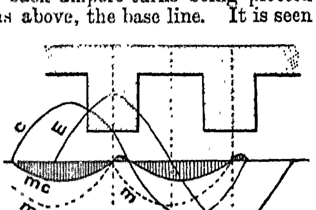

Fig. 45.

If the direct M.M.F. of the armature be taken into account in calculating the resultant flux, the smaller value of the self-induced E.M.F. which is then left simply measures the time-rate of change of the distortion, and has nothing to do with the strengthening and weakening of the field due to the lag or lead of the current. The importance of thus differentiating the armature reaction into the cross and direct magnetizing effect lies in the fact that, for a given terminal voltage under load, the actual density of lines in the magnet cores, for which allowance must be made in their sectional area, will be only that of the resultant flux due to the combined M.M.F. of the magnet winding and the direct ampere-turns. Since, however, both divisions of the armature reaction produce the same class of effect, they may be combined by assigning to the armature a certain inductance, which causes an E.M.F. of self-induction in quadrature with the current. It must then be remembered that the value of the flux corresponding to the impressed E.M.F. is really that which would be due to the same excitation if there were no armature current, and never really exists except at no load. If the external circuit also has self-inductance, the lag of the current is increased and the terminal voltage is further lowered. If, on the other hand, the external circuit has sufficient condenser capacity, the current may be brought back into phase with the E.M.F., or may even be in advance of it; in this case, the above effects are reversed, and the field and terminal E.M.F. are increased for the same exciting current.

Evidently, therefore, the characteristic curve connecting armature current and terminal volts with a constant exciting current depend on the nature of the load, whether inductive or non-inductive, and upon the amount of inductance already possessed by the armature itself. With an inductive load it will fall more rapidly from its initial maximum value, or, conversely, if the initial voltage is to be maintained under an increasing load, the exciting current will have to be increased more than if the load were non-inductive. In practical working many disadvantages result from a rapid drop of the terminal E.M.F. under increasing load, so that between no load and full load the variation in terminal voltage with constant excitation should not exceed 15 per cent. Thus the output of an alternator is limited either by its heating or by its armature reaction, just as is the output of a continuous-current dynamo; in the case of the alternator, however, the limit set by armature reaction is not due to any sparking at the brushes, but to the drop in terminal voltage as the current is increased, and the consequent difficulty in maintaining a constant potential on the external circuit.

***The coupling of alternators.***

The joint operation of several alternators so that their outputs may be delivered into the same external circuit, is sharply distinguished from the corresponding problem in continuous-current dynamos by the necessary condition that they must be in synchronism—*i.e.*, not only must they be so driven that their frequency is the same, but their E.M.F.'s must be in phase or, as it is also expressed, the machines must be *in step*. Although in practice it is impossible to run two alternators in series unless they are rigidly coupled together—which virtually reduces them to one machine—two or more machines can be run in parallel, as was first described by Wilde in 1868, and subsequently redemonstrated by Hopkinson and Adams in 1884. Their E.M.F.'s should be as nearly as possible in synchronism, but as contrasted with series connexion, parallel coupling gives them a certain power of recovery if they fall out of step, or are not in exact synchronism when thrown into parallel. Under such circumstances a synchronizing current passes between the two machines, due to the difference in their instantaneous pressures; and as this current agrees in phase more nearly with the leading than with the lagging machine, the former machine does work as a generator on the latter as a motor. Hence the lagging machine is accelerated and the leading machine is retarded, until their frequencies and phase are again the same.

***Uses of alternators.***

The chief use of the alternator has already been alluded to. Since it can be employed to produce very high pressures either directly or through the medium of transformers, it is specially adapted to the electrical transmission of energy over long distances.[1] In the early days of electric lighting, the alternate-current system was adopted for a great number of central stations, the machines, designed to

[1] In the pioneer three-phase transmission between Lauffen and Frankfort (*Electrician*, vol. xxvi. p. 637, and xxvii. p. 548), the three-phase current was transformed up from about 55 to 8500 volts, the distance

give a pressure of 2000 volts, supplied transformers which were situated at considerable distances and spread over large areas, without an undue amount of copper in the transmitting lines. While there was later a tendency to return to the continuous current for central stations, owing to the introduction of better means for economizing the weight of copper in the mains, the alternating current is again coming into favour in special cases, as rendering it possible to place the central station in some convenient site far away from the district which it is to serve. The pioneer central station in this direction was the Deptford station of the London Electric Supply Corporation, which furnished current to the heart of London from a distance of 7 miles. In this case, however, the alternators were single-phase and gave the high pressure of 10,000 volts immediately, while more recently the tendency has been to employ step-up transformers and a polyphase system.[1] The advantage of the latter is that the current, after reaching the distant sub-stations, can be dealt with by rotary converters, through which it is transformed into a continuous current. The alternator is also used for welding, smelting in electric furnaces, and other metallurgical processes where heating effects are alone required; the large currents needed therein can be produced without the disadvantage of the commutator, and, if necessary, transformers can be interposed to lower the voltage and still further increase the current. The alternating system can thus meet very various needs, and its great recommendation may be said to lie in the flexibility with which it can supply electrical energy through transformers at any potential, or through rotary converters in continuous-current form.

being 110 miles. Between Eichdorf and Grünberg, energy developed at 225 volts is transmitted after transformation up to 10,000 volts (*Electrician,* vol. xxxviii. p. 469, 1897); while in the transmission from Paderno to Milan the three-phase current is generated directly at 13,500 volts (*Elettricità,* vol. xvii. p. 133, 1898). At Kootenay-Rossland the three-phase current is transformed up from 1100 to 20,000 volts.

**Dynamometers.**—If P represent the average value of the component of a force in the direction of the displacement, $s$, of its point of application, the product P$s$ measures the work done during the displacement. When the force acts on a body free to turn about a fixed axis only, it is convenient to express the work done by the transformed product T$\theta$, where T is the average turning moment or torque acting to produce the displacement $\theta$ radians. A dynamometer is used in the process of measuring work to measure the force P, or the torque T. The factors $s$ or $\theta$ are observed independently. Apparatus is added to some dynamometers by means of which a curve showing the variations of P on a distance base is drawn automatically, the area of the diagram representing the work done; with others, integrating apparatus is combined, from which the work done during a given interval may be read off directly. It is convenient to distinguish between absorption and transmission dynamometers. In the first kind the work done is converted into heat; in the second it is transmitted, after measurement, for use.

*Absorption Dynamometers.*—Prony's dynamometer (*Ann. Chim. Phys.* vol. xix., Paris, 1821), which has been modified in various ways, consists in its original form of two symmetrically-shaped timber beams clamped to the engine-shaft. When these are held from turning, their frictional resistance may be adjusted by means of nuts on the screwed bolts which hold them together until the shaft revolves at a given speed. To promote smoothness of action, the rubbing surfaces are lubricated. A weight is moved along the arm of one of the beams until it just keeps the brake steady, midway between the stops which must be provided to hold it when the weight fails to do so. The general theory of this kind of brake is as follows:—Let F be the whole frictional resistance, $r$ the common radius of the rubbing surfaces, W the force which holds the brake from turning and whose line of action is at a perpendicular distance R from the axis of the shaft, N the revolutions of the shaft per minute, $\omega$ its angular velocity in radians per second; then, assuming that the adjustments are made so that the engine runs steadily at a uniform speed, and that the brake is held still, clear of the stops, and without oscillation, by W, the torque T exerted by the engine is equal to the frictional torque F$r$ acting at the brake surfaces, and this is measured by the statical moment of the weight W about the axis of revolution; that is—

$$T = Fr = WR \quad . \quad . \quad . \quad . \quad (1)$$

Hence WR measures the torque T.

If more than one force be applied to hold the brake from turning, F$r$, and therefore T, are measured by the algebraical sum of their individual moments with respect to the axis. If the brake is not balanced, its moment about the axis must be included. Therefore, quite generally,

$$T = \Sigma WR \quad . \quad . \quad . \quad . \quad . \quad (2)$$

The factor $\theta$ of the product T$\theta$ is found by means of a revolution counter. The power of a motor is measured by the rate at which it works, and this is expressed by $T\omega = \frac{T 2\pi N}{60}$ in foot-pounds per second, or $\frac{T 2\pi N}{33,000}$ in horse-power units. The latter is commonly referred to as the brake horse-power. The maintenance of the conditions of steadiness implied in equation (1) depends upon the constancy of F, and therefore of the coefficient of friction $\mu$ between the rubbing surfaces. The heating at the surfaces, the variations in their smoothness, and the variations of the lubrication make $\mu$ continuously variable, and necessitate frequent adjustment of W or of the nuts. Poncelet invented a form of Prony brake which automatically adjusted its grip as $\mu$ changed, thereby maintaining F constant.

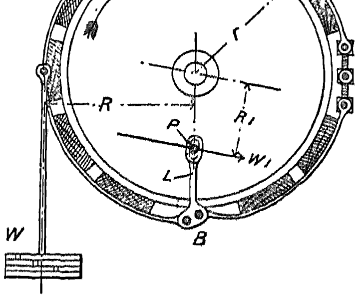

Fig. 1.

The principle of the Appold compensating brake is shown in Fig. 1. A flexible steel band, lined with wood blocks, is

gripped on the motor fly-wheel or pulley by a screw A, which, together with W, is adjusted to hold the brake steadily. Compensation is effected by the lever L inserted at B. This has a slotted end, engaged by a pin P fixed to the framing, and it will be seen that its action is to slacken the band if the load tend to rise and to tighten it in the contrary case. The external forces holding the brake from turning are W, distant R from the axis, and the reaction, $W_1$ say, of the lever against the fixed pin P, distant $R_1$ from the axis. The moment of $W_1$ may be positive or negative. The torque T at any instant of steady running is therefore $\{WR \mp W_1R_1\}$.

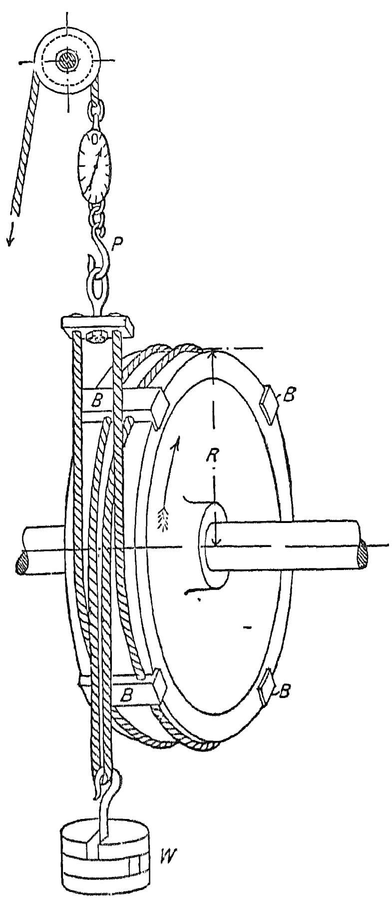

Fig. 2.

Lord Kelvin patented a brake in 1858 (Fig. 2) consisting of a rope or cord wrapped round the circumference of a rotating wheel, to one end of which is applied a regulated force, the other end being fixed to a spring balance. The ropes are spaced laterally by the blocks B, B, B, B, which also serve to prevent them from slipping sideways. When the wheel is turning in the direction indicated, the forces holding the band still are W, and $p$, the observed pull on the spring balance. Both these forces usually act at the same radius R, the distance from the axis to the centre line of the rope, in which case the torque T is $(W-p)R$, and consequently the brake horse-power is $\frac{(W-p)R\times 2\pi N}{33,000}$. When $\mu$ changes the weight W rises or falls against the action of the spring balance until a stable condition of running is obtained. The ratio $\frac{W}{p}$ is given by $e^{\mu\theta}$, where $e=2{\cdot}718$ : $\mu$ is the coefficient of friction and $\theta$ the angle, measured in radians, subtended by the arc of contact between the rope and the wheel. In Fig. 2 $\theta=2\pi$. This ratio increases very rapidly as $\theta$ is increased, and therefore by making $\theta$ sufficiently large, $p$ may conveniently be made a small fraction of W, thereby rendering errors of observation of the spring balance negligible. Thus this kind of brake, though cheap to make, is, when $\theta$ is large enough, an exceedingly accurate measuring instrument, readily applied and easily controlled. It has come into very general use in recent years, and has practically superseded the older forms of block brakes.

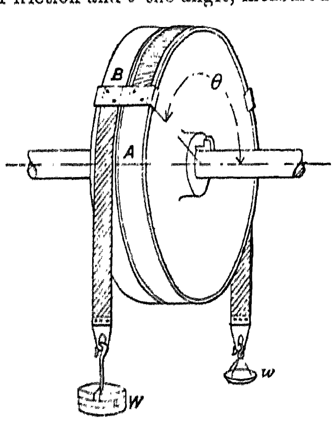

Fig. 3.

It is sometimes necessary to use water to keep the brake wheel cool. Engines specially designed for testing are usually provided with a brake wheel having a trough-shaped rim. Water trickles continuously into the trough, and the centrifugal action holds it as an inside lining against the rim, where it slowly evaporates.

Fig. 3 shows a band-brake invented by Professor James Thomson, suitable for testing motors exerting a constant torque (see *Engineering*, 22nd October 1880). To maintain $e^{\mu\theta}$ constant, compensation for variation of $\mu$ is made by inversely varying $\theta$. A and B are fast and loose pulleys, and the brake band is placed partly over the one and partly over the other. Weights W and $w$ are adjusted to the torque. The band turns with the fast pulley if $\mu$ increase, thereby slightly turning the loose pulley, otherwise at rest, until $\theta$ is adjusted to the new value of $\mu$. This form of brake was also invented independently

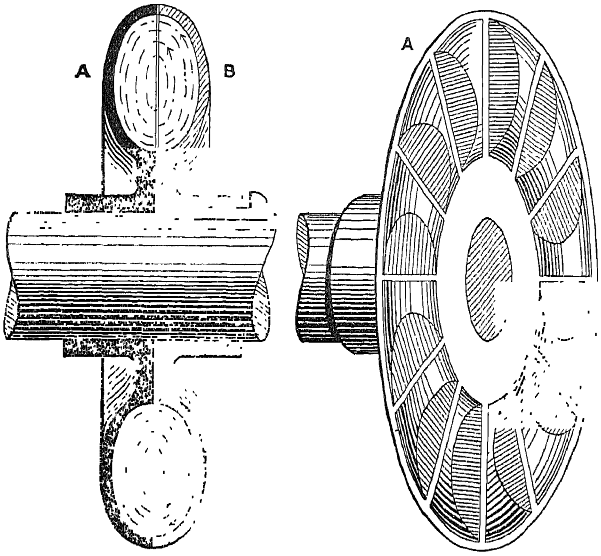

Fig. 4

by Carpentier, and the principle has been used in the Raffard brake. A self-compensating brake of another kind, by Marcel Deprez, was described with Carpentier's in 1880 (*Bulletin de la Société d'Encouragement*, Paris). Ayrton and Perry have used a band or rope brake in which compensation is effected by the pulley drawing in or letting out a part of the band or rope which has been roughened or in which a knot has been tied.

In an effective water-brake invented by W. Froude (see *Proc. Inst. M. E.*, 1877), two similar castings, A and B, each consisting of a boss and circumferential annular channel, are placed face to face on a shaft, to which B is keyed, A being free (Fig. 4). A ring tube of elliptical section is thus formed. Each channel is divided into a series of pockets by equally spaced vanes inclined at 45°. When A is held still and B rotated, centrifugal action sets up vortex currents in the water in the pockets; thus a continuous circulation is caused between B and A, and the consequent changes of momentum give rise to oblique reactions. The moments of the components of these actions and reactions in a plane to which the axis of rotation is at right angles are the two aspects of the torque acting, and therefore the torque acting on B through the shaft is measured by the torque required to hold A still. Froude constructed a brake to take up 2000 H.P. at 90 revs. per min. by duplicating this apparatus. This replaced the propeller of the ship whose engines were to be tested, and the outer casing was held from turning by a suitable arrangement of levers carried to weighing apparatus conveniently disposed on the wharf. The torque corresponding to 2000 H.P. at 90 revs. per min. is 116,772 foot-pounds, and a brake 5 feet in diameter gave this resistance. Thin metal sluices were arranged to slide between the wheel and casing, and by their means the range of action could be varied from 300 H.P. at 120 revs. per min. to the maximum.

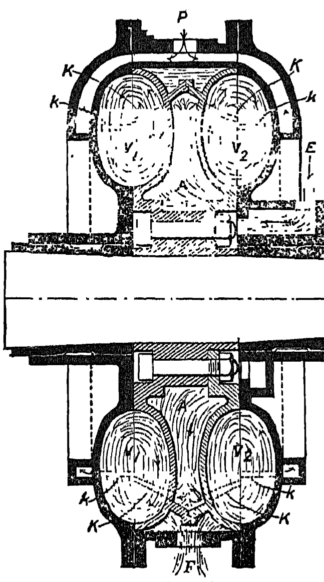

Fig. 5.

Professor Osborne Reynolds in 1887 patented a water-brake (see *Proc. Inst. C. E.* vol. xcix. p. 167), using Froude's turbine to obtain the highly resisting spiral vortices, and arranging passages in the casing for the entry of water at the hub of the wheel and its exit at the circumference. Water enters at E (Fig. 5), and finds its way into the interior of the wheel, A, driving the air in front of it through the air-passages K, K. Then following into the pocketed chambers $V_1$, $V_2$, it is caught into the vortex, and finally escapes at the circumference, flowing away at F. The air-ways *k*, *k*, in the fixed vanes establish communication between the cores of the vortices and the atmosphere. From $\frac{1}{2}$ to 30 H.P. may be measured at 100 revs. per min. by a brake-wheel of this kind 18 inches in diameter. For other speeds the power varies as the cube of the speed. The casing is held from turning by weights hanging on an attached arm. The cocks regulating the water are connected to the casing, so that any tilting automatically regulates the flow, and therefore the thickness of the film in the vortex. In this way the brake may be arranged to maintain a constant torque, notwithstanding variation of the speed. In Alden's brake (see *Trans. Amer. Soc. Eng.* vol. xi.) the resistance is obtained by turning a cast-iron disc against the frictional resistance of two thin copper plates, which are held in a casing free to turn upon the shaft, and are so arranged that the pressure between the rubbing surfaces is controlled, and the heat developed by friction carried away, by the regulated flow of water through the casing. The torque required to hold the casing still against the action of the disc measures the torque exerted by the shaft to which the disc is keyed.

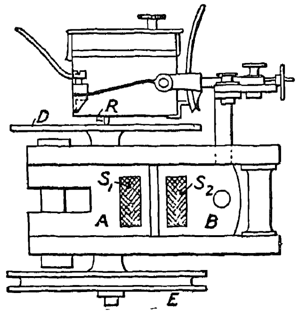

Fig. 6.

*Transmission Dynamometers.*—The essential part of many transmission dynamometers is a spring whose deformation indirectly measures the magnitude of the force transmitted through it. For many kinds of spring the change of form is practically proportional to the force, but the relation should always be determined experimentally. Morin (see *Notice sur divers appareils dynamométriques*, Paris, 1841), in his classical experiments on traction, arranged his apparatus so that the change in form of the spring was continuously recorded on a sheet of paper drawn under a style. For longer experiments he used a "Compteur" or mechanical integrator, suggested by Poncelet, from which the work done during a given displacement could be read off directly. This device consists of a roller of radius *r*, pressed into contact with a disc. The two are carried on a common frame, so arranged that a change in form of the spring causes a relative displacement of the disc and roller, the point of contact moving radially from or towards the centre of the disc. The radial distance *x* is at any instant proportional to the force acting through the spring. The angular displacement, $\theta$, of the disc is made proportional to the displacement, *s*, of the point of application of the force by suitable driving gear. If $d\phi$ is the angular displacement of the roller corresponding to displacements, $d\theta$ of the disc, and $ds$ of the point of application of P, *a*, and C constants, then $d\phi=\frac{xd\theta}{r}=\frac{a}{r}\mathrm{P}ds=\mathrm{C.P}ds$, and therefore $\phi=\mathrm{C}\int_{s_1}^{s_2}\mathrm{P}ds$; that is, the angular displacement of the roller measures the work done during the displacement from $s_1$ to $s_2$. The shaft carrying the roller is connected to a counter so that $\phi$ may be observed. The angular velocity of the shaft is proportional to the rate of working. Morin's dynamometer is shown in Fig. 6. The transmitting spring is made up of two flat bars linked at their ends. Their centres $s_1$, $s_2$, are held respectively by the pieces A, B, which together form a sliding pair. The block A carries the disc D, B carries the roller R and counting gear. The pulley E is driven from an axle of the carriage. In a dynamometer used by Mr F. W. Webb to measure the tractive resistance of trains on the London and North-Western Railway, a tractive pull or push compresses two spiral springs by a definite amount, which is recorded to scale by a pencil on a sheet of paper, drawn continuously from a storage drum at the rate of three inches per mile, by a roller driven from one of the carriage axles. Thus the diagram shows the tractive force at any instant. A second pencil electrically connected to a clock traces a time line on the diagram with a kick at every thirty seconds. A third pencil traces an observation line in which a kick can be made at will by pressing any one of the electrical pushes placed about the car, and a fourth draws a datum line. The spring of the dynamometer car used by Mr Dean on the Great Western Railway is made up of thirty flat plates, 7 ft. 6 in. long, 5 in. × $\frac{5}{8}$ in. at the centre, spaced by distance pieces nibbed into the plates at the centre and by rollers at the ends. The drawbar is connected to the buckle, which is carried on rollers, the ends of the spring resting on plates fixed to the under-frame. The gear operating the paper roll is driven from the axle of an independent wheel which is let down into contact with the rail when required. This wheel serves also to measure the distance travelled. A Morin disc and roller integrator is connected with the apparatus, so that the work done during a journey may be read off. Five lines are traced on the diagram.

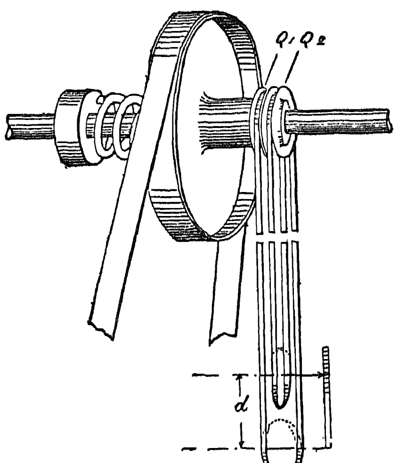

Fig. 7.

In spring dynamometers designed to measure a transmitted torque, the mechanical problem of ascertaining the change of form of the spring is complicated by the fact that the spring and the whole apparatus are rotating together. In the Ayrton and Perry transmission dynamometer or spring coupling of this type, the relative angular displacement is proportional to the radius of the circle described by the end of a light lever operated by mechanism between the spring-connected parts. Prof. Dalby (see *Proc. Inst. C. E.* vol. cxxxii., 1897–98) uses a device shown in Fig. 7, by means of which the change in form of the spring is shown on a fixed indicator, which may be placed in any convenient position. Two equal sprocket wheels $Q_1$, $Q_2$, are fastened, the one to the spring pulley, the other to the shaft. An endless band is placed over them to form two loops, which during rotation remain at the same distance apart, unless relative angular displacement occurs between $Q_1$ and $Q_2$, due to a change in form of the spring. The change in the distance *d* is proportional to the change in the torque transmitted from the shaft to the pulley. To measure this, guide pulleys are placed in the loops guided by a geometric slide, the one pulley carrying a scale, and the other an index. A recording drum or integrating apparatus may be arranged on the pulley frames. A quick variation, or a periodic variation of the magnitude of the force or torque transmitted through the springs, tends to set up oscillations, and this tendency increases the nearer the periodic time of the force variation approaches a periodic time of the spring. Such vibrations may be damped out to a considerable extent by the use of a dash-pot, or may be practically prevented by using a relatively stiff spring.

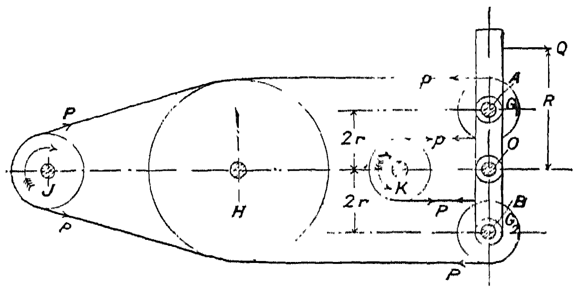

Fig. 8.

Every part of a machine transmitting force suffers elastic deformation, and the force may be measured indirectly by measuring the deformation. The relation between the two should in all cases be found experimentally. Hirn (see *Les Pandynamomètres*, Paris, 1876) employed this principle to measure the torque transmitted by a shaft. Signor Rosio used a telephonic method to effect the same end, and more recently mechanical, optical, and telephonic devices have been utilized by the Rev. F. J. Jervis-Smith. (See *Phil. Mag.*, Feb. 1898.)

When a belt in which the maximum and minimum tensions are respectively *P* and *p* lb, drives a pulley, the torque exerted is $(\mathrm{P}-p)r$ lb ft., *r* being the radius of the pulley plus half the thickness of the belt. P and *p* may be measured directly by leading the belt round two freely hanging guide pulleys,

one in the tight, the other in the slack part of the belt, and adjusting loads on them until a stable condition of running is obtained. In W. Froude's belt dynamometer (see *Proc. Inst. M.E.*, 1858) (Fig. 8) the guide pulleys $G_1$, $G_2$ are carried upon an arm free to turn about the axis O. H is a pulley to guide the approaching and receding parts of the belt to and

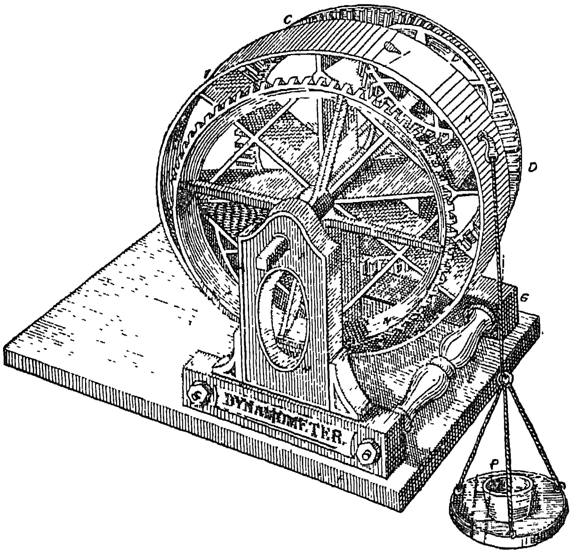

Fig. 9.

from the beam in parallel directions. Neglecting friction, the unbalanced torque acting on the beam is $4r\{P-p\}$ lb ft. If a force Q acting at R maintains equilibrium, $\frac{QR}{4}=(P-p)r=T$. Q is supplied by a spring, the extensions of which are recorded on a drum driven proportionally to the angular displacement of the driving pulley; thus a work diagram is obtained. Farcot has designed a form in which the guide pulleys are attached to separate weighing levers placed horizontally below the apparatus. In a belt dynamometer built for the Franklin Institute from the designs of Mr Tatham, the weighing levers are separate and arranged horizontally at the top of the apparatus. The weighing beam in the Hefner-Alteneck dynamometer is placed transversely to the belt (see *Electrotechnischen Zeitschrift*, Heft 7, 1881). The force Q, usually measured by a spring, required to maintain the beam in its central position is proportional to $(P-p)$. If the angle $\theta_1=\theta_2=120°$, $Q=(P-p)$ neglecting friction.

When a shaft is driven by means of gearing the driving torque is measured by the product of the resultant pressure P acting between the wheel teeth and the radius of the pitch circle of the wheel fixed to the shaft. Fig. 9, which has been reproduced from J. White's *A New Century of Inventions* (Manchester, 1822), illustrates possibly the earliest application of this principle to dynamometry. The wheel D, keyed to the shaft overcoming the resistance to be measured, is driven from wheel N by two bevel wheels L, L, carried in a loose pulley K. The two shafts, though in a line, are independent. A torque applied to the shaft A can be transmitted to D, neglecting friction, without change only if the central pulley K is held from turning; the torque required to do this is twice the torque transmitted.

The torque acting on the armature of an electric motor is necessarily accompanied by an equal and opposite torque acting on the frame. If, therefore, the motor is mounted on a cradle free to turn about knife-edges, the reacting torque is the only torque tending to turn the cradle when it is in a vertical position, and may therefore be measured by adjusting weights to hold the cradle in a vertical position. The rate at which the motor is transmitting work is then $\frac{T2\pi n}{550}$ H.P., where $n$ is the revolutions per second of the armature.

"Ueber Bremsdynamometer und verwandte Kraftmesser," *Zeitschrift des Vereins deutscher Ingenieure.* Berlin, 1888.—FLATHER, J. J. *Dynamometers and the Measurement of Power.* New York, 1893.

(W. E. D.)

**Dzungaria** or **Jungaria,** the name that may conveniently be given to the broad trench leading from the Mongolian plateau to the lowlands round Lake Balkhash, and limited by the Eastern Altai in the north and the Eastern Tian-shan in the south. It was formerly an independent state, and has played an important part in the history of Mongolia and the great migrations of Mongolian stems westward. Now its territory belongs partly to the Chinese Empire (East Turkestan and North-Western Mongolia) and partly to Russian Turkestan (provinces of Semiryechensk and Semipalatinsk). See MONGOLIA and EAST TURKESTAN.

---

**Eads, James Buchanan** (1820–1887), American engineer, was born at Lawrenceburg, Indiana, on 23rd May 1820. His first engineering work of any importance was in raising sunken steamers. In 1845 he established glass works in St Louis. During the Civil War he constructed ironclad steamers and mortar boats for the Federal Government. His next important engineering achievement was the construction of the great steel arch bridge across the Mississippi at St Louis (see *Encyclopædia Britannica*, vol. xxi. p. 185), upon which he was engaged from 1867 till 1874. The work, however, upon which his reputation principally rests was his deepening and fixing the channel at the mouths of the Mississippi by means of jetties, whereby the narrowed stream was made to scour out its own channel and carry the sediment out to sea. (See vol. xx. pp. 580, 581.) Shortly before his death he projected a scheme for a ship railway across the Isthmus of Tehuantepec, in lieu of an isthmian canal. He died at Nassau, in the Bahamas, on 8th March 1887.

**Eaglehawk,** a borough of Victoria, Australia, in the county of Bendigo, 4 miles north-north-west of Bendigo city, with which it is connected by steam tramway. It has a fine park, with lake, of 40 acres. There are valuable gold mines in the district. Altitude, 735 feet. Population (1881), 7362; (1901), 8130.

**Ealing,** a suburb of London, England, in the Ealing parliamentary division of Middlesex, 9 miles west of St Paul's, with two railway stations. There are seven Established churches (in St Mary's, 1770, are buried Oldmixon, the historian, and Horne Tooke). Other buildings are public offices, with library and science and art schools, a high school for girls, a training college for teachers of the deaf, an isolation hospital, and a cottage hospital and dispensary. There is a common and a public park. Among former distinguished residents of Ealing were Henry Fielding, the novelist, and John, first duke of Marlborough. Area of urban district, 2928 acres. Population (1881), 15,769; (1891), 23,979; (1901), 33,040.

**Ear.** See PATHOLOGY and PHYSIOLOGY (*special senses*).

**Early, Jubal Anderson** (1816–1894), American soldier and lawyer, was born in Franklin county, Va., on 3rd November 1816, and graduated at the U.S. military academy in 1837. After a brief service he resigned in July 1838, to practise law in Virginia, but as major in a regiment of state volunteers took part in the Mexican War. In 1861 he entered the Confederate service as a colonel, fought at Bull Run (July 1861), received a wound at Williamsburg (May

1862), and was advanced to brigadier- and major-general. His division held the lines at Fredericksburg during the battle of Chancellorsville (May 1863), and he fought in July at Gettysburg. As lieutenant-general in 1864, Early crossed the Potomac in July, and part of his force advanced as far north as Chambersburg, Pa. He threatened Washington with his main force, but was compelled to retreat upon the arrival of the 6th corps, despatched by Grant from the front. In the ensuing autumn he won a partial success in the Shenandoah valley, but General Sheridan checked him in September at Opequan and Fisher's Hill, and on 19th October he suffered a decisive defeat at Cedar Creek. Wholly routed in March 1865, Early was relieved of command, and took no further active part in the war. After the peace he visited Europe, and later resumed the practice of law, managing for a time with Beauregard the Louisiana lottery. He died at Lynchburg, Va., on 2nd March 1894.

**Earth, Figure of the.**—To complete, to link together into one great network of triangles, the geodetic surveys accomplished in various countries, notably in France, England, Russia, and India, is the actual endeavour of astronomers, in order to reach an exact knowledge of the shape and size of the earth. From this common desideratum the International Geodetic Association was born, which has promoted researches directly or indirectly relating to Geodesy. Planned as early as 1861, the I. G. Association grew slowly, and was definitely constituted by the Conventions of 1886 and 1895. The Association meets at least every third year, with the Central Bureau in Potsdam, and its president is Professor Helmert, Director of the Royal Geodetic Institute, founded in 1868, the resources of which are at the disposal of the Association.

The general meeting of the I. G. Association at Paris in September 1900 gave the delegates an opportunity of knowing the state of the surveys in progress and projected.[1] Among these undertakings may first be quoted the measurement of an arc of 66 degrees of amplitude which crosses Africa from the Delta of the Nile to Cape Town; then the measuring of an arc in Spitzbergen, and the remeasurement of the arc of Peru.

The African arc will be surveyed along the meridian of 30° E. Sir David Gill, director of the Cape Observatory, has already given a report of the operations undertaken in South Africa, which will form a good basis for the realization of his admirable project. The Geodetic Survey of South Africa has established an important chain of triangles between the 20th and 30th meridians; it will not be long before this reaches from Cape Agulhas to the Zambezi, embracing thus more than 20° of latitude. Major Laffan and Lieutenant Wettstein, English and German commissioners, have recently measured, under the direction of Sir D. Gill, a chain of triangles along the 20th meridian, which divides Bechuanaland from German South-West Africa, between Rietfontein and the parallel of 22° south latitude. Mr Alston has united, by a chain along the 28th parallel, through Bechuanaland, those already established along the 20th and 24th meridians. The Chartered Company had a triangulation along the 30th meridian undertaken in Rhodesia, and the Geodetic Survey of Rhodesia achieved, amid great difficulties, the observations between Mangwe and the parallel of –19°, and reconnoitred the northern part of the chain up to the Zambezi, when the war in South Africa caused the interruption of these works. As soon as circumstances permit, the chain of Rhodesia will pass through the Transvaal and be linked with that which the Geodetic Survey of South Africa has already measured in Cape Colony and Natal, along the south-eastern shore of Africa, from Cape Agulhas to Vaal river. It is therefore to be expected that the triangulation will before long extend from the Cape to the Zambezi. From this river to the Bahr-el-Gazal, the 30th meridian passes through the territories of the Congo Free State, of German East Africa, and of British East Africa, which it reaches near Albert Edward Nyanza, crossing Lake Tanganyika, which is surrounded by hills visible from one shore to the other, this being a favourable circumstance to facilitate the work. The northern extremity of the African arc is in Egypt, and a triangulation performed along the Mediterranean shore would afterwards avail to link the African arc to the Rumanian and to the Russian arc, so as to form a continuous chain, ranging over 105° from Cape Agulhas to North Cape.

The question of the measurement of an arc in Spitzbergen had already been raised by General Sabine. After the exploration of that archipelago by Nordenskjöld and some others, it was resumed by Professor Rosén, who prepared a scheme of triangulation, and the solution of the problem was deemed possible, on account of the improvements of the base-apparatus of Jäderin, whose nickel-steel wire makes the measuring of an extended base-line much easier than by previous processes.

During the summer of 1898 a private Swedish expedition, conducted by Jäderin, began the reconnaissance of a meridian chain between the parallels of South Cape and Ross Island, thus embracing about 4° 5′ of latitude, between 76° and 81°. The summits of the triangles were to be marked by signals on the shores of the Storfjord, of the Strait of Hinlopen, and of the Seven Isles; the expedition succeeded in placing the signals from Ross Island to the Storfjord. The continuation of the work was then entrusted to two official commissions named by the Swedish and Russian Governments, who proceeded to compose two missions. Towards the end of June 1899 the Russo-Swedish expedition, on five steamships, went from Tromsö to Spitzbergen. The work was postponed till July, because of the ice and the time lost in erecting the cabins, and was then pursued till September. The Russian mission took charge of the installation of the signals in the Storfjord. This was a very heavy task, on account of the elevation of the mountains around the gulf, and of its width, the two shores being seldom at the same moment free from fogs; the consequence being that the sides of many triangles exceed 100 kilometres in length. It was also possible to do some astronomical and geodetical work for two of the most difficult summits, namely, those of Cape Lee and of Whole Point, where a base-line has to be measured. At the north the condition of ice did not permit reaching the Seven Isles; the Swedish mission has been employed in measuring a base-line at Hekla Hook and determining some summits. In September both missions settled in winter stations; the Russians at Hornsund, on the south-western coast of Spitzbergen, in 77° N., the Swedish in the Treurenberg Bay, towards 80°. They remained there, isolated from the outer world, during nine months, occupied in astronomical and meteorological observations. When the spring of 1900 came, the geodetical work was resumed and pursued till September, amidst very unfavourable circumstances. They succeeded with much ado in building up on Mount Chydenius (alt. 1500 metres) a signal destined to join the chain of the Storfjord to that of Hinlopen Strait.

The revision of the arc of Peru, the opportunity for which had already been pointed to by Mr Davidson, the delegate of the United States to the I. G. Association in 1889, and later by Mr Preston in 1898, has been undertaken,

[1] See the valuable reports of Lieut. Perrier and Professor Helmert.

the French Government having been authorized by the Chambers to appropriate to that work a sum of 500,000 francs. The operation was entrusted to the members of the Geographical Service of the Army, under the direction of General Bassot. The Government of the Republic of Ecuador (on whose territory the arc of Bouguer is now comprised) having shown a disposition to favour the enterprise, two French officers, Captains Maurain and Lacombe, of the Geographical Service, were sent in 1899 to reconnoitre the country. They left Bordeaux at the end of May, and returned in January 1900, after having surveyed, in less than five months (July to November), an arc of 6°, between the Cerro de Pasto (1° 10′ N. lat., Colombian territory) and the Cerro Ereo (4° 55′ S. lat., Peruvian territory), thus lengthening by 1° towards the north and 2° southwardly the arc of Bouguer. In the southern part of the arc they could retain the old stations of the French academicians; in the northern part they had to rise above the former stations, found defective. The obstacles were formidable, for there the twin Cordilleras rise to peaks—some of them volcanoes—of from 5000 to 6000 metres in altitude, namely, Pichincha, Chimborazo, Cotopaxi, &c. MM. Maurain and Lacombe, with a zeal and persistence above all praise, traversed 3500 kilometres and effected about thirty ascents in one of the most difficult countries, investigated the sites of two new base-lines, and determined fifteen geodetical stations; they brought back topographical sketches and plans which give a clear idea of the work to be accomplished. In July 1900 an official report, presented by M. Poincaré in the name of the Academy of Sciences, drew out the lines of the projected revision of the arc of Quito. The system implies a series of 57 triangles and is supported by three base-lines, each of about 8500 metres. The principal base will be situated towards the middle of the arc, near Riobamba, in 1° 30′ S. lat., and 2500 metres above the sea-level; two bases of verification are to be established at both extremities: the one near Cumbal, in Colombia, the other between Quiroz and Sullana (Peru). For measuring the angles, 52 stations (28 from the old chain of Bouguer and La Condamine) will be established along both Cordilleras, their altitude being often of 4000 metres; the sides of the triangles will be of 30 to 40 kilometres. The mission will be divided into two parties, who will proceed in parallel lines, the one along the western range, the other along the eastern. As it would be hazardous to build up signals, always liable to be destroyed by the Indians, optic telegraphy will be resorted to, by means of heliostats, in order to maintain communication between the successive stations.

The difference of longitude of the extremities will be a little less than 3°. In the southern part of the Gulf of Guayaquil the hills are near enough to the coast to make it possible to push on the triangulation to the sea, by connecting it with a point where an old lighthouse stands, and also, perhaps, with a point of Puna Island. The altitude of the principal base (Riobamba) will be obtained by a spirit-levelling, which will follow the line of the future Guayaquil Quito railroad. The sea-level will be obtained by means of a "médimarémètre" placed at Playas, on the Pacific coast, distant about 70 kilometres from Guayaquil. The line of levelling from Playas to Riobamba will attain a development of 280 kilometres and rise to 2500 metres. For the other bases a geodetic levelling by zenith distances may suffice. The astronomical stations for the observation of the fundamental elements (latitude, longitude, azimuth) will be multiplied as much as possible, and likewise the stations for pendulum observations. The principal station will be at Quito, where a perfectly fitted observatory already stands, the direction of which has been entrusted to a French astronomer, M. Gonnessiat. The differences of longitude between Quito, Guayaquil, and several other astronomical stations will be determined with the help of the telegraph.

It is estimated that this programme can be executed within four years by a party of five officers, namely, Commandant Bourgeois, head of the mission, Captains Lacombe, Maurain, Lallemand, and Lieutenant Perrier; the other members are a military physician, a mechanician, and sixteen corporals and privates. A vanguard mission, consisting of Captains Maurain and Lallemand, sailed in December 1900, and reached Guayaquil in January 1901. The rest of the personnel followed in April with the instruments.

It is right to recall here that geodetical studies have recovered, in France, their former expansion under the vigorous impulse of Colonel (afterwards General) Perrier. When occupied with the triangulation of Algeria, Colonel Perrier had conceived the possibility of the geodetic junction of Algeria to Spain, over the Mediterranean; therefore the French meridian line, which was already connected with England, and was thus produced to the 60th parallel, could further be linked to the Spanish triangulation, cross thence into Algeria and extend to the Sahara, so as to form an arc of about 30° in length. But it became, then, urgent to proceed to a new measurement of the French arc, between Dunkirk and Perpignan. In 1869 Perrier was authorized by Maréchal Niel to undertake that revision. He devoted himself to that work till the end of his career, closed by premature death in February 1888, at the very moment when the Dépôt de la Guerre had just been transformed into the Geographical Service of the Army, of which General Perrier was the first director. His work was continued by his assistant, Colonel (afterwards General) Bassot. The operations concerning the revision of the French arc (triangulation, remeasurement of the Perpignan base, measurement of a new base near Melun, which may replace the former, &c.) were completed only in 1896. Meanwhile the French geodesists had accomplished the junction of Algeria to Spain, with the help of the geodesists of the Madrid Institute under General Ibañez (1879), and measured the meridian line between Algiers and El Aghouat (1881). They have since been busy in prolonging the meridians of El Aghouat and Biskra, so as to converge towards Wargla, through Gardaïa and Tuggurt. A careful study of the deflections of the vertical has been commenced in the hills of the Algerian Sahel. In France the Geographical Service of the Army has been entrusted with the triangulations of the first, second, and third orders, to serve as a basis for the new map of France.[1] The Geographical Service has thus been led to undertake the revision of the whole triangulation of France, with methods and instruments of high precision. The parallel of Paris has been connected with the German net by the co-operation of German and French geodesists. The fundamental co-ordinates of the Panthéon have also been obtained anew, by connecting the Panthéon and the Paris Observatory with the five stations of Bry-sur-Marne, Morlu, Mont Valérien, Chatillon, and Montsouris, where the observations of latitude and azimuth have been effected.

The triangulation of Italy is finished and in connexion with the French net on north and south, where it is linked to Tunis. The geodetic junction of Malta to Sicily was executed in 1900 by M. Guarducci. The observations were made by night, by means of light signals. The distances of many of the stations reach to 200 kilometres. The probable error in closing the triangles does not exceed

[1] See the work entitled *La Carte de France*, 1750-1898; *Étude historique*, par le Colonel Berthaut, 2 vols. 4to, 1898-99.

two seconds. The connexion of Corsica with the continent by new measures is also contemplated.

Rumania, which since 1895 has had a Geographical Institute of the Army, has not remained backward.[1] Three base-lines have been measured with Brunner's apparatus: the western base, at Garla Mare (6200 metres); the central base, in Bucarest (9420 metres); and the northern base, at Roman (7400 metres). The astronomical observations have been commenced for the measurement of an arc of parallel, supported by three bases (the western, central, and an eastern one, at Slobozia), which will produce to the Black Sea the mean parallel, already measured from the Atlantic. On the other hand, the meridian arc, depending upon three bases (eastern, northern, and a Russian base near the Dniester), will help to join the Russian arc of Struve with the African arc of Gill, in long. 30° E. For their levellings the Rumanian geodesists have adopted the methods employed in the *Nivellement général de la France*, under the direction of M. Lallemand. It has already been reported that there does not exist any difference of mean level between the Black Sea and the Adriatic, contrary to what has hitherto been generally believed.

Greece, also, is now in possession of a valuable survey, which has been effected under Colonel Hartl.

In Russia the Topographical Section of the General Staff has begun great calculations, for the sake of unification of the various triangulations, executed at very different epochs. As spheroid of reference, the Besselian ellipsoid was made use of, which seems to suit better with the surface of the Russian Empire than that of Clarke, which had been utilized several times since 1880. In fact, General Bonsdorff, by a new calculation of the arc of Struve (long. 30° E.), found the ellipticity 1/298·6, scarcely different from Bessel (1/299). On the other hand, Professor Shdanov, by the arcs of the parallels of 52° and 47°, combined with three meridian arcs which run across, found nearly the same result (1/299·7). The Clarke ellipsoid has, on the contrary, a much stronger ellipticity (1/293·5), which results from the influence of the Indian arc.[2]

In the new mathematical treatment of the Russian triangulations, only the geometrical conditions of the system and the astronomical azimuths have been taken into account, leaving aside astronomical longitudes and latitudes, too much influenced by local attractions. It was therefore decided to compute the geodetical co-ordinates of the stations, starting from Dorpat (Yurief) as a point of reference. Besides the three fundamental chains (meridian arc of Struve, arcs of the parallels of 47° and 52°), four polygonal systems were at hand, formed by these chains, and meridian or parallel arcs, measured in the zone comprised between Warsaw and Saratof. The vastness of these systems prevented the application of a uniform method of simultaneous adjustment, and made it necessary to resort to partial adjustments before the final connexion of the several parts of the network.

The results of the computations relative to the parallel of Central Europe (lat. 52°), that ranges over 69° of longitude, with a linear development of 4730 kilometres, from Valentia (Ireland) to the Ural, are now known. The radius of curvature of this parallel is smaller than that corresponding to the Clarke ellipsoid; it belongs to another ellipsoid; according to Helmert, this might be an ellipsoid with the equatorial radius found by Clarke (which is confirmed by the computation of the meridian arc of Struve), but with a much smaller ellipticity, smaller even than Bessel's, *i.e.*, 1/308. It is true that the parallel of 52° presents a very sensible irregularity: the eastern, or Russian, half would agree well enough with Clarke's ellipsoid, but the western half concords better with Bessel's, its average curvature being greater than that of the eastern half. There lies a strong indication of the attraction of continents; this seems to be confirmed by the curvature of the Anglo-French meridian arc, which proves a little greater than that of the Russian arc of Struve, and by the fact that the polar semi-axes of the ellipses of these two arcs do not coincide; they separate by 4″·5, in such a manner that Russian latitudes are too large by 4″·5, or the others too small by the same amount.

The United States Coast and Geodetic Survey has published an account of the transcontinental triangulation and measurement of an arc of the parallel of 39°, which extends from Cape May (New Jersey), on the Atlantic coast, to Point Arena (California), on the Pacific coast, and embraces 48° 46′ of longitude, with a linear development of about 4225 kilometres (2625 st. miles). The triangulation depends upon ten base-lines, with an aggregate length of 86 kilometres, the longest exceeding 17 kilometres in length, which have been measured with the utmost care. "A characteristic of the triangulation is its rigidity, imparted to it by quadrilaterals and other polygons. In crossing the Rocky Mountains, many of its sides exceed one hundred miles in length, and there is one side reaching to a length of 294 kilometres, or 183 st. miles; the altitude of many of the stations is also considerable, reaching to 4300 metres, or 14,108 feet, in the case of Pike's Peak, and to 14,421 feet at Mount Elbert. All geometrical conditions subsisting in the triangulation are satisfied by adjustment, inclusive of the required accord of the base-lines, so that the same length for any given line is found, no matter from what line one may start."[3]

Over or near the arc were distributed 109 latitude stations, occupied with zenith telescopes; 73 azimuth stations; and 29 telegraphically determined longitudes. It has thus been possible to study in a very complete manner the deviations of the vertical, which in the mountainous regions sometimes amount to 25 seconds, and even to 29 seconds. According to Mr Schott, the average curvature of the surface of the geoid, along the parallel of 39°, approaches closely to that of the Clarke spheroid in the eastern part of the arc, which extends from the Atlantic to the Rocky Mountains, and to that of the Besselian spheroid in the western part, on the Pacific side, which represents $\frac{3}{7}$ of the arc. Thus in North America as well as in Europe the curvature increases from east to west. Some preliminary combinations of this arc with other American arcs lead to spheroids approaching that of Clarke.

The computations relative to another arc, the "eastern oblique arc of the United States," are also available. It extends from Calais (Maine) in the north-east, to the Gulf of Mexico, and terminates at New Orleans (Louisiana), in the south. Its length is 2612 kilometres (1623 st. miles), the difference of latitude 15° 1′, and of longitude 22° 47′. In the main, the triangulation follows the Appalachian chain of mountains, bifurcating once, so as to leave an oval space between the two branches. It includes among its stations Mount Washington (1920 metres) and Mount Mitchell (2038 metres). It depends upon six base-lines, and the adjustment is effected in the same manner as for the arc of the parallel. The astronomical data have been afforded by 71 latitude stations, 17 longitude stations, and 56 azimuth stations, distributed over the whole extent of the arc. For various reasons a selection had, however,

to be made among these data, a part of which only was admitted into the final equations for the determination of the best spheroid (84 data out of 144). The resulting dimensions of an osculating spheroid were found to be

| | |
|---|---|
| Equatorial radius . | . 6,378,157 ± 90 metres. |
| Compression (ellipticity) . | 1/304·5 ± 1·9. |

The equatorial radius differs but little from Clarke's value of 1866, whereas the compression is very different, and comes more nearly to Bessel's value.

The measurement of a great meridian arc, in long. 98° W., has also begun; it has a range of latitude of 23°, and will extend over 50° when produced southwards and northwards by Mexico and Canada. It may afterwards be connected with the new arc of Quito. Geodetical surveys of some extent have also been undertaken in New South Wales and in Queensland.

Differences of longitude were measured along the circuit Greenwich–Pulkowa–Vladivostok–Shanghai–Madras–Tehran–Potsdam–Greenwich.

We transcribe from Mr Schott a comparative table of the dimensions of several spheroids which of late have been often quoted:—

| Ellipsoid of | Equatorial Radius $a$. | Polar Semi-Axis $b$. | Compression $(a-b)/a$. |
|---|---|---|---|
| | m. | m. | |
| Bessel, 1841. From ten meridional arcs, total amplitude 90°·6 . . . . | 6,377,397 | 6,356,079 | 1/299·15 |
| Clarke, 1858. Special spheroid for surface of Great Britain and Ireland; range of lat. 12°, the same in long.; 75 astron. stations | 6,378,494 | 6,355,746 | 1/280·4 |
| Clarke, 1866. From five merid. arcs, total amplitude 76°·6 . . . . | 6,378,206 | 6,356,584 | 1/295·0 |
| Clarke, 1880. From five merid. arcs and longitudinal measures, total amplitude 89°·0 . . . | 6,378,249 | 6,356,515 | 1/293·5 |
| U.S. Coast and Geod. Survey, 1900. Eastern oblique arc; total length 23°·5; 84 astronomic stations . . | 6,378,157 | 6,357,210 | 1/304·5 |
| Bonsdorff, 1899. Russian merid. arc, amplitude 25°·3 | 6,378,344 | 6,356,983 | 1/298·6 |
| Shdanov, 1899. Russian parallels of 47° and 52°, and three merid. arcs . | 6,377,717 | 6,356,437 | 1/299·7 |
| Harkness, 1891. From a variety of sources (*Solar Parallax*, Washington, 1891) . . . . | 6,377,972 | 6,356,727 | 1/300·2 |

It is thus evident that great efforts are now being made by all civilized nations to complete the network of triangles that will ere long cover the whole surface of the continents. In due course we shall be in possession of the results of some of the most important undertakings, now in process of execution. Meantime it may be admitted as highly probable that the dimensions of the geoid are nearly those adopted by Clarke ($a > 6,378,000$ metres), with an ellipticity approaching to Bessel's value (1/299). The ellipsoid of three unequal axes has been abandoned, mainly for theoretical reasons [1] that lead us to prefer an ellipsoid of revolution as a reference spheroid, in relation to which may be stated the prominences and depressions of the true geoid. In Europe, according to Helmert, the deviations of level are scarcely over 100 metres.

But it is necessary to agree precisely on the definition of the geoid. This word is generally understood to mean a level surface coinciding with the mathematical surface of the sea, produced below the continents, which it is imagined to percolate by canals or open cuttings. In that case the reduction of gravity to the sea-level ought to be done simply by the correction for height $\left(+2g\frac{h}{R}\right)$, just as if the superposed strata were condensed upon the surface of the geoid. A somewhat different geoid would be obtained by supposing the surface of the oceans continued below the continents by means of tunnels, or by a levelling in mine galleries, for then the attraction of the upper strata diminishes the gravity at the surface of the geoid, and the latter will be a little below the surface of the former geoid; it has discontinuities of curvature where it enters the continents. If now, according to what is often done, we add to the reduction of gravity Bouguer's correction $\left(-\frac{3}{2}g\frac{\delta}{\Delta}\frac{h}{R}\right)$, which goes to subtract the attraction of the continent, $\delta$ being the density of the ground, and $\Delta$ the mean density of the earth, we thereby suppose the upper layers erased; but the process is inadmissible, since we know that mountain masses are generally compensated by a deficiency of matter in the underlying strata. In Europe the compensation is often found to be incomplete, whereas in the Himalaya range the attracting masses are sometimes over-compensated.

Professor Helmert, who has devoted much labour and time to the calculations of measures of gravity by means of pendulum observations, has proposed another mode of reduction, which is known by the name of "condensation method." He imagines the upper strata condensed upon the surface of a geoid situated at a depth of 21 kilometres (its equatorial radius being, therefore, equal to the polar semi-axis of the earth). This process, conceived with a view to facilitate the development of the potential, presents the inconvenience of introducing many very uncertain data, and may seem somewhat artificial. Professor Helmert has found that it brings into fair agreement the numerous measures of gravity already obtained. The number of stations is about 1400, out of which more than 50 have been connected with the central bureau in Potsdam. A thorough examination of the deflections of the vertical, or local attractions, observed in all parts of Europe has also been undertaken by the central bureau.

According to Helmert, the ellipticity of the earth, as derived from pendulum observations, is 1/299·3 (in his latest paper the corrected result is 1/298·3), and from the lunar theory 1/297·8; Hansen's value is 1/296·2. Lastly, M. Radau has shown [2] that by the introduction of the variable $\eta = \frac{c\,de}{e\,dc}$, where $c, e$ are the mean radius and ellipticity of a spheroid, it becomes possible to integrate approximately the equations of Clairaut, and to establish a relation which affords the means for an independent evaluation of the ellipticity of the earth. The subject is very fully gone into in two important memoirs, one by M. Callandreau,[3] the other by Professor Darwin,[4] whose results point to an ellipticity between 1/296 and 1/298. Professor Darwin further concludes that the level surface of the earth is depressed below the true ellipsoid by 3 metres in latitude 45°. It is highly probable that a value

differing but little from Bessel's (1/299) will be finally adopted. It must, of course, be borne in mind that the spheroid here considered is a spheroid of reference, and that the true geoid may present many irregularities.

A question which has much absorbed the attention of geodesists of late years, but which need only be briefly mentioned here, is that of the *variation of latitudes*, resulting from a periodical shift of the axis of rotation on the surface of the earth. Suspected by Bessel (1817), the variability of latitudes was proved by the researches of Peters (1844) and Nyrén (1873), founded on the observations of Pulkowa; but these astronomers had found only a very slight amplitude ($0''\cdot10$) in adopting the ten-months' period, which seemed pointed to by Euler's theory. The researches of Clerk Maxwell (1857), Fergola (1872), Downing (1880), Küstner (1888), having once more attracted attention to this subject, in the year 1889 the observatories of Berlin, Potsdam, Prague, and Strasburg concerted a plan for regular determinations of latitude by Talcott's method; and variations of from $0''\cdot3$ to $0''\cdot5$ were brought to light. Since then many other observatories have taken part in the work, and a special expedition was sent to Honolulu in 1891. Professor Albrecht every year brings together the results of the gathered observations. From his detailed reports it follows that, since 1890, the pole of rotation of the earth has described an irregular spiral, of variable amplitude, around a mean position from which it does not deviate by more than $0''\cdot3$. On the other hand, Mr S. C. Chandler, by a careful discussion of observations from 1825 to 1893, arrived at the conclusion that the latitude variation is composed of two terms, one having a period of 14 months (429 days), the other a mean period of a year, with amplitudes varying from $0''\cdot10$ to $0''\cdot20$; he thinks the annual component may be elliptical. As to the theoretical question of the causes of these variations, Lord Kelvin has already stated that meteorological influences might be the cause of annual variations so great as $0''\cdot5$. M. Radau has further shown[1] that the combination of an annual period with another period, such as the Eulerian one, could result in great amplification of the effects. Finally, Professor Newcomb has explained the existence of the fourteen-months' period by the influence of the elasticity of the earth. It was for the sake of an exhaustive study of these questions that an "International Service of Latitudes" was organized in 1899 by the Geodetic Association in six observatories distributed along the parallel of 39°. (R. RA.)

**Earthquakes.**—Strange as it may appear, the advances that have been made in the study of earthquakes, and the world-wide interest shown in their phenomena, were initiated in work commenced in Japan. When the Japanese Government, desiring to adopt Western knowledge, invited to its shores bodies of men to act as its instructors, the attention of the newcomers was naturally attracted to the frequent shakings of the ground. Interest in these phenomena increased more rapidly than their frequency, and at length it was felt that something should be done for their systematic study. At midnight on 22nd February 1880 movements more violent than usual occurred; chimneys were shattered or rotated, tiles slid down from roofs, and in the morning it was seen that Yokohama had the appearance of a city that had suffered a bombardment. The excitement was intense, and before the ruins had been removed a meeting was convened and the Seismological Society of Japan established. The twenty volumes of original papers published by this body summarize to a large extent the results of the later study of Seismology.

***Attention now given to seismology.***

The attention of the students of earthquakes in Japan was at first directed almost entirely to seismometry or earthquake measurement. Forms of apparatus which then existed, as for example the seismographs, seismometers, and seismoscopes of Mallet, Palmieri, and others, were subjected to trial; but inasmuch as they did little more than indicate that an earthquake had taken place—the more elaborate forms recording also the time of its occurrence—they were rapidly discarded, and instruments were constructed to *measure* earthquake motion. To describe the varieties of apparatus devised in Japan and their purposes would require a special volume on Seismometry. Slightly modified types of the new instruments were adopted throughout the Italian peninsula, and it is fair to say that the seismometry developed in Japan revolutionized the seismometry of the world. The records obtained from the new instruments increased our knowledge of the character of earthquake motion, and the engineer and the architect were placed in a position to construct so that the effects of known movements could be minimized. It was no doubt the marked success, both practical and scientific, attending these investigations that led the Japanese Government to establish a chair of Seismology at its University, to organize a system of nearly 1000 observing stations throughout the country, and in 1893 to appoint a committee of scientific and practical men to carry out investigations which may palliate the effects of seismic disturbances. In the first year this committee received a grant of £5000, and as liberal sums for the same purpose appear from time to time in the parliamentary estimates, it may be assumed that the work has been fraught with good results. In their publications we find records not only of experiences and experiments in Japan, but descriptions and comments upon earthquake effects in other countries. In two of the volumes there are long and extremely well-illustrated accounts of the earthquake which on 12th June 1897 devastated Assam, to which country two members of the above-mentioned committee were despatched to gather such information as might be of value to the architect and builder in earthquake-shaken districts.

***Seismological research.***

A great impetus to seismological investigation in Europe and America was no doubt given by the realization of the fact that a large earthquake originating in any one part of the world may be recorded in almost any other. Italy for many years past has had its observatories for recording earthquakes which can be felt, and which are of local origin, but at the present time at all its fifteen first-class stations we find instruments to record the unfelt movements due to earthquakes originating at great distances, and as much attention is now paid to the large earthquakes of the world as to the smaller ones originating within Italian territory. The Kaiserliche Akademie der Wissenschaften of Vienna has established earthquake observatories in Austria, and the Central Observatorium of St Petersburg has carried out similar work in Russia. Germany, at a cost of £3500 and with an annual allowance of £295, has attached a seismological observatory to its university at Strassburg, whilst provision has been made for a professorship of Earth Physics at Göttingen. In accordance with the recommendation of the British Association of Great Britain, seismographs of a similar character have been installed at the following places:—Isle of Wight, Kew, Paisley, Toronto, Victoria (B.C.), Philadelphia, Mexico, Trinidad, Arequipa, Cordova in Argentina, New Zealand, Hawaii, Japan, Java, Calcutta, Madras, Bombay Mauritius,

[1] *Comptes Rendus*, t. cxi., 1890.

the Cape of Good Hope, Cairo, Beyrout, San Fernando in Spain. The principal objects of this extended and still extending system of stations are to determine the velocity with which motion is propagated over the surface and through the interior of the earth, to locate the positions of sub-oceanic earthquake origins, and generally to extend our knowledge respecting the physical nature of the planet on which we live.

We now know that earthquakes are many times more frequent than was previously supposed. In Japan, for example, between 1885 and 1892 no fewer than 8331 were recorded—that is to say, on the average there were during that time more than 1000 disturbances per year. Although many of these did not cause a sensible shaking over areas exceeding a few hundred square miles, many of them were sufficiently intense to propagate vibrations round and through the globe. If we pick out the well-marked earthquake districts of the world, and give to each of them a seismicity or earthquake frequency per unit area one-third of that in Japan, the conclusion arrived at is that considerable areas of our planet are on the average shaken every half-hour.

***Frequency of earthquakes.***

The knowledge which we now possess respecting the localities where earthquakes are frequent and the forms of the foci from which they have spread, enables us to speak definitely respecting the originating causes of many of these phenomena. It is found, for example, that although in many countries there may be displays of volcanic and seismic activity taking place almost side by side, it is only rarely that there is direct relationship between the two. Now and then, however, before a volcano breaks into eruption there may be a few ineffectual efforts to form a vent, each of which is accompanied by no more than a slight local shaking of the ground. This is true even for the largest and most violent eruptions, when mountains have with practically a single effort blown off their heads and shoulders. Thus the earthquake which accompanied the eruption of Bandaisan, in Central Japan, in 1888 was felt only over a radius of 25 miles. The analyses of the seismic registers of Japan clearly indicate that comparatively few shakings originate near to the volcanoes of the country, the majority of them, like those of many other countries, coming from regions where volcanic rocks are absent. The greatest number spread inland from the Pacific sea-board, the movement becoming more and more feeble as it approaches the backbone of the country, which is drilled with numerous volcanic vents. What is true for Japan is generally true for the western coasts of North and South America.

***Volcanoes and earthquakes.***

Speaking broadly, earthquakes are most frequent along the steeper flexures in the earth's surface, and in those regions where there is geological evidence to show that slow secular movements in the earth's crust are possibly yet in progress. With a unit distance of 2 degrees, or 120 geographical miles, we find that the slopes running eastwards from the highlands of Japan and westwards from the Andean ridges down into the Pacific vary from 1 in 20 to 1 in 30, and it is on the faces or near to the bottom of these slopes that seismic efforts are frequent. The slopes running from Australia, Eastern America, and Western Europe into the neighbouring oceans vary between 1 in 70 and 1 in 250, and in these regions earthquakes are of rare occurrence. The seismic activity met with in the Himalayas and the Alps finds its best explanation in the fact that these mountains are geologically recent, and there are no reasons to doubt that the forces which brought their folds into existence are yet in action.

***Origin of earthquakes.***

This peculiar association of earthquakes with pronounced topographical configuration and certain geological conditions evidently indicates that the origin of many of them is connected with rock folding. Inasmuch as certain large earthquakes have been accompanied by rock fracture, as for example in 1891, when in Central Japan a fault some 50 miles in length was created, whilst the origins of others have been distinctly traced to the line of an existing fault or its continuation, we may conclude that the majority of earthquakes are spasmodic accelerations in the secular movements which are creating (and in some instances possibly obliterating) the more prominent features of the earth's surface. These secular movements, which include upheavals, subsidences, horizontal displacements, all of which are explained on the assumption of a crust seeking support on a nucleus gradually contracting by loss of heat, are collectively referred to as bradyseismical ($\beta\rho\alpha\delta\acute{\upsilon}\varsigma$ = slow) movements. To these may be added movements directly attributable to the influence of gravity. Sub-oceanic districts in a state of seismic strain may be so far loaded by the accumulation of sediments that gentle bending may be accompanied by sudden yieldings. This possibly accounts for the frequency of earthquakes off the mouth of the Tonegawa on the eastern side of Japan. The distortions so frequently observed in fossils and pebbles, the varying thickness of contorted strata, and the "creep" in coal mines, together with other phenomena, indicate that rocks may flow. Observations of this nature lead to the supposition that high plateau-like regions may be gradually subsiding under the influence of their own weight, and that the process of settlement may from time to time be spasmodic in its character. Whether the earthquakes which originate round the submerged basal frontiers of the continents bounding the Pacific are ever attributable to such activities, it is impossible to say. All that we know with certainty is that they are sometimes accompanied by such a vast displacement of material that the ocean has been set into a state of oscillation for periods of 24 hours, that in some instances there have been marked changes in depth, and that enormous sub-oceanic landslips have occurred. These phenomena are, however, equally well explained on the assumption of sudden faulting accompanied by violent shaking, which would dislodge steeply-inclined beds of material beneath the ocean as it does upon the land.

Although the proximate cause of earthquake motion is traced to sudden yieldings in the crust of the earth brought about by some form of bradyseismical action, the existence of at least two distinct types of seismic motion indicates that the mechanical conditions accompanying the fracturing of rocks are not always identical. Ninety or ninety-five per cent. of the earthquakes which can be recorded consist of elastic or quasi-elastic vibrations. The remainder, including the large earthquakes, not only exhibit the elastic movements, but are accompanied by surface undulations which are propagated most certainly for some hundreds of miles round their origin, and then as horizontal movements sweep over the whole surface of the globe. The former of these may accompany the formation of a new fault or the sudden renewal of movement along an old one; they are cracking or rending effects, without any great displacement. The latter are probably fracturings accompanied by vertical and horizontal displacements of masses of the earth's crust sufficiently great to set up the observed surface undulations. These shocks are so frequently followed a few minutes later by disturbances, which from their similarity to the movements which have preceded them may be called earthquake echoes, that we are led to the speculation that we are here dealing

***Two types of earthquake motion.***

with the caving-in of ill-supported portions of the earth's crust, the waves from which are radiated to boundaries and then returned to their origin to coalesce and give rise to a second impulse not unlike the primary. Succeeding the first repetition of motion recorded by the seismograph there is often a rhythmical repetition of similar wave groups, suggesting the existence within our earth of phenomena akin to multiple echoes.

***Seismometry.*** Before considering in greater detail the nature of earthquake motion, something may be said respecting the instruments by which our knowledge of the subject has been gained. Popularly it is supposed that earthquake recorders are instruments so sensitive to slight vibrations that great care is necessary in selecting a site for their installation. Although this supposition is correct for a certain class of apparatus, as for example that which will record rapid elastic vibrations produced by the movement of a train a mile distant, it is far from being so for the ordinary apparatus employed by the seismologist. What he usually aims at is either to record the more or less rapid movements of the ground which we can feel, or the slow but large disturbances which do not appeal to our unaided senses. Generally speaking, the instruments used for these purposes are not disturbed by the vibrations resulting from ordinary traffic. In almost every household something may be found which will respond to a gentle shaking of the ground. Sometimes it is a loosely-fitting shutter or window-frame, a hanging drawer-handle, or a lamp-shade which will rattle; the timbers in a roof may creak, or a group of wine-glasses with their rims in contact may chatter. Any of these sounds may call attention to movements which otherwise would pass unnoticed. Specially arranged contrivances which tell us that the ground has been shaken are called seismoscopes or earthquake indicators. A small column, as for example a lead pencil standing on end, or a row of pins propped up against suitable supports, or other bodies which are easily overturned, may be used as seismoscopes. Experience, however, has shown that contrivances of this order are wanting in sensibility, and often remain standing during movements that are distinctly perceptible. A more satisfactory arrangement is one where the body to be overturned is placed upon a platform which exaggerates the movements of the ground. For example, the platform $h$ (see Fig. 1) may be on the top of a small rod $r$, fixed at its lower end by plaster of Paris in a watch-glass $w$, and carrying a disc or sphere of lead at $l$. When the stand on which $w$ rests is shaken, a multiplied representation of this movement takes place at $h$, and any small body resting on that point, as for example a small screw $s$ standing on its head, may be caused to topple over. If the loaded rod is elastic its lower end may be fixed in a stand, and the spherically curved base $w$ is no longer required. In this case the motion at $h$ is that of elastic switching. Apparatus of this kind may be employed for several purposes beyond merely indicating that an earthquake has taken place. For example, if the falling body $s$ is attached by a thread to the pendulum of a timepiece, it may be used to stop it and indicate the approximate time at which the tremor occurred. In its most sensitive form $r$ is a steel wire, the upper end of which passes freely through a small hole in a metal plate. By the movement of the wire or the movement of the plate, especially if the latter projects from the top of a second and similar piece of apparatus, an electrical contact can be established by means of which an electromagnet may ring a bell, stop a clock, or set free machinery connected with a cylinder or other surface upon which an earthquake machine may record the movement of the ground.

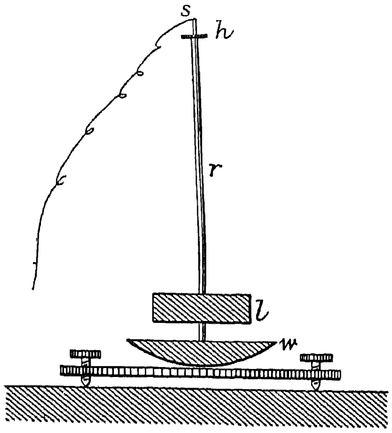

Fig. 1.

The next class of instruments to be considered are seismometers or earthquake measurers, and seismographs, or instruments which give diagrams of earthquake motion. Although a seismograph may be designed that will not only respond to fairly rapid elastic vibrations, but will also record very slow and slight undulatory movements of the ground, experience has shown that the most satisfactory results are obtained when special instruments are employed for special purposes.

First we will consider the types of apparatus which are used to record the rapid back-and-forth movements of earthquakes which can be distinctly felt and at times are even destructive. The essential feature in these seismographs is a fairly heavy mass of metal, so suspended that although its supports are moved, some point in the mass remains practically at rest. For small earthquakes, in which the movement is rapid, the bob of a very long and heavy pendulum will practically comply with these conditions. If a style projecting from this pendulum rests upon say the smoked surface of a glass plate fixed to the ground, the vibratory motion of the ground will be recorded on the glass plate as a set of superimposed vibrations. To obtain an open diagram of these movements the plate must be moved, say by clockwork.

Experience, however, has shown that even when the movements of the ground are alarming the actual range of motion is so small that a satisfactory record can be obtained only by some mechanical (or optical) method of multiplication. This is usually accomplished as shown in Fig. 2. B is the bob of a pendulum, with its style $s$ passing through a slot in the short arm of a light lever, $sop$, pivoted at $o$, and with its outer end resting upon a revolving cylinder covered with smoked paper. As shown in the figure, it is evident that the motion of $o$ in the line $sop$ would not be recorded, and to obtain a complete record of horizontal movements it is necessary to have two levers at right angles to each other. A complete arrangement of this kind is shown in the plan of Fig. 2. Here the style $s$ of the pendulum rests in slots in the short arms of two writing levers pivoted at $o$ and $o'$. Motion of the ground in the direction $os$ actuates only the lever $so'p'$, motion in the direction $o's$ actuates only $sop$, whilst motion in intermediate directions actuates both. The length of the short arms of the levers is usually $\frac{1}{8}$ or $\frac{1}{12}$ of the long arms.

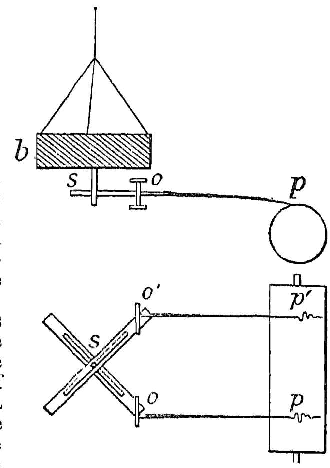

Fig. 2.

Although this type of apparatus is still largely employed in the Italian observatories, it has been replaced in Japan by what are called duplex pendulum seismographs. ***Duplex pendulums.*** The change was made because it frequently happened that in consequence of the movement of the ground agreeing with the period of the pendulum, the latter no longer acted as a steady point, but was caused to swing, and the record became little better than that given by a seismoscope. Very long pendulums (30 to 40 feet) are less subject to this disadvantage, but on the other hand their installation is a matter of some difficulty. A duplex pendulum (Fig. 3) consists of an ordinary pendulum diagrammatically represented by $ab$, connected by a universal joint to an inverted pendulum $dc$. The latter, which is a rod pointed at its lower end and loaded at $c$, would be unstable if it were not connected with $b$. Now imagine this system to be suddenly displaced so that $a$ moves to $a'$ and $d$ moves to $d'$. In the new position $b$ would tend to follow the direction of its point of support, whilst $c$ would tend to fall in the opposite direction, and the bob of one pendulum would exercise a restraint upon the motion of the other. If, as in practice, the moment of $b$ is made slightly greater than that of $c$, the system will come *slowly* to a vertical position beneath $a'd'$. In this way, by coupling together an ordinary pendulum about 3 feet in length with an inverted pendulum 2 ft. 6 in. long, it is easy to obtain the equivalent of a slowly-moving very long pendulum which is too sluggish to follow the back-and-forth movements of its supports.

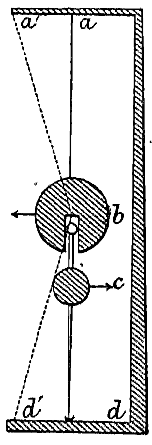

Fig. 3.

To complete an instrument of this description (see Fig. 4) a point in the steady mass $b$ is used as the fulcrum for the short arm of a light-writing index. This has a ball joint at $s$, a universal joint at $o$, and a writing point at $p$, resting upon a piece of smoked glass. Attention was first directed to the possibility of rendering ordinary pendulums more truly astatic by Professor Thomas

Gray, who suggested methods by which this might be accomplished. The method shown in Fig. 4 is that devised by Professor J. A. Ewing. Records obtained from instruments of this description give information respecting the range and principal direction of motion, and show us that in a given earthquake the ground may move in many azimuths.

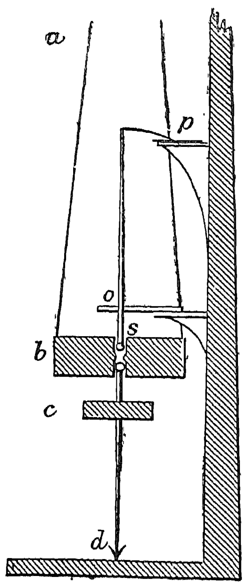

Fig. 4.

For obtaining an open diagram of an earthquake the best type of apparatus consists of a pair of horizontal pendulums writing their movements upon a moving surface. A simple form of horizontal pendulum as shown in Fig. 5, consists of a rod, *op*, free to swing like a gate round a vertical or nearly vertical axis, *cc'*, and loaded at some point *b*. In practice the weight *b* is pivoted on the rod whilst its outer end, *bp*, which writes on a smoked surface, is made extremely light. When the frame of this arrangement is rapidly displaced through a small horizontal range to the right and left of the direction in which the rod points, the weight *b* by its inertia tends to remain at rest, and the motion of the frame, which is that of the earth, is magnified in the ratio *op* to *bp*. This apparatus, of which there are many types, was first introduced into seismometry by Professor Ewing.

***Horizontal pendulums.***

To obtain a complete record of horizontal motion, two of these pendulums are placed at right angles; and by cranking one of the writing levers, *o'p'*, as shown in the plan of Fig. 5, two rectangular components of the earth's movements are written side by side. Since the movements of the ground are frequently accompanied by a slight tilting, which would cause *b* or *b'* to swing or wander away from its normal position, a sufficient stability is given to the weights by inclining the axis of the instrument at *cc'* slightly forwards. Although by compounding corresponding portions of the diagrams given by instruments of this type, it is possible to determine the range and direction of the movement of which they are the resolved parts, their

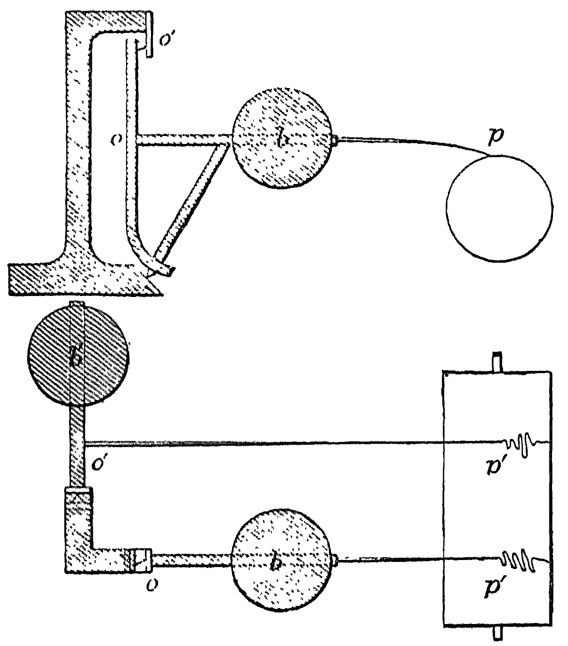

Fig. 5.

chief value is that they enable us to measure with ease the extent of any vibration, half of which is called its amplitude, and the time taken to make any complete back-and-forth movement, or its period. Now if $a$ be the amplitude expressed in millimetres, and $t$ the period expressed in seconds, then the maximum velocity of an earth particle as it vibrates to and fro equals $2\pi a/t$, whilst the maximum acceleration equals $4\pi^2 a/t^2$. The former quantity determines the distance to which a body, as for example the capping of a pillar, may be projected, whilst the latter measures the effort exerted by an earthquake to overturn or shatter various bodies. If after a heavy earthquake we find bodies that have been projected or overturned, then by observing the distance of projection, and the height through which they have fallen, or their dimensions, we can by means of simple formulæ calculate quantities closely agreeing with those obtained from the seismogram. For example, if a body, say a coping-stone, has been thrown horizontally through a distance $a$, and fallen from a height $b$, the maximum horizontal velocity with which it was projected equals $\sqrt{\frac{ga^2}{2b}}$; or if the height of the centre of gravity of a column like a gravestone above the base on which it rests is $y$, and $x$ is the horizontal distance of this centre from the *edge* over which it has turned, then the acceleration or suddenness of motion which caused its overthrow is measured, as pointed out by Mr C. D. West, with fair accuracy by the quantity $g\frac{x}{y}$.

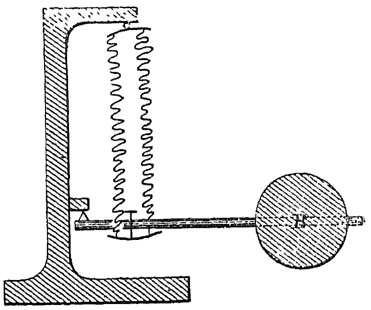

Fig. 6.

To measure vertical motion, which with the greater number of earthquakes is not appreciable, a fairly steady mass to which a multiplying light-writing index can be attached is obtained from a weight carried on a lever held by any form of spring in a horizontal position. Such an arrangement, for which seismologists are indebted to Professor T. Gray, is shown in Fig. 6, in which B is the mass used as the steady point. This, when supported as shown, can be arranged to have an extremely slow period of vertical motion, and in this respect be equivalent to a weight attached to a very long spring, an alternative which is, however, impracticable. The value of these records, as is the case with other forms of seismographs, is impaired by pronounced tiltings of the ground.

***Gray's seismograph.***

We next turn to types of instruments employed to record earthquakes which have radiated from their origins, where they may have been violent, to such distances that their movements are no longer perceptible. In these instruments the same principles are followed as in the construction of horizontal pendulums, the chief difference being that the so-called steady mass is arranged to have a much longer period than that required when recording perceptible earthquakes. Instruments largely employed for this purpose in Italy are ordinary pendulum seismographs as in Fig. 2. The largest of these is one at Catania. It consists of a weight of 300 kilos suspended by a wire 25 metres in length, the movements of which by means of writing indexes are multiplied 12·5 times. With pendulums of shorter length, say 2 metres, it is necessary to have a multiplication 80 to 100 fold by a double system of very light levers, in order to render the extremely slight tilting of their support perceptible. This arrangement, as devised by Professor Vicentini, will yield excellent diagrams of the gentle undulations of earthquakes which have originated at great distances, but for local disturbances, even if the bob of the pendulum acts as a steady point, the displacements are usually too great to be recorded on ordinary record-receiving surfaces when so largely multiplied.

***Instruments to record distant earthquakes.***

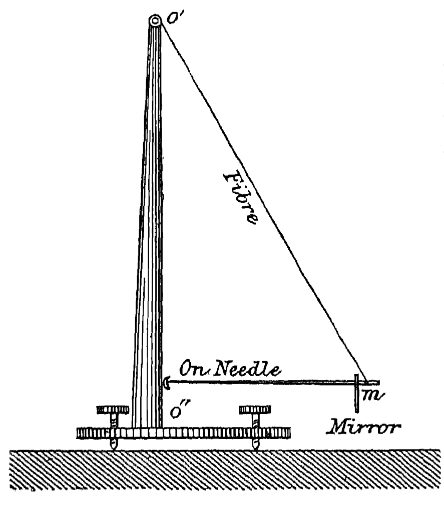

Fig. 7.

In Japan, Germany, Austria, England, and Russia horizontal pendulums of the von Rebeur-Paschwitz type are employed, which by means of levelling screws are usually adjusted to have a natural

period or double swing of from 15 to 30 seconds. These pendulums are usually small. The swinging arm or boom is from 4 to 8 inches long horizontally, and carries at its extremity a weight of a few ounces. A simple form, which is sometimes referred to as a conical pendulum, may be constructed with a large sewing needle carrying a galvanometer mirror, suspended by means of a silk or quartz fibre as shown in Fig. 7. To avoid the possibility of displacements due to magnetic influences, the needle may be replaced by a brass or glass rod. The adjustment of the instrument is effected by means of screws in the bed-plate, by turning which the axis $o'o''$ may be brought into a position nearly vertical. As this position is approached the period of swing becomes greater and greater, and sensibility to slight tilting at right angles to the plane of $o'o''m$ is increased. The movements of the apparatus, which when complete should consist of two similar pendulums in planes at right angles to each other, are recorded by means of a beam of light, which, after reflexion from the mirror or mirrors, passes through a cylindrical lens and is focussed upon a moving surface of photographic paper. The more distant this is from the pendulum the greater is the magnification of the angular movements of the mirror. With a period of 18 seconds, and the record-receiving paper at a distance of about 15 feet, a deflexion of 1 millimetre of the light spot may indicate a tilting of $\frac{1}{100}$ part of a second of arc, or 1 inch in 326 miles. Although this high degree of sensibility, and even a sensibility still higher, may be required in connexion with investigations respecting changes in the vertical, it is not necessary in ordinary seismometry.

A type of instrument which has sufficient sensibility to record the various phases of unfelt earthquake motion, and which, at the suggestion of a committee of the British Association, has been adopted at many observatories throughout the world, is shown in Fig. 8. With an adjustment to give a 15-second period, a deflexion of 1 mm. at the outer end of the boom corresponds to a tilting of the bed-plate of $0''\cdot5$, or 1 inch in 6·4 miles. The record is obtained by the light from a small lamp reflected downwards by a mirror so as to pass through a slit in a small plate attached to the outer end of the boom. The short streak of light thus obtained moves with the movement of the boom over a second slit perpendicular to the first and made in the lid of a box containing clockwork driving a band of bromide paper. With this arrangement of crossed slits a spot of light impinges on the photographic surface and, when the boom is steady, gives a sharp line line. The passage of the long hand of a watch across the end of the slit every hour cuts off the light, and gives hour

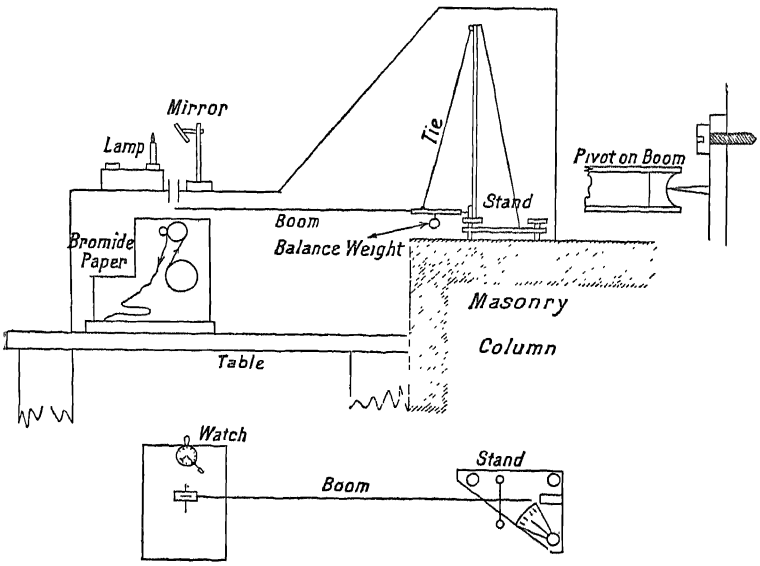

Fig. 8.

marks enabling the observer to learn the time at which a disturbance has taken place. The chief function of the instrument is to measure slow displacements due to distant earthquakes. For local earthquakes it will move relatively to the pivoted balance weight like an ordinary bracket seismograph, and for very rapid motion it gives seismoscopic indications of slight tremors due to the switching of the outer end of the boom, which is necessarily somewhat flexible. If we wish to obtain mechanical registration from a horizontal pendulum of the above type, we may minimize the effect of the friction of the writing index—say a glass fibre touching the smoked surface of moderately smooth paper—by using a considerable weight and placing it near to the outer end of the boom. In the Isle of Wight there is a pair of pendulums arranged as in Fig. 5. The stand is 3 feet in height. Weights of 10 ℔ each are carried at a distance of 10 inches from the pivots of booms which have a total length of 34 inches. With these, or even with booms half the above length, actuating indices arranged as shown in Fig. 2, but multiplying the motion six or seven times, good results may be obtained. At Rocca di Papa near Rome there is a pair of horizontal pendulums with booms 8 feet 9 inches in length, 17 feet in vertical height, which carry near their outer ends weights exceeding half a hundredweight. Although such apparatus is far too cumbersome to be used by ordinary observers, it yields valuable results.

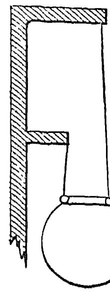

Fig. 9.

An apparatus of great value in measuring slight changes in the vertical which have a bearing upon seismometrical observation is the Darwin bifilar pendulum. This consists of a mirror about half an inch in diameter, which, when it is suspended as shown in Fig. 9, rotates by tilting at right angles to the paper. By this rotation a beam of light reflected from the surface suffers displacement. It is possible to adjust the apparatus so that a tilt of $\frac{1}{1000}$ sec. of arc, or a change of slope of 1 inch in 1000 miles, can be detected.

***Character of earthquake motion.***

The introduction of these new methods into seismometry quickly revolutionized our ideas respecting the character of earthquake motion. Although an earthquake may be strongly felt within a distance of 50 miles from its origin, and although the movements in the upper storeys of buildings within the shaken area may be large, the actual range of the horizontal motion of the ground is usually less than $\frac{1}{10}$ of an inch. With such earthquakes ordinary seismographs for recording vertical motion do not show any disturbance. When the movement reaches $\frac{1}{2}$ inch it becomes dangerous, and a back-and-forth movement of an inch is usually accompanied by destructive effects. In this latter case the amplitude of the vertical record which indicates the existence of surface waves will vary between $\frac{1}{2}$ and $\frac{1}{100}$ of an inch. In the earthquake which devastated Central Japan on 26th October 1891, nearly every building within the epifocal district fell, the ground was fissured, forests slipped down from mountain sides to dam up valleys, whilst the valleys themselves were permanently compressed. The horizontal movements seem to have reached 9 inches or a foot, and the surface undulations were visible to the eye.

***Period and duration.***

The rapidity with which the movements are performed varies throughout a disturbance. A typical earthquake usually commences with minute elastic vibrations, the periods of which vary between $\frac{1}{5}$ and $\frac{1}{20}$ of a second. These are recorded by seismographs, and are noticed by certain of the lower animals like pheasants, which before the occurrence of movement perceptible to human beings scream as if alarmed. When an earthquake is preceded by a sound we have evidence of preliminary tremors even more rapid than those recorded by seismographs. Following these precursors there is a shock or shocks, the period of which will be 1 or 2 seconds. From this climax the movements, although irregular in character, become slower and smaller until finally they are imperceptible. The duration of a small earthquake usually varies from a few seconds to a minute, but large earthquakes, which are accompanied by surface undulations, may be felt for 2 or 3 minutes, whilst an ordinary seismograph indicates a duration of from 6 to 12 minutes. A free horizontal pendulum tells us that with severe earthquakes the ground comes

to rest by a series of more or less rhythmical surgings continuing over 1 or 2 hours. Although the maximum displacement has a definite direction, the successive vibrations are frequently performed in many different azimuths. The predominating direction at a given station in certain instances is apparently at right angles to the strike of the neighbouring strata, this being the direction of easiest yielding.

Earthquake motion as recorded at stations several thousands of miles distant from its origin exhibits characteristics strikingly different from those just described. The precursors now show periods of from 1 to 5 seconds, whilst the largest movements corresponding to the shocks may have periods of from 20 to 40 seconds. The interval of time by which the first tremors have outraced the maximum movement has also become greater. Within a few hundreds of miles from an origin this interval increases steadily, the velocity of propagation of the first movements being about 2 km. per second, whilst that of the latter may be taken at about 1·6 km. per second. Beyond this distance the velocity of transmission of the first movements rapidly increases, and for great distances, as for example from Japan to England, it is higher than we should expect for waves of compression passing through steel or glass. This observation precludes the idea that these preliminary tremors have travelled through the heterogeneous crust of the earth, and since the average velocity of their transmission increases with the length of the path along which they have travelled, and we but rarely obtain certain evidence that a seismograph has been disturbed by waves which have reached it by travelling in opposite directions round the world, we are led to the conclusion that earthquake precursors pass through our earth and not round its surface. The following table relating to earthquakes which originated off the coast of Borneo on 20th and 27th September 1897, is illustrative of the velocities here considered:—

***Velocity.***

| Localities. | Distance from origin in degrees. | Velocity in kms. per sec. if on chord. | $\frac{1}{4}\sqrt{\text{Average depth of chord in kms.}}$ |
|---|---|---|---|
| Nicolaieff . . . . | 81° | 8·1 | 8·0 |
| Potsdam . . . . . | 92° | 8·4 | 9·1 |
| Catania, Ischia, Rocca di Papa, Rome . . . | 96° | 9·0 | 9·5 |
| Isle of Wight . . . | 103° | 9·8 | 10·2 |

The chords referred to here are those joining the earthquake origins and distant observing stations, and it will be noted that one-quarter of the square root of the average depths at which these run closely corresponds to observed average velocities if wave paths followed chords. This increase of velocity with average depth shows that the paths followed through the earth must be curved with their convexity towards the centre of the earth. These observations do not directly tell us to what extent a true wave path is deflected from the direction of a chord, but they suggest as an extremely plausible assumption that the square of the speed is a linear function of the depth below the surface of the earth. With this assumption Dr C. G. Knott shows that the square of the speed ($v^2$) can be expressed linearly in terms of the average depth of the chord $d$, thus: $v^2 = 2{\cdot}9 + {\cdot}026\ d$, the units being miles and seconds. The formula applies with fair accuracy to moderate and high values of $d$, but it gives too high a value for short chords. It follows that the square of the speed increases 0·9 per cent. per mile of descent in the earth. The conclusion we arrive at is that the preliminary tremors which pass through the earth do so in the vicinity of their origin at the rate of almost 2·3 km. per second. This velocity increases as the wave path plunges downwards, attaining in the central regions a velocity of 16 to 17 kms., whilst the highest average velocity which is across a diameter lies between 10 and 12 kms. per second.

The large surface waves radiating from an origin to a distant place have velocities lying between 1·6 and 4 kms. per second, and it has been observed that when the higher velocity has been noted this refers to an observation at a station very remote from the origin. One explanation of this is the assumption that only very large waves indicating a large initial disturbance are capable of travelling to great distances, and, as pointed out by Mr R. D. Oldham, large waves under the influence of gravity will travel faster than small waves. These waves (which may be gravitational or distortional) are recorded as slow tiltings of the ground measured by angles of 0·5 to 10 or 15 seconds of arc, or as horizontal displacements of 0·5 or several millimetres. Their calculated lengths have reached 50 kms. (31 miles).

***Frequency.***

In the section of this article relating to the cause of earthquakes a little has been said about their frequency or the number of times these phenomena are repeated during a given interval of time. It has been shown that all countries are very often moved by earthquakes which have originated at great distances. Great Britain, for example, is crossed about 100 times a year by earthquake waves having durations of from 3 minutes to 3 hours, whilst the vibratory motions which originate in that country are not only small but of rare occurrence. In the earlier stages of the world's history, because the contraction of its nucleus was more rapid than it is at present, it is commonly inferred that phenomena accompanying bradyseismical activity must have been more pronounced and have shown themselves upon a grander scale than they do at the present time. Now, although the records of our rocks only carry us back over a certain portion of this history, they certainly represent an interval of time sufficiently long to furnish some evidence of such enfeeblement if it ever existed. So far from this being the case, however, we meet with distinct evidences in the later chapters of geological history of plutonic awakenings much more violent than those recorded at its commencement. During Palæozoic times many mountain ranges were formed, and accompanying these orogenic processes there was marked volcanic activity. In the succeeding Secondary period plutonic forces were quiescent, but during the formation of the early Tertiaries, when some of the largest mountain ranges were created, they awoke with a vigour greater than had ever been previously exhibited. At this period it is not improbable that Scotland was as remarkable for its volcanoes and its earthquakes as Japan is at the present day. If the statement relating to the general decrease in bradyseismical changes referred merely to their frequency, and omitted reference to their magnitude, the views of the geologist and physicist might harmonize. One explanation for this divergence of opinion may rest on the fact that too little attention has been directed to all the conditions which accompany the adaptation of the earth's crust to its shrinking nucleus. As the latter grows smaller the puckerings and foldings of the former should grow larger. Each succeeding geological epoch should be characterized by mountain formations more stupendous than those which preceded them, whilst the fracturing, dislocation, caving-in of ill-supported regions, and creation of lines of freedom for the exhibition of volcanic activity which would accompany these changes, would grow in magnitude. The written records of many countries reflect but on a smaller scale the crystallized records in their hills. In 1844, at Comrie, in Perthshire, as many as twelve earthquakes were recorded in a

single month, whilst now there are but one or two per year. Earthquake frequency varies with time. A district under the influence of hypogenic activities reaches a condition of seismic strain which usually is relieved rapidly at first, but subsequently more slowly.

The small shocks which follow an initial large disturbance are known as after-shocks. The first shock which in 1891 devastated Central Japan was accompanied by the formation of a large fault, and the 3364 small shocks which succeeded this during the following two years are regarded as due to intermittent settlements of disjointed material. The decreasing frequency with which after-shocks occur may be represented by a curve. Dr F. Omori points out that the continuation of such a curve gives the means of determining the length of time which will probably elapse before the region to which it refers will return to the same seismic quiescence that it had prior to the initial disturbance.

***Periodicity.*** The positive results that we have respecting the periodicity of earthquakes are but few. Generally earthquakes are somewhat more frequent during winter than during summer, and this applies to both the northern and southern hemispheres. This annual periodicity, which, however, does not show itself if only destructive earthquakes are considered, finds an explanation, according to Dr Knott, in the annual periodicity of long-continued stresses, as for example those due to the accumulation of snow and to barometric gradients. For certain earthquake regions there appears to be a distinct semi-annual period for which no satisfactory explanation has yet been adduced. Although the elaborate registers of Japan, which have enabled us to group earthquakes according to their respective origins and varying intensities, and to separate after-shocks from initial disturbances, have been subjected by Dr Knott to most careful analysis, with the object of discovering periodicities connected with the ebb and flow of the tides, the lunar day or lunar months, nothing of marked character has been found. Certainly there is slight evidence of a periodicity connected with the times of conjunction and opposition of the sun and moon, and a maximum frequency near the time of perigee, but the effect of lunar stresses is comparatively insignificant. Ordinary earthquakes, and especially after-shocks, show a diurnal period, but we cannot say that there are more earthquakes during the night than during the day.

***Magnetic phenomena.*** Many experiments and investigations have been made to determine a possible relationship between earthquakes and electrical phenomena, but beyond drawing attention to the fact that luminous appearances may accompany the friction of moving masses of rock, and that a temporary current may be established in a line by the disturbance of an earth plate, these inquiries have yielded but little of importance. The inquiries respecting a possible relationship between adjustments so frequently taking place within and beneath that region called the crust of the earth and magnetic phenomena are, however, of a more promising nature. We have seen that at or near the origin of earthquakes which for several hours disturb continents, and occasionally cause oceans to oscillate for longer periods, we sometimes have direct evidence of the bodily displacement of many cubic miles of material. When this material is volcanic it is almost invariably magnetic, and we perceive in its sudden rearrangement causes which should produce magnetic effects within an epifocal district. In Japan, where attention is being directed to phenomena of this description, not only have such effects been observed, but unusual magnetic disturbances have been noted prior to the occurrence of large earthquakes. These may, of course, be regarded as mere coincidences, but when we consider volcanic and seismic activities as evidences of physical and chemical changes, together with mechanical displacements of a magnetic magma, it is reasonable to suppose that they should have at least a local influence upon magnetic needles. Another form of disturbance to which magnetic needles are subjected is that which accompanies the passage of large earth-waves beneath certain observatories situated at great distances from earthquake origins. At Utrecht, Potsdam, and Wilhelmshaven the magnetographs are frequently disturbed by seismic waves, whilst at many other European observatories such effects are absent or only barely appreciable. To explain these marked differences in the behaviour of magnetic needles at different stations we are at present only in a position to formulate hypotheses. They may be due to the fact that different needles have different periodic times of oscillation; it is possible that at one observatory the mechanical movements of the ground are much greater than at others; we may speculate on the existence of materials beneath and around various observatories which are different in their magnetic characters; and, lastly, we may picture a crust of varying thickness, which from time to time is caused to rise and fall upon a magnetic magma, the places nearest to this being the most disturbed.

***Effects on the human mind.*** A subject to which but little attention has hitherto been directed is the effect which displays of seismic and volcanic activities have had upon the human mind. The effects are distinctly dual and opposite in character. In countries like England, where earthquakes are seldom experienced, the prevailing idea is that they are associated with all that is baneful. For certain earthquakes, which fortunately are less than 1 per cent. of those which are annually recorded, this is partially true. A disastrous shock may unnerve a whole community. Many become hysterical, and all are seized with terror, behaving for a time as if they have lost their reason. While the shakings continue, the "Ora pro nobis," or its equivalent, will be heard on many sides. Effects of this nature, however, differ in a marked manner with different nationalities. After the shock of 1891, when Japan lost 9960 of its inhabitants, amongst the wounded indications of mental excitement were shown in spinal and other trouble. The cases of tetanus which were found may be attributed to contamination of open sores. Those who had escaped unhurt and were living in ruined buildings, on hearing the sounds which preceded very many hundreds of after-shocks, and realizing the possibility of a repetition of what had gone before, simply rushed for the open, to return a minute or so later laughing and joking at the continued recurrence of so many false alarms. Notwithstanding the lightheartedness of this particular nation, it is difficult to imagine that the long series of seismic effects chronicled in Japanese history, which culminated in 1896 in the loss of 29,000 lives by sea-waves, has been without some effect upon its mental and moral character. Several earthquakes are annually commemorated by special services at temples. In bygone times governments have recognized earthquakes as visitations of an angry deity, whom they have endeavoured to appease by repealing stringent laws and taxes. In other countries the sermons which have been preached to show that the tremblings of the world were visitations consequent on impiety, and the prayers which have been formulated to ward off disasters in the future, far exceed in number the earthquakes which gave rise to them. In 1755 many of the English clergy held the view that Lisbon was destroyed because its inhabitants were Catholics, whilst the survivors from that disaster attributed their misfortune to the fact that they

had tolerated a few Protestant heretics in their midst. To avoid a recurrence of disaster certain of these were baptized by force. In the myths relating to underground monsters and personages that are said to be the cause of earthquakes we see the direct effects which exhibitions of seismic and volcanic activity have produced upon the imagination. The beliefs, or more properly, perhaps, the poetical fancies thus engendered have exhibited themselves in various forms. Beneath Japan there is said to be a catfish, which in other countries is replaced by a mole, a hog, an elephant, or other living creature, which when it is restless shakes the globe. The Kamchadales picture a subterranean deity called Tuil, who in Scandinavian mythology is represented by the evil genius Loki. To come still nearer home, we have only to think of the reference in the Decalogue forbidding the making of graven images of that which is in the earth beneath, to see in early Biblical history evidence of a subterranean mythology. It cannot be positively stated how this arose, but it seems probable that the same causes which led to the creation of Pluto, Vulcan, and Poseidon gave rise to practices condemned by Moses. The marked effect which these imaginary deities and creatures have had upon the literature and the pictorial and other arts of many nations hardly requires comment. The mental effects which accompany and follow small earthquakes may be compared to those we pay for when we ride upon a switchback. When an earthquake commences there is perhaps a little anxiety as to what may happen next, but when it is over the imagination is excited as to its cause, and there is a feeling of satisfaction that a new sensation has been experienced. Small earth-shiverings have often thawed the formalities of a dinner-party, and made strangers in hotels acquainted with each other.

***Building to withstand earthquakes.***

Perhaps the greatest practical benefits derived during the last few years from seismological investigations relate to important changes and new principles which have been introduced into the arts of the engineer and builder when constructing in earthquake countries. The new rules and formulæ, rather than being theoretical deductions from hypotheses, are the outcome of observation and experiment. True measures of earthquake motion have been given to us by modern seismometers, with the result that seismic destructivity can be accurately expressed in mechanical units. From observation we now know the greatest acceleration and maximum velocity of an earth particle likely to be encountered; and these are measures of the destructivity. The engineer is therefore dealing with known forces, and he has to bear in mind that these are chiefly applied in a horizontal direction. A formula connecting the acceleration requisite to overturn bodies of different dimensions has been given. The acceleration which will fracture or shatter a column firmly fixed at its foundation to the moving earth may be expressed as follows:—

$$a = \frac{1}{6} \cdot \frac{g\text{FAB}}{fw},$$

where

$a$ = the acceleration per sec. per sec.

F = the force of cohesion, or force per unit surface, which when gradually applied produces fracture.

A = area of base fractured.

B = thickness of the column.

$f$ = height of centre of gravity of column above the fractured base.

$w$ = the weight of the portion broken off.

With this formula and its derivatives we are enabled to state the height to which a wall, for example, may be built capable of resisting any assumed acceleration. Experience has shown that yielding first shows itself at the base of a pier, a wall, or a building, and it is therefore clear that the lower portion of such structures should be of greater dimensions or stronger than that above. Piers having these increased dimensions below, and tapering upwards in a proper manner, so that every horizontal section is sufficiently strong to resist the effects of the inertia of its superstructure, are employed to carry railways in Japan. In that country cast-iron piers are things of the past, whilst piers of masonry, together with their foundations, no longer follow the rules of ordinary engineering practice.

After flood, fire, earthquake, or when opportunity presents itself, changes are introduced in the construction of ordinary buildings. In a so-called earthquake-proof house, although externally it is similar to other dwellings, we find rafters running from the ridge pole to the floor sills, an exceedingly light roof, iron straps and sockets replacing mortices and tenons, and many other departures from ordinary rules. Masonry arches for bridges or arched openings in walls (unless protected by lintels), heavy gables, ornamental copings, cappings for chimneys, have by their repeated failure shown that they are undesirable features for construction in earthquake countries. As sites for buildings it is well to avoid soft ground, on which the movement is always greater than on hard ground. Excessive movement also takes place along the face of unsupported openings, and for this reason the edges of scarps, bluffs, cuttings, and river banks are localities to be avoided. In short, the rules and precautions which have to be recognized so as to avoid or mitigate the effects of earthquake movement are so numerous that students of engineering and architecture in Japan receive a special course of lectures on this subject. When it is remembered that a large earthquake may entail a loss of life greater than that which takes place in many wars, and that for the reconstruction of ordinary buildings, factories, and public works an expenditure of several million pounds sterling is required, the importance of these studies cannot be overrated. Severe earthquakes are fortunately unknown in the British Isles, but we have simply to turn our eyes to earthquake-shaken colonies and lands in close commercial touch with Great Britain to realize the importance of mitigating such disasters as much as possible, and any endeavour to obviate the wholesale destruction of life should appeal to the civilized communities of the world.

***Applications of seismometry.***

An unexpected application of seismometry has been to record the vibration of railway trains, bridges, and steamships. An instrument of suitable construction will give records of the more or less violent jolting and vibratory movements of a train, and so localize irregularities due to changes in the character of ballast and sleepers, to variation in gauge, &c. An instrument placed on a locomotive throws considerable light upon the effects due to the methods of balancing the wheels, and by alterations in this respect a saving of fuel of from 1 to 5 lb of coal per mile per locomotive has sometimes been effected.

By mapping the centres from which earthquakes originate off the coast of Japan, we have not only determined districts where geological activity is pronounced, but have placed before the cable engineer well-defined localities which it is advisable to avoid; and in the records of unfelt earthquakes which originate far from land similar information is being collected for the deeper parts of the oceans. Occasionally these records have almost immediately made clear the cause of a cable failure. From lack of such information in 1888, when three cables

connecting Australia with the outer world were simultaneously broken, the sudden isolation was regarded as a possible operation of war, and the colonists called out their naval and military reserves. Records of earthquakes originating at great distances have also frequently enabled us to anticipate, to correct, to extend, or to disprove telegraphic accounts of the disasters. Whatever information a seismogram may give is certain, whilst the information gathered from telegrams may in the process of transit become exaggerated or minimized. Otherwise unaccountable disturbances in records from magnetographs, barographs, and other instruments employed in observatories, are frequently explained by reference to the traces yielded by seismometers. Perhaps the greatest triumph in seismological investigation has been the determination of the varying rates at which motion is propagated through the world. These measurements have already thrown new light upon its effective rigidity, and if we assume that the density of the earth increases uniformly from its surface towards its centre, so that its mean density is 5·5, then, according to Knott, the coefficient of elasticity which governs the transmission of preliminary tremors of an earthquake increases at a rate of nearly 1·2 per cent. per mile of descent. These, then, are a few of the results which seismologists have attained, and considering how much has been accomplished during the last few years, we may surely claim for the study of the changes in progress within the planet on which we live as much attention as is devoted to the study of the ocean, the atmosphere, and the stars.

**East Africa, British.**—British East Africa, in its widest sense, includes all the territory placed under British influence on the eastern side of the continent between the latitudes, roughly speaking, of 6½° S. and 10° N. It is bounded on the S. by German East Africa, on the W. by the Congo State, and on the N., where its limits are still in part undefined, by the Egyptian Sudan, Abyssinia, and Italian Somaliland. The total area is estimated at about 670,000 square miles. Administratively it comprises the protectorates of Zanzibar (consisting of the islands of Zanzibar and Pemba), British East Africa, and Uganda. Apart from a narrow belt of lowlands along the coast, the mainland area, which extends from the Umba river in the south to the Juba in the north, belongs almost entirely to the great lake plateau of East Africa, rarely falling below an elevation of 2000 feet, while extensive sections rise to a height of 6000–8000 feet. The primary surface features run generally in zones from north to south. From the coast lowlands a series of steps with intervening plateaux leads to a broad zone of high ground remarkable for the abundant traces of volcanic action. This broad upland is furrowed by the great East African "rift-valley," formed by the subsidence of its floor, and occupied in parts by lakes without outlet. Towards the west a basin of lower elevation is partially occupied by Victoria Nyanza, drained north to the Nile, while still farther inland the ground again rises to a second volcanic belt, culminating in Mount Ruwenzori (18,000 feet), and traversed by a line of depression occupied by Lakes Albert Edward and Albert, the Western Nile reservoirs. The western boundary of British East Africa is mainly formed, beyond the western rift-valley, by the crest of the watershed between the Nile and Congo basins.

*Coast Zone and Eastern Plateaux.*—The first of the parallel zones—the coast plain or "Temborari"—is generally of insignificant width, varying from 2 to 10 miles, except in the valleys of the main rivers. It consists largely of coral rock partially covered with deposits of alluvium or sand, the latter forming ridges sometimes 400 feet high. The shore line is broken by bays and branching creeks, often cutting off islands from the mainland. Such are Mvita or Mombasa in 4° 5′ S., and the larger islands of Lamu, Manda, and Patta, between 20° 20′ and 2°. Farther north the coast becomes straighter, with the one indentation of Port Durnford in 1° 10′ S., but skirted seawards by a row of small islands. The northern interior east of the rift-valley is still little known, and a detailed description must therefore be confined to the more southern parts. Beyond the coast plain the country rises in a generally well-defined step or steps to an altitude of some 800 feet, forming the wide level plain of the "Nyika" (uplands), largely composed of quartz. In the south this zone has a width of some 80 miles, but it widens out northwards, and seems to occupy a large part of the northern interior. The next stage in the ascent is marked by an intermittent line of mountains—gneissose or schistose—running generally north-north-west, sometimes in parallel chains, and representing the primitive axis of the continent. Their height varies from 5000 to 8000 feet. The principal units are the Bura Mountains in 3¼° to 3½° S., the Julu or Dyulu range between 2¼° and 2¾° S., the Iveti Mountains in 1½° S., and various ranges in the districts of Kikuyu and Ukamba. East of the latter the plateau itself seems to consist of a wide extent of grass. Farther inland wide uplands, largely grass-covered, and known to the inhabitants as Rangatan, extend to the eastern edge of the rift-valley, though varied with cultivated ground and forest, the former especially in Kikuyu, the latter between 0° and 0° 40′ S. The most extensive grassy plains are those of Kapte or Kapote and Athi, between 1° and 2° S. The general altitude of these uplands, the surface of which is largely composed of lava, varies from 5000 to 8000 feet, the highest portion occurring on or near the equator, beyond which the high Laikipia plateau falls gradually to the north. This zone contains the highest elevations in British East Africa, including the volcanic pile of Kenya (17,200 feet), Settima (13,400 feet), and Nandarua (12,900 feet). To the west the fall to the rift-valley is marked by a line of cliffs, of which the best defined portions are the Kikuyu escarpment (800 feet), just south of 1° S.; the Kinangop escarpment, a little north of the same parallel; the Laikipia escarpment, on the equator; and the cliffs of Morongop, a little south of 1° N. In the intervals the descent is often much more gradual.

*Rivers of the East Coast.*—One of the main watersheds of East Africa runs in close proximity to this eastern wall of the rift-valley, separating the basins of inland drainage from the rivers of the east coast, of which the two largest, wholly within British East Africa, are the Sabaki and Tana. The Sabaki rises (as the Athi) in 1° 42′ S., and after flowing north-east for 70 miles across the Kapote and Athi plains, turns south-south-east under the wooded slopes of the Yatta ridge, which shuts in its basin on the east. In 3° S. it turns east, and in its lower course (known as the Sabaki) traverses the sterile quartz-land of the outer plateau. The actual valley is in parts low and flat, covered with forest and scrub, and containing small lakes and backwaters connected with the river in the rains. At this season the stream is deep and strong, and of a turbid yellow colour, but navigation is interrupted by the Lugard falls, about 100 miles from its mouth. Its total length is about 400 miles, but, apart from the numerous small feeders of the upper river, almost the only tributary is the Tzavo, from the

east side of Kilimanjaro, which enters in about 3° S. The Tana is both longer and larger than the Sabaki. One series of its numerous headstreams traverses the Kikuyu plateau north of the Athi, while others flow down the southern and eastern slopes of Kenya, uniting with the former to form the Kiloluma, a rapid stream traversing a broken rocky country, with many falls. Beyond 39° E. no tributary of any importance is known to join the main stream, which flows in a wide curve east and south, its course being very tortuous, the current rapid, and the channel much obstructed by snags. Its width varies, as a general rule, between 100 and 200 yards. The banks are generally low, in part forested and inundated at high water, but away from the river the country appears to consist of dry plains covered with mimosa scrub. Adjoining the Lower Tana are many backwaters, which seem to show that the course has been subject to great changes. In 2° 20′ S. the river again turns east, but during the last 10 miles it flows south-west, parallel to the coast, finally entering the sea across a dangerous bar. Some 20 miles from the mouth the narrow Belasoni canal connects the Tana with the Ozi, the intervening country being deltaic in character, and at high water a discharge takes place in this direction. Observations made at Golbanti by the Rev. W. Ormerod show that the Tana rises twice in the year, being high in June and July and again in November and December, these periods coinciding with the rainy seasons in the Kenya region.

*The Eastern Rift-Valley.*—Coming next to the rift-valley, this, though with a generally level floor, is divided by transverse ridges into a series of basins, each containing a lake without outlet. The southernmost section within British East Africa is formed by the arid Dogilani plains, drained south towards German territory. At their north end rise the extinct volcanos of Suswa (7800 feet) and Longonot (8700), the latter on the ridge dividing off the next basin—that of Lake Naivasha. This is a small fresh-water lake, 6312 feet above the sea, measuring some 13 miles each way. Its basin is closed to the north by the ridge of Mount Buru, beyond which is the basin of the still smaller Lakes Nakuro (5845 feet) and Elmenteita (5860 feet), followed in turn by that of Baringo. This lake (15 miles long by 8 broad, altitude 3300 feet) lies at the north end of the basin, the southern parts being drained north by the Nyuki river, which, however, is lost in a swamp just before reaching Baringo. At the foot of the eastern escarpment, and separated from the Baringo basin by subsidiary ridges, are Lakes Kibibi (4820 feet) and Losuguta (3050 feet). Beyond Baringo the valley is again drained north into Lake Sugota, in 2° N., some 35 miles long, while north of this lies the much larger Lake Rudolf, the valley becoming here somewhat less defined.

*The Western Escarpments and Plateaux.*—On the west of the rift-valley the wall of cliffs is best marked between the equator and 1° S., where it is known as the Mau escarpment, and about 1° N., where the Elgeyo escarpment falls to a longitudinal valley separated from Lake Baringo by the ridge of Kamasia. Opposite Lake Naivasha the total height of the Mau escarpment is some 3000 feet. At the top occurs a vast forest, in great part unexplored. To the south the woods become more open, and the plateau falls towards an open country drained towards the Dogilani plains. On the west the cultivated districts of Sotik and Lumbwa, broken by wooded heights, fall towards Victoria Nyanza. The Mau plateau reaches a height of 9000 feet on the equator, north of which is the somewhat lower Nandi country, well watered and partly forested. In the treeless "red-plain" of Guash Ngishu, abreast of Elgeyo, it again rises to a height of over 8000 feet, and to the west of this is the great mountain mass of Elgon. All these plateaux west of the rift-valley are included in the Uganda Protectorate.

*Climate, Fauna, Flora.*—In its climate and vegetation British East Africa again shows an arrangement of zones parallel to the coast. Close to the sea, where the rainfall is fairly plentiful, the low plain is covered with thick bush. The outer plateaux, especially the "Nyika," have a scanty rainfall, and form arid steppes with a sparse scrub vegetation. The uplands beyond are generally fertile, clothed with rich pastures alternating with cultivated ground and forest, the latter covering a large part of the Mau plateau. Farther west the rainfall increases, and in Uganda and neighbouring countries cultivated land and pasture are varied with luxuriant groves of bananas, which form a chief item in the food of the inhabitants. The higher mountains have a distinct flora, representing the remnants of the flora of a cooler period. Large mammals are plentiful, especially on the drier steppes. They include the elephant (more and more restricted to unfrequented districts), rhinoceros, many kinds of antelope, giraffe, hippopotamus, lion and other carnivora. In many parts the rhinoceros is particularly abundant and dangerous.

*Natives.*—The inhabitants include representatives of various stocks, as the country forms a borderland between the Negro and Hamitic races, and contains many tribes of mixed or doubtful affinities. The Bantu division of the former is represented chiefly in the south, the principal tribes being the Wakamba, Wakikuyu, Wa-Giriama, Wapokomo, Waboni, &c. In the west the Bantu peoples (Waganda, Wanyoro, &c.) have been subject to intruders of Galla stock (Wahuma), who are cattle-rearers, while the subject population practise agriculture. In the north-west—on the Upper Nile—the tribes are more nearly related to the true Negroes, though sometimes placed in a distinct group as "Nilotic." Of Hamitic race are the Masai, a race of cattle-rearers speaking a Nilotic language, who in decreasing numbers occupy the uplands bordering on the eastern rift-valley. Farther north they are represented by the Turkana and other tribes dwelling between Lake Rudolf and the Nile. A section of the Masai, which has adopted the settled life of agriculturists, is known as the Wakwafi. The Galla section of the Hamites is represented, among others, by the Borans of the plains east of Lake Rudolf, while Somalis occur in the coast-lands between the Tana and Juba rivers. Primitive hunting tribes are the Wandorobo in Masailand and scattered tribes of small stature in various parts. The immediate coast-land contains a mixed population of Arab and Hindu immigrants, with representatives of numberless interior tribes. Missions have been at work for many years, both on the coast and in the Uganda region, and increasing numbers of native children are being educated in mission schools.

*Annexation and Administration.*—The Portuguese held posts on the coast during the 16th and 17th centuries, but finally abandoned Mombasa in 1729. The interior was first made known in the middle of the 19th century by the journeys of Krapf, Rebmann, Von der Decken, and others, followed a little later by the great expedition of Speke and Grant to the Upper Nile region. The countries east of Victoria Nyanza (Masailand, &c.) were, however, first traversed throughout their whole extent by Joseph Thomson in 1883–84.[1] When, almost immediately afterwards, Germany secured a footing on the coast opposite Zanzibar, a British claim, ratified by an agreement with Germany in 1886, was made to the districts behind Mombasa, the administration of the coast towns being ceded by the sultan of Zanzibar. In 1888 the British East Africa Company obtained a charter placing the government of the territory in its hands, but, after doing much to open up the country, and securing Uganda for Great Britain, was forced by lack of resources to make over its rights to the British Government (1895). Uganda was then declared a British protectorate, and in 1896 the districts between the latter and the coast were formally taken over by the Foreign Office as the British East Africa Protectorate. The islands of Zanzibar and Pemba had been taken over in 1890 by agreement with Germany.

*British East Africa Protectorate.*—The British East Africa Protectorate, which, roughly speaking, extends to the rift-valley, has been divided into the four provinces of Seyyidieh (the coast province, capital Mombasa), Ukamba (capital Nairobi), Tanaland (capital Lamu), and Jubaland (capital Kismayu), each being in turn divided into districts and subdistricts. These are—in Seyyidieh, districts: Vanga, Mombasa, and Melindi; subdistricts, Rabai and Takaungu. In Ukamba, districts: Teita, Kitui, Masailand, Ulu, and Kenya; subdistricts, Kikumbului and Taveta. In Tanaland, districts: Lamu, Port Durnford, and Tana river. In Jubaland, districts: Upper and Lower Jubaland. The area (apart from the northward extension not yet organized or under control) is estimated at 80,000 square miles, and population 2,500,000, including 25,000 Asiatics and 450 Europeans and Eurasians. The revenue

[1] For further details on exploration, see AFRICA.

for 1897–98 amounted to £43,481; for 1898–99, to £69,400; and for 1899–1900 was estimated at from £75,000 to £80,000. The capital of the protectorate is Mombasa, which is also the largest town (population, 27,000). It has two excellent harbours, one on each side of the island of Mvita or Mombasa, on the eastern side of which the town is placed. The harbour on the south-west side is known as Port Kilindini, and here, on the west side of the island, is the terminus of the Uganda Railway, with a pier and other works. On the mainland, nearly opposite Mombasa town, is the settlement of freed slaves called Freretown, after Sir Bartle Frere. The second largest town is Lamu, on the island of the same name, besides which the most important are Melindi, Patta, Kipini, Port Durnford, and Kismayu. Much has been done to open up the country by means of roads, including a trunk road from Mombasa by Kibwezi in the upper Sabaki basin and Lake Naivasha to Berkeley Bay on Victoria Nyanza. But the most important work taken in hand is the construction of a railway from Mombasa to that lake, for which a survey was executed in 1892, and on which work was commenced in 1896. The line chosen roughly coincides with that of the road just mentioned, until the equator is reached, after which it will strike by a more direct route across the Mau plateau to Lake Victoria, which it will reach at Port Florence on Kavirondo Bay; total length, 582 miles. The most serious difficulty has been the descent of the escarpment of Kikuyu to the rift-valley, which has necessitated the most skilful engineering. The total length of the line constructed up to April 1901 was 488 miles.

*Resources and Commerce.*—The resources of British East Africa are still little developed. The coast-lands, however, contain much fertile soil suitable for the cultivation of cotton, jute, the cocoanut, oil-seeds, fibres, &c., while the jungle products include rubber, copal, orchilla, &c. The grassy uplands of the interior are eminently suited for cattle-rearing, and at the higher elevations European crops might be grown with success. The comparative healthiness of these plateaux might possibly allow of their settlement by white men. The imports, which in 1897–98 reached a total of about 4½ million rupees, and in 1898–99 about 7 millions, were valued at 6,642,000 rupees in 1899–1900; the exports, which in the former two years were little over 1 million rupees, in 1899–1900 rose to 1,825,000. The chief articles imported are piece and trade goods, rice, grain, and flour, while the exports consist principally of ivory (which showed a large increase in 1899–1900), rubber, hides and horns, and grains. Shipping entered, in 1897–98, to the extent of 196,630 tons; in 1898–99, 321,440 tons; in 1899–1900, 332,882 tons.

(E. HE.)

**East Africa, German,** occupying the east centre of the African continent, was acquired for Germany by treaties which Dr Peters, Graf Pfeil, and Dr Jühlke concluded with a number of chiefs in November and December 1887. An imperial charter was granted on the 27th of February 1885, and on the 28th of October 1890 the sultan of Zanzibar ceded his suzerainty over the coast and the island of Mafia to the German emperor. The protectorate extends from 1° S. lat. to 11° S. lat. and 30° to 40° E. long. On the E. it is bounded by the Indian Ocean, on the N.E. and N. by British East Africa. The boundary line runs from the mouth of the Umbe river to Lake Jipe and Mount Kilimanjaro, including both in the protectorate, and thence to Victoria Nyanza, crossing it on 1° S. lat., which parallel it follows till it reaches 30° E. long. On the 1st of July 1890 it was stipulated that this line should be subject to an alteration in case it included Mount Mfumbiro, which was to fall into the British sphere of influence. In the west it is separated from the Congo Free State as follows, according to the agreement of 1st to 25th August 1885. From the point of intersection of 1° S. lat. and 30° E. long., nearly straight to the north end of Lake Tanganyika, along the middle line of the lake to where this is intersected by the south boundary line of the Congo Free State in about 8° 30′ S. lat. In November 1900 a disputed boundary on Lake Kivu was decided by the King of the Belgians in favour of Germany. The agreement of 30th July 1890 arranged the boundary between Lakes Tanganyika and Nyasa as follows. From Tanganyika along the river Kilamba to the junction of its two arms; thence in a line which is not fixed with absolute precision to the point where 35° E. long. intersects the river Songwe, which it follows to the lake. Round the northern end it follows the shore of the lake, which it leaves on that degree of S. lat. on which the river Msinge enters the Rovuma; joining these two points, it follows the latter river to the Indian Ocean, according to the agreement between Portugal and Germany of 30th December 1886. These boundaries include an area of about 385,000 square miles, with a population roughly estimated at 3,000,000 to 8,000,000.

*Physical Features.*—The coast of German East Africa is chiefly composed of coral, and is generally low, partly sandy, partly covered with bush or mangroves. Only where the Arabs have established settlements the cocoa-palm and mango tree introduced by them give character to the vegetation. The coast, though little indented, has several good harbours, amongst them Tanga (5000), Dar-es-Salaam (13,000), Kilwa (10,000), Kisiwani, Lindi, Mikindani, Bagamoyo (13,000). The littoral plain is from 10 to 30 miles wide and 620 miles long; it is bordered on the west by the precipitous eastern side of the interior plateau of Central Africa. As a whole this plateau, considerably tilted from its horizontal position, attains its highest elevation north of Lake Nyasa, where several peaks rise to 8000 feet, one to 9000, while its mean altitude is about 3000 to 4000 feet. From this region the country slopes gently towards the north-west, and is not distinguished by any considerable mountain ranges. A deep narrow gorge, the so-called "rift-valley," traverses the middle of the plateau in a meridional direction. In the northern part of the country it spreads into several side valleys, from one of which rises the extinct volcano Mount Kilimanjaro (19,200 feet), the highest mountain in all Africa. Its glacier sends down a thousand rills which combine to form the Pangani river. East of Mount Kilimanjaro are the Paré Mountains, separated from the coast only by a comparatively narrow strip of plain. The Pangani is navigable for 12 to 18 miles, the Rufiji for more than 60 miles from the coast, and its tributary, the Ulanga, for a much greater distance. The Wami and Kingani spring from the plateau border and the mountains fringing it; only the latter river has been ascended by a steam launch. The Rovuma, though broader than the other rivers, is very shallow, so that all attempts at navigation have proved failures. West of the rift-valley the plateau sends its water through the Malagarazi to Lake Tanganyika and thence to the Atlantic, through the Kagera and other smaller rivers to Lake Victoria and the Nile. Lake Nyasa in the southern part of the country and Lake Tanganyika fill the deepest part of the Central African rift-valley. Several smaller lakes occur in parts of the eastern rift. Lake Rikwa is presumably only the remnant of a huge swamp, the extent of which varies with the rainfall of each year. Lake Victoria, the largest of all African lakes, is the reservoir which gives rise to the Nile.

*Meteorology.*—The climate derives its chief characteristic from the monsoons. On the coast the south-east monsoon sets in in April,

and the north-east monsoon in November. In the interior April brings south-east winds, which continue until about the beginning of October. During the rest of the year changing winds prevail. These winds are charged with moisture, which they part with on ascending the precipitous side of the plateau. The heat, though scarcely greater here than in the interior, is sometimes oppressive. Rain comes with the south-east monsoon, and on the northern part of the coast the rainy season is divided into two parts, the great and the little Masika: the former falls in the months of September, October, November; the latter in February and March. In the interior the climate has a more continental character, and is subject to considerable changes of temperature; the rainy season sets in a little earlier the farther west and north we proceed, and is well marked, the rain beginning in November and ending in April; the rest of the year is dry. On the highest parts of the plateau the climate is almost European, the nights being sometimes exceedingly cold. Kilimanjaro has a climate of its own; the west and south sides of the mountain receive the greatest rainfall, while the east and north sides are dry nearly all the year. On a mountain of such height all degrees of temperature are to be met with. Malarial diseases are rather frequent, more so on the coast than farther inland. The Kilimanjaro region is said to enjoy immunity. Smallpox is frequent on the coast, but is diminishing before vaccination; cases of other epidemic diseases are extremely rare.

*Flora and Fauna.*—The character of the vegetation varies with and depends on moisture, temperature, and soil. On the low littoral zone the coast produces a rich tropical bush, in which the mangrove is very prominent. Cocoa-palms and mango trees have been planted in great numbers, and also many varieties of bananas. The bush is grouped in copses on meadows, which produce a coarse tall grass. The river banks are lined with belts of dense forest, in which useful timber occurs. The *Hyphæna* palm is frequent, as well as various kinds of gum-producing mimosas. The slopes of the plateau which face the rain-bringing monsoon are in some places covered with primeval forest, in which timber is plentiful. The silk-cotton tree (*Bombax ceiba*), miomba, tamarisk, copal tree (*Hymenæa courbaril*) are frequent, besides sycamores, banian trees (*Ficus indica*), and the deleb palm (*Borassus æthiopum*). It is here we find the *Landolphia florida*, which yields the best rubber. The plateau is partly grass land without bush and forest, partly steppe covered with mimosa bush, which sometimes is almost impenetrable. Mount Kilimanjaro exhibits on a vertical scale the various forms of vegetation which characterize East Africa (see Kilimanjaro). East Africa is rich in all kinds of antelope, and the elephant, rhinoceros, and hippopotamus are still plentiful in parts. Characteristic are the giraffe, the chimpanzee, and ostrich. Buffaloes and zebras occur in two or three varieties. Lions and leopards sometimes stray down to the coast. Crocodiles are found in all the larger rivers. Snakes, many venomous, are frequent. Of birds there are comparatively few on the steppe, but rivers, lakes, and swamps abound with them. Locusts have often been observed in late years, and ants of various kinds are often a plague. The tsetse fly (*Glossina morsitans*) infests several districts; the sand-flea has been imported by labourers returning from the west coast. Land and water turtles are frequent.

*Ethnography.*—On the coast we find Arab and Indian immigrants, who are agriculturists and merchants. The Waswaheli are a tribe sprung from a mixture of these immigrants with Bantu natives. They are Islamites. In the interior can be distinguished two classes of Bantu negroes; one with a migratory tendency towards the north and an addition of Zulu immigrants, the other with a similar tendency towards southward expansion and an admixture of Hamitic and Nilotic elements. The older groups of Bantu are chiefly agriculturists and live in conical houses, while the others comprise the cattle-raising tribes, who live in square mud-plastered houses called *tembe*, which can be easily fortified and defended. The agriculturists are good labourers, and willingly take service with the whites; they form the great caravans. The cattle-raising tribes are less sociably inclined, and often very warlike. In 1891 the rinderpest brought to the verge of ruin those who, like the Masai, would not adopt agriculture as a means of livelihood.

*Government.*—The coast is divided into six districts (*Bezirksaemter*), Tanga, Pangani, Bagamoyo, Dar-es-Salaam, Kilwa, Mikindani. In the interior there are ten stations (*Stationsbezirke*), Victoria Nyanza, Kilimanjaro, Tabora, Kilimatinde, Mpwapwa, Kilossa, Tanganyika, Langenburg, Ulanga, and Lindi. Each station has a chief, who is subordinate to the official of his district, these in their turn being under the governor, who resides in Dar-es-Salaam. The lieutenant-governor is also commander of the colonial force, consisting (1901) of 1635 regular and 168 irregular coloured soldiers, with 44 commissioned, 110 non-commissioned white officers, 12 coloured non-commissioned officers) and 18 medical officers. There are 61 field-guns. The stations have to maintain communication with the native chiefs, and peace in the interior; they have to introduce as far as possible cultivation of valuable products, and to establish and maintain roads. The district chiefs on the coast administer their districts in the ordinary way, with the assistance of a police force and a regular staff of officials. They have to keep an eye on the suppression of slavery and on the regulation of the supply of labour. They are entrusted with the functions of judges in all cases of litigation between coloured people; in cases involving amounts exceeding 1000 rupees, appeal to the governor is admissible. There are two ordinary judges and one chief justice in the colony; the latter conjointly with the governor presides over a court of appeal.

*Finance.*—The revenue is raised by taxes on imports and exports, on consumption and from licences for the sale of spirituous liquors, and wood-cutting, harbour and other dues, and the natives have to pay a hut tax. Receipts for the sale of lands are also beginning to swell the revenue. The expenditure is for civil and military administration, the small fleet of steamers maintained by the colonial government, and the caravans, which keep up communication with the stations in the interior and supply them with European necessaries. In the budget for 1899–1900 the revenue (including Imperial contribution of 5,985,000 marks) and expenditure balanced at 8,495,000 marks. The Imperial contribution for 1900–1901 was 6,830,000 marks.

*Missions.*—There are ten missionary societies—six German, one French, three English. Three of the ten are Roman Catholic. One of the latter, the *Mission du Sacré Cœur* in Bagamoyo, the oldest mission, has been very successful in training young negroes to be useful mechanics. There are several schools, and the number of young people who can read and write is increasing rapidly. On the coast the inhabitants profess to be Moslems.

*Communications.*—The German East Africa line of Hamburg runs a fleet of first-class steamers to East Africa, which touch at Tanga, Dar-es-Salaam, and Zanzibar. Two steamers go to Bombay once in three weeks; and of other lines, the Messageries Maritimes and British East India Steam Navigation Company call once a month at Zanzibar. Proper roads only exist where constant traffic keeps them open. A railway has been laid from Tanga to Korogwe. Regular postal communication is maintained with the stations in the interior, through native runners, twice a month. There is a submarine cable from Dar-es-Salaam to Zanzibar, and an overland line connecting all the coast stations.

*Production.*—The country is rich in natural products which are found in the forest or cultivated by the natives. The former are chiefly rubber, copal, bark, various kinds of fibres, orseille, timber, pepper, honey; the latter cocoanuts, tobacco, sugar-cane, cotton, vanilla, sorghum, panicillaria, eleusine, arachis, sesame, maize, rice, beans, peas, bananas, batatas and yams, manioc and hemp. Animal products are ivory, hides, tortoiseshell, and pearls. On the plateau in the interior large herds of cattle are reared by the natives, who in the lowlands are chiefly agriculturists. The people have many small native smithies. Useful minerals exist, but are not yet exploited. Coal, iron, graphite, and salt have been found, and gold too, though not in paying quantities.

The imports and exports have been as follows, in marks:—

| | 1888. | 1895. | 1898. |
|---|---|---|---|
| Imports . . | 2,485,163 | 7,629,000 | 16,401,705 |
| Exports . . | 4,270,653 | 3,257,584 | 5,995,930 |

The chief exports were ivory, rubber, sesame, and gum.

No sooner was German East Africa annexed than companies were formed for the purpose of exploiting the country by trading, planting, and mining. The first was the Deutsch Oestafricanische Gesellschaft, founded in 1885, which now owns large capital, has trading stations in each seaport, and seven flourishing plantations in various parts of the country. It is the owner of vast tracts of land, which in time are expected to become extremely valuable. No fewer than forty trading companies have been established since then, and all are in a more or less thriving condition; a comparatively large number of private individuals have laid out plantations, from which they are beginning to derive a considerable return. Coffee and tobacco are the chief products, and thrive so well in the northern parts of the littoral zone of the protectorate, that Usambara and Paré have become favourite districts for agricultural enterprise.

**East Africa, Portuguese,** or **Mozambique,** a province of the East Coast of Africa, belonging to Portugal, stretching 1430 miles along the Indian Ocean, between 10° 40′ and 26° 52′ S. lat.

*Boundaries and Physical Geography.*—By treaties with Germany in 1886 and in 1894, and with Great Britain in 1891, the boundaries are as follow:—On the N. by 10° 40′ S. lat. to the Rovuma, and this river as far as the confluence of the M'Singe, and thence due W. to the E. shore of Lake Nyasa; on the W. along the E. shore of the lake southwards as far as 13° 30′ S. lat., thence S.E. to the E. shore of Lake Shiuta, along this lake and in a straight line from its S. extremity to the E. side of Lake Shiré, down its E. side to the S. end, and straight on to the most E. affluent (M'losa) of the river Ruo, which stream it then follows as far as its confluence with the Shiré. From that point it coincides with the Shiré as far as a point a little below Shiwanga, thence due W. until it intersects the watershed between the Shiré and the Zambezi; then it follows this watershed, and the watershed between the Zambezi and Lake Nyasa as far as 14° S.; after that it turns S.W. and goes to the point where the river Arwangua is cut by 15° S. lat., and thence follows this river to its confluence with the Zambezi. On the S. of the Zambezi the Portuguese boundary strikes from a point opposite the mouth of the Arwangua and goes due S. to 16° S. lat., which it follows as far as 31° E. long., thence E. to the outer section of the river Mazoe and 33° E. long., continues along this meridian to 18° 30′ S. lat., then follows southwards along the upper edge of the Manica plateau as far as the river Save, and follows the course of this river to its confluence with the Lunde. From that point it makes for the N.E. corner of the Transvaal Colony, then goes S. over the Lebombos and Swaziland frontier to the river Maputo, follows this river to the confluence of the Pongolo, and finally runs thence due E. to the Indian Ocean near Oro Point. Portugal at one time claimed almost unlimited areas in the interior of the continent, but by the extension of British enterprise in the south and west, and German enterprise in the north, the limits of the territory have been defined as above.

Orographically the backbone of the province south of the Zambezi is formed by the Lebombo Mountains, which, however, nowhere exceed 2070 ft. in height; the Manica plateau, where Mount Doe rises to 7875 ft. and Mount Panga to 7610 ft.; and the Gorongosa plateau, with Mount Miranga (6550 ft.), Enhatete (6050 ft.), and Gogogo (5900 ft.). The chief mountain range, however, lies north of the Zambezi, namely, the Namuli Mountains, in which Namuli Peak rises to 8860 ft., and Molisani, Mruli, and Mresi attain to altitudes of 6500 to 8000 ft. These mountains are covered with vegetation and have a temperate and healthy climate, a decided contrast to the unhealthy, malaria-haunted lowlands along the coast. At Tete, on the Lower Zambezi, the annual mean temperature is 77°·9 Fahr.; the hottest month being November, 83°·3, and the coldest July, 72°·5. At Quilimane, on the coast, the mean temperature is 85°·1, maximum 106°·7, and minimum 49°·1. The rainy season lasts from December to March, and the dry season from May to September. During the monsoons the districts bordering on the Mozambique Channel enjoy a tolerably even mean temperature of 76°·1, maximum mean 88°·7, and minimum mean 65°·3. Besides the Zambezi, the principal rivers that water the territory are the Limpopo, Save, Pungwe, Lurio, Rovuma, Shiré, and Luia. In 1891 the colony, which used to be known as Mozambique, was designated the State of East Africa, and was divided into a northern and southern province, Mozambique and Lourenço Marques; and further, instead of that division, into the districts of Mozambique, Zambezia, Gaza, and Inhambane, Lourenço Marques forming one province. There is a governor-general, appointed for three years, residing at Lourenço Marques, now the capital. There is a force of 3180 regular troops. The Manica and Sofala regions are administered by the Mozambique Company, which has a royal charter granting sovereign rights for fifty years from 1891. Another company administers the region on the east of Lake Nyasa, and the Companhia da Zambezia holds a concession in the Quilimane, Tete, and Zumbo regions. For 1900–1901 the estimated revenue was 2,838,000 milreis, and expenditure 2,993,000 milreis.

*Products and Trade.*—The chief vegetable products of the low coast region are the cocoanut and various other palms, ironwood (*Casuarina*), indigo, orchil, tobacco, coffee, and several oleaginous plants. The higher zone above the coast-lands abounds in timber trees, as the *mutembate* and the *morepa*, which yield timber similar to teak; cutch and cedra serve as supports for the climbing *m'bungo* (*L*[illegible] *florida*) and calumba (*Jateorhiza palmata*). The [illegible] their attention chiefly to the cultivation of oleaginous crops, *e.g.*, almonds, sesamum, cocoanuts, copra, cashew nuts, and carapa. At Mopeia and other places the sugar-cane is cultivated. In the north of the province, on the Zambezi, and at Inhambane, rice, millet, and beans are grown, also coffee in the two districts last named; indiarubber in Quilimane. Wheat and other cereals grow in the delta of the Zambezi and in the valley of the Busi. Coal exists chiefly in Tete and between the Rovuma, Lujenda, and M'Salu, in Medo, and alongside the Umbelusi; iron is abundant in the Serra Shinga, and is extracted by the Makwas; gold exists in Medo, Mashinga, Missale, and Manica. In Manica the gold-mining country has been taken up mainly by British subjects. Fish are plentiful along the coast, and pearls are fished in the Bazaruto Isles. Spirits, sugar, and pottery are the only commodities manufactured. The imports in 1898 were valued at £19,894,000, exports at £402,400, besides a transit trade, mainly by Beira and Lourenço Marques, of about £2,500,000. The total trade in 1899 was £29,662,500. Lourenço Marques, Beira, and Chinde are the chief ports. The chief exports are oil, seeds, indiarubber, wax, gum, orchil, coffee, tobacco, Indian hemp, manioc, ivory. The imports (£108,670 from Portugal in 1895, £466,000 in 1897) consist principally of wine, with cottons, woollens, linen, silk, preserved foods, flour, ironmongery. Trade is carried on chiefly with Bombay, Marseilles, England, Zanzibar, and Lisbon. The province possesses only two railways, one running from Lourenço Marques to the Transvaal frontier, 57 miles (Ressano Garcia), and so on to Pretoria, and the other from Beira to the frontier of Rhodesia, 222 miles, and to Salisbury. Beira is connected by telegraph with Salisbury, and Lourenço Marques with the Transvaal system, and there are 2661 miles of line.

*Population, &c.*—The area is estimated at 301,000 square miles, and the population at 3,120,000. Of the native races the most important in the north are the Makwas and the Ajaus, both belonging to the Bantu stock. The dominant race between the Zambezi and the Mazoe are the Tavalas, other tribes in the same region being the Maraves, Sengas, Muzimbas, and Muzuzuros. On the south of the Zambezi the ruling race are the Zulu tribe of the Vatwa in Gasa; all other tribes of different stock being known as Tongas. The province forms a bishopric (Mozambique), belonging to the ecclesiastical province of Goa.

The principal towns are as follow:—Mozambique, the old capital, on an island off the coast to the north of the Zambezi; population about 8000. In 1898 it was visited by 416 vessels, of 188,665 tons. Quilimane or Kelimane, at the mouth of a supposed former branch of the Zambezi, which is silting up. Chinde, a new port at the mouth of the Chinde branch of the Zambezi, in which Great Britain has a lease of land for a bonded warehouse; it is connected by telegraph with Blantyre in British Central Africa; population (1898), 1675. Beira, at the mouth of the Pungwe, south of the Zambezi, connected by rail and telegraph with Salisbury in Mashonaland, and an important port for transit trade with the interior; in 1898, 270 vessels, of 434,684 tons, visited the port; population (1898), 4223. Lourenço Marques, on Delagoa Bay, of importance as the terminus of the railway to the Transvaal, with good harbour and excellent anchorage in the bay; in 1898, 505 vessels, of 1,032,543 tons, visited the port; population, 5130. Towns on the Zambezi of little importance are Zumbo, Tete, and Sena.

**Eastbourne,** a municipal borough (1883) and flourishing watering-place in the Eastbourne parliamentary division of Sussex, England, 65 miles south-south-east of London by rail. The ancient church of St Mary has been restored, and with that there are now eight parish churches, a Roman Catholic and various Nonconformist churches. Recent erections otherwise are the town-hall and municipal buildings, the Princess Alice Memorial Hospital, the children's branch of All Saints' Convalescent Hospital, and a free library. There are also public baths and many high-class schools. The pier has been provided with a handsome pavilion and a new landing stage. Devonshire Park (13 acres) contains a large pavilion and a theatre. Area, 5410 acres. Population (1881), 22,014; (1901), 43,357.

**Easthampton,** a town of Hampshire county, Mass., U.S.A., in the Connecticut valley. It is entered by two railways, and is the seat of Williston Academy. Population (1890), 4395; (1900), 5603, of whom 1731 were foreign-born and 42 negroes.

**East Hartford,** a town of Hartford county, Connecticut, U.S.A., on the Connecticut opposite Hartford, and entered by two railways. Population (1890), 4455; (1900), 6406, of whom 1191 were foreign-born and 78 negroes.

**East Liverpool,** a city of Columbiana county, Ohio, U.S.A., on the Ohio river and on the Pennsylvania railroad, at an altitude of 692 feet. Pottery is the chief manufacture. Population (1880), 5568; (1890), 10,956; (1900), 16,485, of whom 2112 were foreign-born and 219 negroes.

**East London,** a town and seaport of Cape Colony, at the mouth of the Buffalo river, between the Keiskamma and Great Kei estuaries, with a population of about 7000. The harbour is one of the most dangerous on the south coast, and is still often inaccessible for days together, despite the breakwaters and other extensive works that have been constructed to improve the approaches. The bar, which formerly shifted with every storm and freshet, is now fixed, but has seldom more than a depth of 9 or 10 feet at the flow, whereas before the works were carried out it could be crossed by vessels drawing 20 feet of water. Nevertheless East London, being the natural outlet for the rich pasturages of the eastern districts, is the second port in the colony for the shipment of wool. It is the seaward terminus of the railway which runs through Queenstown and Molteno north to the Orange River Colony. The imports, chiefly textiles, hardware, and provisions, were valued at £3,456,000 in 1896, £3,121,000 in 1897, and £3,520,000 in 1898; and the exports (wool, angora hair, hides, and skins) at £851,000, £817,000, and £955,000 for the same years.

**Easton,** capital of Northampton county, Pennsylvania, U.S.A., in 40° 43′ N. lat. and 75° 16′ W. long., at an altitude of 215 feet, at the junction of the Lehigh and Delaware rivers. It is a railway centre of importance, since it is entered by five lines, the Bangor and Portland, the New Jersey Central, the Delaware, Lackawanna, and Western, the Lehigh and Hudson Rivers, and the Lehigh Valley. It is divided into twelve wards. It is the seat of Lafayette College, a Presbyterian institution which in 1899 had a faculty of 28, and was attended by 309 students; its property was valued at nearly $1,000,000, and its income for the year was $40,315. Population (1880), 11,924; (1890), 14,481; (1900), 25,238, of whom 2135 were foreign-born and 325 negroes. The death-rate in 1900 was 16·7.

**East Orange,** a township of Essex county, New Jersey, U.S.A., on branches of the Delaware, Lackawanna, and Western and the Erie Railways, by which it is connected with New York, 12 miles distant. It is a suburban residential town for New York business men. Population (1880), 8349; (1890), 13,282; (1900), 21,506, of whom 3950 were foreign-born and 1420 negroes.

**Eastport,** a city and port of entry of Washington county, Maine, U.S.A., the most easterly point of the United States, on Moose Island, in Passamaquoddy Bay. It has a good harbour, although the rise and fall of the tide is great, 25 feet, and it is connected in summer with Boston and Portland by daily steamers. It has considerable industry in the canning of so-called sardines. Certain of the neighbouring islands in Passamaquoddy Bay are well-known summer resorts, among which are Campo Bello and Grand Manan, on the Canadian side of the boundary. Population (1880), 4006; (1890), 4908; (1900), 5311, of whom 1554 were foreign-born.

**East Portland,** formerly a city of Multnomah county, Oregon, U.S.A., annexed to Portland in 1891, on the east bank of the Willamette river. Population (1880), 2934; (1890), 10,532.

**East Providence,** a town of Providence county, Rhode Island, U.S.A., on the east side of the Providence river, opposite Providence. Within its area of 12½ square miles are several villages, the largest of which bears the same name as the town. A branch of the New York, New Haven, and Hartford railroad crosses the town. Population (1880), 5056; (1890), 8422; (1900), 12,138, of whom 2067 were foreign-born and 369 negroes.

**East St Louis,** a city of St Clair county, Illinois, U.S.A., in 38° 38′ N. lat. and 90° 10′ W. long., on the east bank of the Mississippi, at an altitude of 418 feet. Its site is in the American Bottom, little above the high-water mark of the river. This bottom stretches a long distance up and down the river, with a breadth of 10 or 12 miles. It is intersected by many sloughs and crescent-shaped lakes, which indicate former courses of the river. East St Louis is one of the great railway centres of the country. Into it enter from the east fourteen lines of railway, which cross to St Louis by the celebrated steel arch bridge, designed and built by J. B. Eads, and by the Merchants' Bridge. It has also extensive dockyards. Population (1880), 9185; (1890), 15,169; (1900), 29,655, of whom 3920 were foreign-born and 1799 negroes.

**Eau Claire,** capital of Eau Claire county, Wisconsin, U.S.A., in 44° 51′ N. lat. and 91° 30′ W. long., at the junction of the Eau Claire and Chippewa rivers, at the head of navigation on the latter, at an altitude of 789 feet. It is on branches of the Chicago, Milwaukee, and St Paul, the Chicago, St Paul, Minneapolis, and Omaha, and the Wisconsin Central Railways. It is an important city in the lumber trade, and has many saw and planing mills. Population (1880), 10,119; (1890), 17,415; (1900), 17,517.

**Ebbw Vale,** an urban district in the Western parliamentary division of Monmouthshire, England, 9 miles west-south-west of Abergavenny by rail. There is a library and scientific institute. The district contains large collieries and important iron and steel works. Area of urban district, 6817 acres. Population (1881), 14,700; (1901), 20,993.

**Ebers, Georg** (1837–1898), German Egyptologist and novelist, was born in Berlin on the 1st of March 1837. He was a posthumous child, and was chiefly educated by his mother. The rupture of a blood-vessel, occasioned by a chill caught in returning lightly clad from a ball in the depth of winter, led him to turn his thoughts seriously to study. At Göttingen he studied jurisprudence, and at Berlin Oriental languages and archæology. By the advice of Brugsch and Lepsius he devoted himself mainly to Egyptology. In 1865 he became *docent* in Egyptian language and antiquities at Jena, and in 1870 he was appointed professor in these subjects at Leipzig. He had made two scientific journeys to Egypt, and his first great work, *Egypt and the Books of Moses*, appeared in 1867–68. Having discovered the celebrated medical papyrus which bears his name, he edited it in 1874, and a translation was published in 1890 by H. Joachim. At an early period of his career Ebers conceived the idea of popularizing Egyptian lore through the medium of historical romances. *An Egyptian Princess* was published in 1864, and obtained great success. Ebers's subsequent experiments in the same style—*Uarda* (1877), *The Sisters* (1880), *Serapis* (1885), *Homo Sum* (1887)—were also well received, and deservedly so, for, although not belonging to a very exalted class of literature, they did much to render the discoveries of Egyptologists common property throughout Europe. When this vein was exhausted Ebers turned to ordinary historical fiction, and many of his novels were translated into English and obtained considerable popularity; but his efforts in this department, though not inferior in talent, lacked the special recommendation of his Egyptian romances. He also wrote the life of his old preceptor Lepsius, and an autobiography. The state of his health led him in 1889 to retire on a pension from his chair at Leipzig, without, however, interrupting his literary activity. He died in August 1898.

**Eberswalde,** till 1877 named NEUSTADT-EBERSWALDE, a town of Prussia, 28 miles north-east of Berlin by rail; on the Finow Canal. The town has, besides the school of forestry, a gymnasium, a higher-grade girls' school, and two schools of domestic economy. Population (1890), 16,114; (1900), 21,654.

**Eccles,** a municipal borough (1892) in the Eccles parliamentary division of Lancashire, England, 4 miles west of Manchester by rail. The Manchester Ship Canal passes the town. The chief additions comprise a town-hall, magistrates' court-house, sewage disposal works, town's yard, electric light works, theatre, two recreation grounds (1892), and several open spaces; three Established churches, one Roman Catholic church; and the Wesleyan, Congregational, and Unitarian bodies possess handsome edifices. Eccles wakes, abolished in 1881, are held on private ground. Silk-throwing and the manufacture of fustians and ginghams are among the industries, and there are also large engine works. Area, 2008 acres. Population (1881), 21,850; (1901), 34,369.

**Ecclesfield,** a township in the Hallamshire parliamentary division of Yorkshire, England, 5 miles north of Sheffield by rail. There are remains of a Benedictine priory. The parish church (about 1470) has been restored. Cutlery and tools are largely manufactured, and there are coal-mines, paper mills, and iron and fire-clay works. Area of township, 10,893 acres. Population (1881), 21,156; (1901), 34,153.

**Ecclesiasticus,** or BEN SIRA (Hebrew Fragments).—That the book called in Latin *Ecclesiasticus*, in Greek Σειράχ, and by Jerome *Jesu filii Sirach liber*, was composed in Hebrew was known to Jerome (*d.* A.D. 420), who testified "Hebraicum repperi." Saadiah Gaon (*fl. circ.* A.D. 930) of the Fayyum in the *Sepher haggalui* refers to Ben Sira's work as written in pointed and accented Hebrew. After this all trace of a Hebrew Ecclesiasticus disappeared until Dr S. Schechter identified a loose leaf from Palestine, and published it in the *Expositor* for July 1896. More leaves were soon discovered at Oxford and at Cambridge, in the British Museum, and at Paris. Probably all these leaves came from the cellar (*gĕnīzah*) of the old synagogue at Cairo. The beginning of the book is still missing, but three colophons are preserved. The most ancient of these was attached to chap. l., before the supplementary chap. li. was added to the original book. It runs: *The Instruction of Understanding and the Proverbs fitly spoken of Simeon son of Jeshua son of Eleazar son of Sira. . . . Happy is the man who meditateth on these; and he that layeth them to heart shall be wise: for the fear of Jehovah is life.* From this colophon (and from the *Sepher haggalui*) we learn that the author's name was *Simeon son of Jeshua* (Jesus), though the LXX and Syriac seem to call him *Jesus*. (The writer of the Greek prologue may be wrong in attributing the book he "found" in Egypt to his ancestor Jesus, and not to Simeon, perhaps his uncle.) This ancient colophon also tells us (in agreement with Jerome) that the title of the book was "Proverbs." In Talmudic and Rabbinic literature it is called simply the *Book of Ben Sira*. G. Bickell, Israel Lévi, and D. S. Margoliouth have argued that the Hebrew is only a retranslation from a Version. Most Hebrew scholars, however, believe that though the text has suffered much, especially by the addition of glosses, the fragments as a whole are a survival from the Hebrew original. The following portions have been published in Hebrew: Chaps. iii. 6–xvi. 26 a; [gap]; xxv. 8–xxvi. 2 (text abbreviated); [gap]; xxx. 11–xxxiii. 3; [gap]; xxxv. 9–xxxviii. 27 a; [gap]; xxxix. 15 b–*ad fin.* These fragments were published by S. Schechter and C. Taylor (Cambridge, 1899); E. N. Adler, *J.Q.R.*, April 1900; S. Schechter (*ibid.*); G. Margoliouth, *J.Q.R.*, October 1899; and by A. E. Cowley and A. Neubauer (Oxford, 1897). In addition to these, Isr. Lévi published (*R.E.J.* tom. xl. No. 79) chaps. xxxvi. 24–xxxviii. 1 from a MS. which shows some variations from the text previously published. At the present time four different MSS. are known, of which the largest (called "B" by Schechter-Taylor) contains (with some gaps) chaps. xxx. 11–*ad fin.* A complete edition in collotype facsimile of all the above-mentioned fragments was published jointly by the two University Presses (Oxford and Cambridge, 1901). The Hebrew contains interpolations, but it also preserves original passages missing from the Versions. One of these is a Psalm of 15 verses found between verses 12 and 13 of chap. li. (This passage is doubtless pre-Maccabean, for it gives honourable mention to the priestly House of Zadok, which fell into disrepute during the Maccabean struggle.) The Hebrew often agrees strikingly with the Syriac; when it agrees with the Greek, it is more often with a cursive MS. (H. and P. No. 248[1]) than with the uncials. The English R.V., following the uncials, often disagrees with the Hebrew. "The language is classical Hebrew," wrote Cowley and Neubauer in 1897, "though the vocabulary has an admixture of late or Aramaic words or expressions" (preface, xiii). But the discovery of further fragments made a qualification of this verdict necessary. In 1899 Dr Schechter wrote, "Strained as [Ben Sira's] efforts were in imitating [the Scriptures], he failed in the end"; a tell-

[1] *Ecclesiasticus* is published from this MS. by the Cambridge University Press, under the editorship of Mr J. H. A. Hart, St John's College.

ing list of Rabbinic expressions which follows justifies this judgment (Schechter and Taylor, pp. 33, 34). Ben Sira's book is an echo of books greater than itself. (W. E. B.)

**Echegaray y Eizaguirre, José** (1833– ——), Spanish mathematician, statesman, and dramatist, was born at Madrid in March 1833, and was educated at the grammar school of Murcia, whence he proceeded to the Escuela de Caminos at the capital. His exemplary diligence and unusual mathematical capacity were soon noticed. In 1853 he passed out at the head of the list of engineers, and, after a brief practical experience at Almería and Granada, was appointed professor of pure and applied mathematics in the school where he had lately been a pupil. His *Problemas de geometría analítica* (1865) and *Teorías modernas de la física unidad de las fuerzas materiales* (1867) are said to be esteemed by competent judges. He became a member of the Society of Political Economy, helped to found *La Revista*, and took a prominent part in propagating Free Trade doctrines in the press and on the platform. He was clearly marked out for office, and when the popular movement of 1868 overthrew the monarchy, he resigned his post for a place in the revolutionary cabinet. Between 1867 and 1874 he acted as Minister of Education and of Finance; upon the restoration of the Bourbon dynasty he withdrew from politics, and won a new reputation as a dramatist. As early as 1867 he wrote *La hija natural*, which was rejected, and remained unknown till 1877, when it appeared with the title of *Para tal culpa tal pena*. Another play, *La última noche*, also written in 1867, was produced in 1875; but in the latter year Echegaray was already accepted as the successful author of *El Libro talonario*, played at the Teatro de Apolo on 18th February 1874, under the transparent pseudonym of Jorge Hayaseca. Later in the same year Echegaray won a popular triumph with *La Esposa del vengador*, in which the good and bad qualities—the clever stagecraft and unbridled extravagance—of his later work are clearly noticeable. From 1874 onwards he has written, with varying success, a prodigious number of plays. Among the most favourable specimens of his talent may be mentioned *En el puño de la espada* (1875); *Ó locura ó santidad* (1877), which has been translated into Swedish and Italian; *En el seno de la muerte* (1879), of which there exists an admirable German version by Fastenrath. *El gran Galeoto* (1881), perhaps the best of Echegaray's plays in conception and execution, has been translated into several languages, and still holds the stage. The humorous proverb, *¿ Piensa mal y acertarás ?* exemplifies the author's limitations, but the attempt is interesting as an instance of ambitious versatility. His susceptibility to new ideas is illustrated in such pieces as *El hijo de Don Juan* (1892) and *El loco Dios* (1900): both of these plainly prove a close reading of Ibsen, and *El loco Dios* more especially might be taken for an unintentional parody of Ibsen's symbolism. Confirmatory signs of a new departure are noticeable in *Mariana* (1892), in *Mancha que limpia* (1895), and in many other productions. Echegaray has succeeded to the literary inheritance of López de Ayala and of Tamayo y Baus; and though he possesses neither the poetic imagination of the first nor the instinctive tact of the second, it is impossible to deny that he has reached a larger audience than either. Not merely in Spain, but in every land where Spanish is spoken, and in cities as remote from Madrid as Munich and Stockholm, he has met with an appreciation incomparably beyond that accorded to any other Spanish dramatist of the 19th century. But it would be more than usually rash to prophesy that this exceptional popularity will endure. There have been signs of a reaction in Spain itself. Echegaray applies his mathematics to the drama: no writer excels him in artful construction, in the arrangement of dramatic scenes, in mere theatrical technique, in the focussing of attention on his chief personages. These are valuable gifts in their way, and it is just to say that Echegaray has a singularly powerful, gloomy imagination, which is momentarily impressive. In the drawing of character, in the invention of felicitous phrase, in the contrivance of verbal music, he is deficient. He alternates between the use of verse and prose; and this hesitancy in choosing a medium of expression is amply justified, for the writer's prose is not more distinguished than his verse. These serious shortcomings may explain the diminution of his vogue in Spain; they will certainly tell against him in the estimate of posterity.

**Echinodermata.**—Since the article on Echinoderms in the 9th edition of the *Encyclopædia Britannica* was published, our knowledge of this phylum of the animal kingdom has greatly increased, and our views on many important points have correspondingly changed. In 1877 the researches of Johannes Müller formed the groundwork of scientific conceptions of the group, and they had thus far been confirmed rather than added to. The distinction of Echinoderms from such radiate animals as jelly-fish and corals (see Cœlentera), by their possession of a body-cavity ("cœlom") distinct from the gut, was fully realized; while their severance from the worms (especially Gephyrea), with which some Echinoderms were long confused, had been necessitated by the recognition in all of a radial symmetry, impressed on the original bilateral symmetry of the larva through the growth of a special division of the cœlom, known as the "hydrocœl," and giving rise to a set of water-bearing canals—the water-vascular or ambulacral system. There was also sufficient comprehension of the differences between the main classes of Echinoderms—the sea-urchins or Echinoidea, the starfish or Asteroidea, the brittle-stars and their allies known as Ophiuroidea, the worm-like Holothurians, the feather-stars and sea-lilies called Crinoidea, with their extinct relatives the sac-like Cystidea, the bud-formed Blastoidea, and the flattened Edrioasteroidea—while within the larger of these classes, such as Echinoidea and Crinoidea, fair working classifications had been established. But the study that should elucidate the fundamental similarities or homologies between the several classes, and should suggest the relations of the Echinodermata to other phyla, had scarcely begun. Indeed, the time was not ripe for such discussions, still less for the tracing of lines of descent and their embodiment in a genealogical classification. Since then exploring expeditions have made known a host of new genera, often exhibiting unfamiliar types of structure.

Among these the abyssal starfish and holothurians described by Sladen and Théel respectively, in the Report of the "*Challenger*" Expedition, are most notable. The sea-urchins, ophiuroids, and crinoids also have yielded many important novelties to A. Agassiz (*Challenger*, *Blake*, and *Albatross* Expeditions), Lyman (*Challenger*), Sladen ("Astrophiura," *Ann. Mag. Nat. Hist.*, 1879), Bell (numerous papers in *Ann. Mag. Nat. Hist.* and in *Proc. Zool. Soc.*), E. Perrier (*Travailleur* and *Talisman*, Cape Horn, and Monaco Expeditions), P. H. Carpenter (*Challenger* Reports), and others. The anatomical researches of these authors, as well as those of Lovén ("On Pourtalesia" and "Echinologica," published by the Swedish Academy of Science), Ludwig (*Morphologische Studien*, Leipzig, 1877–1882), Hamann (*Histologie der Echinodermen*, Jena, 1883–1889), Cuénot ("Études morphologiques," *Arch. Biol.*, 1891, and papers therein referred to), Duncan ("Revision of the Echinoidea," *Journ. Linn. Soc.*, 1890), Prouho ("Sur Dorocidaris," *Arch. Zool. Exper.*, 1888), and many more, need only be mentioned to recall the great advance that has been made. In physiology may be instanced W. B. Carpenter's proof of the nervous nature of the chambered organ and axial cords of crinoids (*Proc. Roy. Soc.*, 1884), the researches of Durham (*Quart. Journ. Micr. Sci.*, 1891) and others into the wandering cells of the body-cavity, and the study of the deposition of the

skeletal substance ("stereom") by Théel (in *Festskrift för Lilljeborg*, 1896). Knowledge of the development has been enormously extended by numerous embryologists, *e.g.*, Ludwig (*op. cit.*), MacBride ("Asterina gibbosa," *Quart. Journ. Micr. Sci.*, 1896), Bury (*Quart. Journ. Micr. Sci.*, 1889, 1895), Seeliger (on "Antedon," *Zool. Jahrb.*, 1893), Goto ("Asterias pallida," *Journ. Coll. Sci. Japan*, 1896), Grave ("Ophiura," *Mem. Johns Hopkins Univ.*, 1899), Théel ("Echinocyamus," *Nov. Act. Soc. Sci. Upsala*, 1892), Semon ("Synapta," *Jena. Zeitschr.*, 1888), and Lovén (*opp. citt.*); and though the theories based thereon may have been fantastic and contradictory, we are now near the time when the results can be co-ordinated and some agreement reached. But the scattered details of comparative anatomy are capable of manifold arrangement, while the palimpsest of individual development is not merely fragmentary, but often has the fragments misplaced. The morphologist may propose classifications, and the embryologist may erect genealogical trees, but all schemes which do not agree with the direct evidence of fossils must be abandoned; and it is this evidence, above all, that gained enormously in volume and in value during the last quarter of the 19th century. The Silurian crinoids and cystids of Sweden have been illustrated in Angelin's *Iconographia Crinoideorum*, 1878; the Palæozoic crinoids and cystids of Bohemia are dealt with in Barrande's *Système Silurien*, 1887 and 1899; P. H. Carpenter published important papers on fossil crinoids in the *Journal* of the Geological Society, on Cystidea in that of the Linnean Society, 1891, and, together with R. Etheridge, jun., compiled the large *Catalogue of Blastoidea in the British Museum*, 1886; O. Jaekel, in addition to valuable studies on crinoids and cystids appearing in the *Zeitschrift* of the German Geological Society, has published the first volume of *Die Stammesgeschichte der Pelmatozoen* (Berlin, 1899), a richly suggestive work; the Mesozoic Echinoderms of France, Switzerland, and Portugal have been made known by P. de Loriol, G. H. Cotteau, J. Lambert, V. Gauthier, and others (see *Paléontologie Française*, *Mem. Soc. Paléontol. de la Suisse*, *Trabalhos Comm. Geol. Portugal*, &c.); a beautiful and interesting Devonian fauna from Bundenbach has been described by Follmann, Jaekel, and especially Stürtz (see *Verhandl. nat. Verein preuss. Rheinlande*, *Palæont. Abhandl.*, and *Palæontographica*); while the multitude of North American palæozoic crinoids has been attacked by Wachsmuth and Springer in the *Proceedings* of the Philadelphia Academy and the *Memoirs* of the Harvard Museum (1897).

The vast mass of material made known by these and many other distinguished writers has to be included in our classification, and that classification itself must be controlled by the story it reveals. Thus it is that a change, characteristic of modern systematic zoology, is affecting the subdivisions of the classes. It is not long since the main lines of division corresponded roughly to gaps in geological history: the orders were Palæocrinoidea and Neocrinoidea, Palechinoidea and Euechinoidea, Palæasteroidea and Euasteroidea, and so forth. Or divisions were based upon certain modifications of structure which, as we now see, affected assemblages of diverse affinity: thus both Blastoidea and Euechinoidea were divided into Regularia and Irregularia; the Holothuroidea into Pneumophora and Apneumona; and Crinoids were discussed under the heads "stalked" and "unstalked." The barriers between these groups may be regarded as horizontal planes cutting across the branches of the ascending tree of life at levels determined chiefly by our ignorance; as knowledge increases, and as the conception of a genealogical classification gains acceptance, they are being replaced by vertical partitions which separate branch from branch. The changes may be appreciated by comparing the systematic synopses in the *Treatise on Zoology*, edited by Ray Lankester, with the classification adopted in the article in *Ency. Brit.*, 9th ed., vol. vii., or in any zoological text-book contemporary therewith. In the present stage of our knowledge these minor divisions are the really important ones. For, whereas to one brilliant suggestion of far-reaching homology another can always be opposed, by the detailed comparison of individual growth-stages in carefully selected series of fossils, and by the minute application to these of the principle that individual history repeats race history, it actually is possible to unfold lines of descent that do not admit of doubt. The gradual linking up of these will manifest the true genealogy of each class, and reconstruct its ancestral forms by proof instead of conjecture. The problem of the interrelations of the classes will thus be reduced to its simplest terms, and even questions as to the nature of the primitive Echinoderm and its affinity to the ancestors of other phyla may become more than exercises for the ingenuity of youth. Work has been and is being done by the laborious methods here alluded to, and though the diversity of opinion as to the broader groupings of classification is still restricted only by the number of writers, we can point to an ever-increasing body of assured knowledge on which all are agreed. Unfortunately such allusion to these disconnected certainties as alone might be introduced here would be too brief for comprehension, and we are forced to select a few of the broader hypotheses for a treatment that may seem dogmatic and prejudiced.

*Calycinal Theory.*—The theory which had most influence on the conceptions of Echinoderms in the two concluding decades of the 19th century was that of Lovén, elaborated by P. H. Carpenter, Sladen, and others. This, which may be called the *calycinal* theory, will be appreciated by comparing the structure of a simple crinoid with that of some other types. A crinoid reduced to its simplest elements consists of three principal portions—(i.) a theca or test enclosing the viscera; (ii.) five arms stretching upwards or outwards from the theca, sometimes single, sometimes branching; (iii.) a stem stretching downwards from the theca and attaching it to the sea-floor (see Fig. 1). That part of the theca

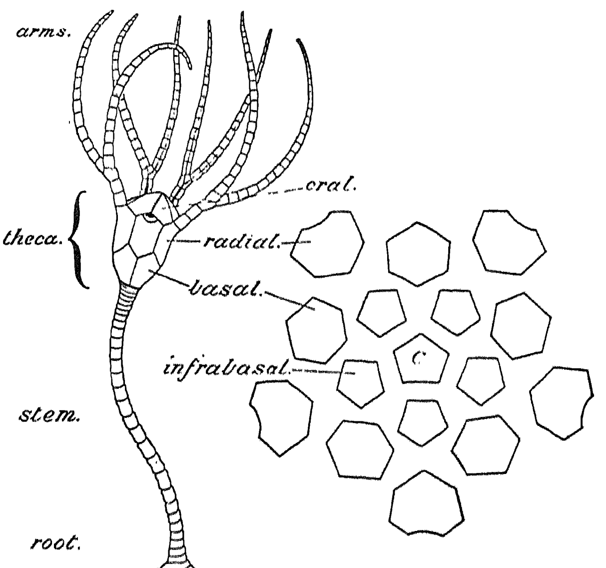

**Fig. 1.—Diagram of a simple form of Crinoid, with five arms, each forking once; the one nearest the observer is removed to expose the tegmen of five orals. This crinoid has only two circlets of plates in the cup, but the cup analysed in the adjoining diagram has in addition infrabasals and a centrale C.**

below the origins of the free arms is called the "dorsal cup"; the ventral part above the origins of the arms, serving as cover to the cup, is known as the "tegmen." All these parts are supported by plates or ossicles of crystalline carbonate of lime. The cup, in its simplest form, consists of two circlets of five plates. Each plate of the upper circlet supports an arm, and is called a "radial"; the plates of the lower circlet, the "basals," rest on the stem and alternate with those of the upper circlet, *i.e.*, are interradial in position. Some crinoids have yet another circlet below these, the constituent plates of which are called "infrabasals," and are situated radially. The tegmen in most primitive forms, as well as in the embryonic stages of the living *Antedon* (Fig. 2), consists of five large triangular plates, alternating with the radials, and called "orals," because they roof over the mouth. In addition to these three or four circlets of plates, two other elements were once supposed essential to the ideal crinoid: the dorso-central and the oro-central. The former term was applied to a flattened plate observed in the embryonic stage of a single genus (*Antedon*) at that end of the stem attached to the sea-floor, and comparable to

the foot of a wine-glass (Fig. 2). In some crinoids which have no trace of a stem (*e.g.*, *Marsupites*) a pentagonal plate is found at the bottom of the cup, where the stem would naturally have arisen ("centrale" in Fig. 1); and since it was believed that the stem always grew by addition of ossicles immediately below the infra-basals, it was inferred that this pentagonal plate was the centro-dorsal in its primitive position, as though the wine-glass had been evolved from a tumbler by pulling the bottom out to form the foot. The oro-central was, it must be admitted, a theoretical conception due to a desire for symmetry, and was not confirmed by anything better than some erroneous observations on certain fossils, which were supposed to show a plate at the oral pole between the five orals; but this plate, so far as it exists at all, is now known to be nothing but an oral shifted in position. The theory was that all the plates just described, and more particularly those of the cup, which were termed "the calycinal system," could be traced, not merely in all crinoids, but in all Echinoderms, whether fixed forms such as cystids and blastoids, or free forms such as ophiuroids and echinoids, even—with the eye of faith—in holothurians. It was admitted that these elements might atrophy, or be displaced, or be otherwise obscured; but their complete and symmetrical disposition was regarded as typical and original. Thus the genera exhibiting it were regarded as primitive, and those orders and classes in which it was least obscured were supposed to approach most nearly the ancestral Echinoderm. Everyone knows that an "apical system," composed of two circlets known as "genitals" or basals and "oculars" or radials, occurs round the aboral pole of echinoids (Fig. 3, A), and that a few

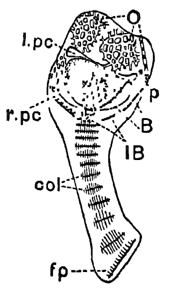

FIG. 2.—An early stage in the development of *Antedon*, showing the foot-plate or "dorso-central" *fp* at the end of the stem *col*. Some of the thecal plates, infrabasals *IB*, basals *B*, and orals *O* are forming around the body-cavities *r.pc* and *l.pc*; *p* is the water-pore. (*After Seeliger*.) × 33 diam.)

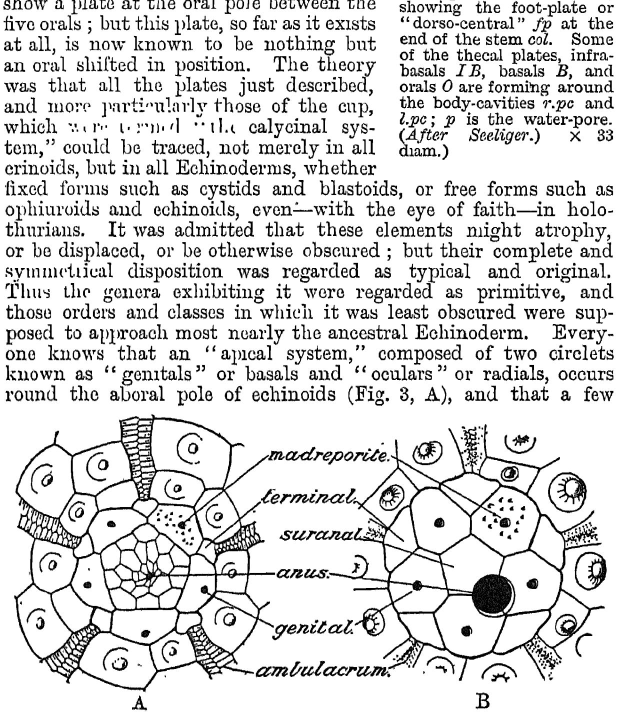

FIG. 3.—Supposed calycinal systems of free-moving Echinoderms. A, regular sea-urchin (*Cidaris*); B, sea-urchin with a sur-anal plate (*Salenia*); C, developing ophiurid (*Amphiura*); D young starfish (*Zoroaster*).

genera (*e.g.*, *Salenia*, Fig. 3, B) possess a sub-central plate (the "sur-anal"), which might be identified with the centro-dorsal. It is also the case that many asterids (Fig. 3, D) and ophiurids (Fig. 3, C) have a similar arrangement of plates on the dorsal (*i.e.*, aboral) surface of the disc. Accepting the homology of these apical systems with the calycinal system, the theory would regard the aboral pole of a sea-urchin or starfish as corresponding in everything, except its relations to the sea-floor, with the aboral pole of a fixed echinoderm.

The theory has been vigorously opposed, notably by Semon (*op. cit.*), who saw in the holothurians a nearer approach to the ancestral form than was furnished by any calyculate echinoderm, and by the Sarasins, who derived the echinoids from the holothurians through forms with flexible tests (Echinothuridæ, which, however, are now known to be specialized in this respect). The support that appeared to be given to the theory by the presence of supposed calycinal plates in the embryo of echinoids and asteroids has been, in the opinion of many, undermined by MacBride (*op. cit.*), who has insisted that in the fixed stage of the developing starfish, *Asterina*, the relations of these plates to the stem are quite different to those which they bear in the developing and adult crinoid. But, however correct the observations and the homologies of MacBride may be, they do not, as Bury (*op. cit.*) has well pointed out, afford sufficient grounds for his inference that the abactinal (*i.e.*, aboral) poles of starfish and crinoids are not comparable with one another, and that all conclusions based on the supposed homology of the dorso-central of echinoids and asteroids with that of crinoids are incorrect. Bury himself, however, has inflicted a severe blow on the theory by his proof that the so-called oculars of Echinoidea, which were supposed to represent the radials, are homologous with the "terminals" (*i.e.*, the plates at the tips of the rays) in Asteroidea and Ophiuroidea, and therefore not homologous with the radially disposed plates often seen around the aboral pole of those animals. For, if these radial constituents of the supposed apical system in an ophiurid have really some other origin, why can we not say the same of the supposed basals? Indeed, Bury is constrained to admit that the view of Semon and others may be correct, and that these so-called calycinal systems may not be heirlooms from a calyculate ancestor, but may have been independently developed in the various classes owing to the action of similar causes. That this view must be correct is urged by students of fossils. Palæontology lends no support to the idea that the dorso-central is a primitive element; it exists in none of the early echinoids, but its origin from the minor plates around the anus is seen in the Saleniidæ. There is no reason to suppose that the central apical plate of certain free-swimming crinoids has any more to do with the distal foot-plate of the larval *Antedon* stem than has the so-called centro-dorsal of *Antedon* itself, which is nothing but the compressed proximal end of the stem. As for the supposed basals of Echinoidea, Asteroidea, and Ophiuroidea, they are scarcely to be distinguished among the ten or more small plates that surround the anus of *Bothriocidaris*, which is the oldest and probably the most ancestral of fossil sea-urchins (Fig. 5). A calycinal system may be quite apparent in the later Ophiuroidea and in a few Asteroidea, but there is no trace of it in the older Palæozoic types, unless we are to transfer the appellation to the terminals. Those plates are perhaps constant throughout sea-urchins and starfish (though it would puzzle any one to detect them in certain Silurian echinoids), and they may be traced in some of the fixed echinoderms; but there is no proof that they represent the radials of a simple crinoid, and there are certainly many cystids in which no such plates existed. Lovén and M. Neumayr adduced the Triassic sea-urchin *Tiarechinus*, in which the apical system forms half of the test, as an argument for the origin of Echinoidea from an ancestor in which the apical system was of great importance; but a genus appearing so late in time, in an isolated sea, under conditions that dwarfed the other echinoid dwellers therein, cannot seriously be thought to elucidate the origin of pre-Silurian Echinoidea, and the recent discovery of an intermediate form suggests that we have here nothing but degenerate descendants of a well-known Palæozoic family (Lepidocentridæ). But to pursue the tale of isolated instances would be wearisome. The calycinal theory is not merely an assertion of certain homologies, a few of which might be disputed without affecting the rest: it governs our whole conception of the echinoderms, because it implies their descent from a calyculate ancestor—not a "crinoid-phantom," that bogey of the Sarasins, but a form with definite plates subject to a quinqueradiate arrangement, with which its internal organs must likewise have been correlated. To this ingenious and plausible theory the revelations of the rocks are more and more believed to be opposed.

*Pentactœa Theory*.—In opposition to the calycinal theory has been the *Pentactœa* theory of Semon. There have always been many zoologists prepared to ascribe an ancestral character to the holothurians. The absence of an apical system of plates; the fact that radial symmetry has not affected the generative organs, as it has in all other recent classes; the well-developed muscles of the body-wall, supposed to be directly inherited from some worm-like ancestor; the presence on the inner walls of the body in the family Synaptidæ of ciliated funnels, which have been rashly compared to the excretory organs (nephridia) of many worms; the outgrowth from the rectum in other genera of cæca (Cuvierian organs and respiratory trees), which recall the anal glands of the Gephyrean worms; the absence of podia (tube-feet) in many genera, and even of the radial water-vessels in Synaptidæ; the absence of that peculiar structure known in other echinoderms by the names "axial organ," "ovoid gland," &c.; the simpler form of the larva—all these features have, for good reason or bad, been

regarded as primitive. Some of the more striking of these features are confined to Synaptidæ; in that family too the absence of the radial water-vessels from the adult is correlated with continuity of the circular muscle-layer, while the gut runs almost straight from the anterior mouth to the posterior anus. Early in the life-history of *Synapta* occurs a stage with five tentacles around the mouth, and into these pass canals from the water-ring, the radial canals to the body-wall making a subsequent, and only temporary, appearance (Fig. 4). Semon called this stage the *Pentactula*, and supposed that, in its early history, the class had passed through a similar stage, which he called the *Pentactæa*, and regarded as the ancestor of all Echinoderms. It has since been proved that the five tentacles with their canals are interradial, so that one can scarcely look on the *Pentactula* as a primitive stage, while the apparent simplicity of the Synaptidæ, at least as compared with other holothurians, is now believed to be the result of regressive changes. The *Pentactæa*, at all events as it sprang from the brain of Semon, must pass to the limbo of mythological ancestors.

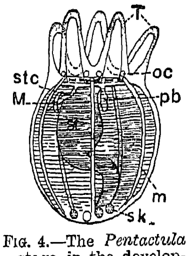

FIG. 4.—The *Pentactula* stage in the development of *Synapta*. *Pelmatozoic Theory*.—The rejection of the calycinal and *Pentactæa* theories need not scatter our conceptions of Echinoderm structure back into the chaos from which they seemed to have emerged. The idea of a calyculate ancestor, though by no means connoting fixation, turned men's minds in the direction of the fixed forms, simply because in them the calyx was best developed. The *Pentactæa* again suggested a search for some primitive type in which quinqueradiate symmetry was exhibited in circumoral appendages, but had not affected the nervous, water-vascular, muscular, or skeletal systems to any great extent, and the generative organs not at all. Study of the earliest larval stages has always led to the conclusion that the Echinoderms must have descended from some freely-moving form with a bilateral symmetry, and, connecting this with the ideas just mentioned, we reach the conception that this supposed bilateral ancestor (or *Dipleurula*) may have become fixed, and may have gradually acquired a radial symmetry in consequence of its sedentary mode of life. The different extent of quinqueradiate symmetry in the different classes would thus depend on the period at which they diverged from the sedentary stock. The tracing of this history, and the explanation of the general characters of Echinoderms and of the differentiating features of the classes in accordance therewith, constitutes the *Pelmatozoic* theory.

The word "Pelmatozoa" literally means "stalked animals," but the name is now used to denote all Cystidea, Blastoidea, Crinoidea, and Edrioasteroidea, as opposed to the other classes, which may be called Eleutherozoa. Many Pelmatozoa have, it is true, no stalk, while some are freely-moving, but all agree in the possession of certain characters obviously connected with a fixed mode of life. Thus, the mouth is central and turned away from the sea-floor; the animal does not seize its food by tentacles, limbs, or jaws, neither does it move in search of it, but a series of ciliated grooves which radiate from the mouth sweep along currents of water, in the eddies of which minute food-particles are caught up and carried down into the gullet; the undigested food is driven out through an anus which is on the upper or oral side of the theca, but as far distant as practicable from the mouth and ciliated grooves. Such characters are found in any primitive, sedentary group. More peculiarly Echinoderm features, in which the Pelmatozoan nature is manifest, are the enclosing of the viscera in a calcified and plated theca, for protection against those enemies from which a fixed animal cannot flee; the development, at the aboral pole of this theca, of a motor nerve-centre giving off branches to the stroma connecting the various plates of the theca and of its brachial, anal, and columnar extensions, and thus co-ordinating the movements of the whole skeleton; the absence of suckers from the podia, which, when present, are respiratory, not locomotor, in function. There are other features of most, if not all, Pelmatozoa that appear to be due to a fixed existence, but those are also found in the Eleutherozoa. The Pelmatozoic theory thus regards the Pelmatozoa as the more ancestral forms, and the Pelmatozoan stage as one that must have been passed through by all Echinoderms during their evolution from the *Dipleurula*. It might be possible to prove the origin of all classes from Pelmatozoa, without thereby explaining the origin of such fundamental features as radial symmetry, the developmental metamorphosis, and the torsion that affects both gut and body-cavities during that process; but the acceptance of a *Dipleurula* as the common ancestor necessitates an explanation of these features. Such explanation is an integral part of the Pelmatozoic theory, but is provided by no other.

The evidence for the Pelmatozoic theory is supplied by palæontology, embryology, the comparative anatomy of the classes, and a consideration of other phyla. Palæontology, so far as it goes, is a sure guide, but some of the oldest fossiliferous rocks yield remains of distinctly differentiated crinoids, asteroids, and echinoids, so that the problem is not solved merely by collecting fossils. Two lines of argument appear fruitful. First, a comparison of the relative numbers of the representatives of the various classes at different epochs; according to this they may be placed in the following order, with the oldest first: Cystidea, Crinoidea, Blastoidea, Asteroidea, Ophiuroidea, Echinoidea. As for Holothuroidea, the fossil evidence allows us to say no more than that the class existed in early Carboniferous times, if not before. The second method is to work out by slow and sure steps the lines of descent of the different families, orders, and classes, and so either to arrive at the ancestral form of each class, or to plot out the curve of evolution, which may then legitimately be projected into "the dark backward and abysm of time." In this way the many highly modified orders of Cystidea may be traced back to a simple, many-plated ancestor with little or no radiate symmetry (see below). All the complicated structures of Blastoidea are evolved from a fairly simple type, which in its turn is linked on to one of the cystid orders. That the crinoids are all deducible from some such simple form as that above described under the head "calycinal theory," is now generally admitted. Although, in the extreme correlation of the radial food-grooves, nerves, water-vessels, and so forth, with a radiate symmetry of the theca, such a type differs from the Cystidea, while in the possession of jointed processes from the radial plates, bearing the grooves and the various body-systems outwards from the theca, it differs from all other Echinoderms, nevertheless ancient forms are known which, if they are not themselves the actual links, suggest how the crinoid type may have been evolved from some of the more regular cystids. The fourth class of Pelmatozoa—the Edrioasteroidea—differs from the others in the structure of its ambulacra. As in all Pelmatozoa, these seem to have borne ciliated food-grooves protected by movable covering-plates (Fig. 11). Beneath each food-groove was a radial water-vessel and probably a nerve and blood-vessel, all which structures passed either between certain regularly arranged thecal plates, or along a furrow floored by those plates, which were then in two alternating series. The important and distinctive feature is the presence of pores between the flooring-plates, on either side of the groove; and these, we cannot doubt, served for the passage of podia. Thus in a highly developed edrioasteroid, such as *Edrioaster* itself (Fig. 11), there was a true ambulacrum, apparently constructed like that of a starfish, but differing in the possession of a ciliated food-groove protected by covering-plates. The simpler forms of Edrioasteroidea, with their more sac-like body and undifferentiated plates, may well have been derived from early Cystidea of yet simpler structure, and there seems no reason to follow Jaekel in regarding the class as itself the more primitive. Turning to fossil Asteroidea, we find the earlier ophiurids scarcely distinguishable from the asterids, while in the alternation of the ambulacrals, which undoubtedly correspond to the flooring-plates of *Edrioaster*, both groups approach the Pelmatozoan type. These facts have been expressed by Stürtz in his names Encrinasteriæ and Ophio-encrinasteriæ. There is no difficulty in deducing the highly differentiated asterids and ophiurids of a later day from these simpler types. The evolution of the modern Echinoidea from their Palæozoic ancestors is also well understood, but in this case the ancestral form to which the palæontologist is led does not at first sight present many resemblances to the Pelmatozoa. It is, however, characterized by simplicity of structure, and a short description of it will serve to clear the problem from unnecessary difficulties. *Bothriocidaris* (Fig. 5), a small echinoid from the

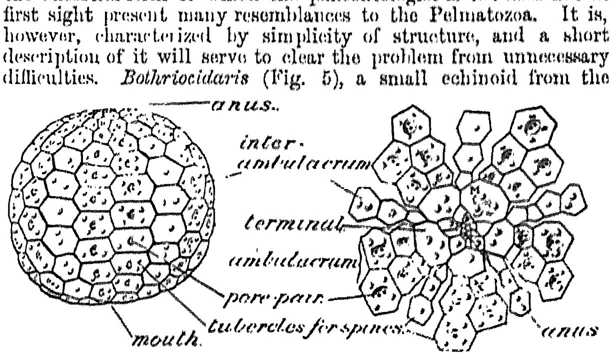

FIG. 5.—*Bothriocidaris globulus*. A, from the side; B, the plates around the aboral pole. (*After Jaekel.*) The short spines which were attached to the tubercles are not drawn.

Ordovician rocks of Esthonia, is in essential structure just the form demanded by comparative palæontology to make a starting-point. It is spheroidal, with the mouth and anus at opposite

poles; there are five ambulacra, and the ambulacral plates are large, simple, and alternating, each being pierced by two podial pores which lie in a small oval depression; the ambulacrals next the mouth form a closed ring of ten plates; the interambulacrals lie in single columns between the ambulacra, and are separated from the mouth-area by the proximal ambulacrals just mentioned, and sometimes by the second set of ambulacrals also; the ambulacra end in the five oculars or terminals, which meet in a ring around the anal area and have no podial pores, but one of them serves as a madreporite; within this ring is a star-shaped area filled with minute irregular plates, none of which can safely be selected as the homologues of the so-called basals or genitals of later forms; within the ring of ambulacrals around the mouth are five somewhat pointed plates, which Jaekel regards as teeth, but which can scarcely be homologous with the interradially placed teeth of later echinoids, since they are radial in position; small spines are present, especially around the podial pores. The position of the pores near the centre of the ambulacrals in *Bothriocidaris* need not be regarded as primitive, since other early Palæozoic genera, not to mention the young of living forms, show that the podia originally passed out between the plates, and were only gradually surrounded by their substance; thus the original structure of the echinoid ambulacra differed from that of the early asteroid in the position of the radial vessels and nerves, which here lie beneath the plates instead of outside them. To this point we shall recur; palæontology, though it suggests a clue, does not furnish an actual link either between echinoidea and asteroidea, or between those classes and Pelmatozoa.

The argument from embryology leads farther back. First, as already mentioned, it outlines the general features of the *Dipleurula*; secondly, it indicates the way in which this free-moving form became fixed, and how its internal organs were modified in consequence; but when we seek, thirdly, for light on the relations of the classes, we find the features of the adult coming in so rapidly that such intermediate stages as may have existed are either squeezed out or profoundly modified. The difficulty of rearing the larvæ in an aquarium towards the close of the metamorphosis may account for the slight information available concerning the stages that immediately follow the embryonic. Another difficulty is due to the fact that the types studied, and especially the crinoid *Antedon*, are highly specialized, so that some of the embryonic features are not really primitive as regards the class, but only as regards that particular genus. Thus inferences from embryonic development need to be checked by palæontology, and supplemented by comparison of the anatomy of other living genera.

Minute anatomical research has also aided to establish the Pelmatozoic theory by the gradual recognition in other classes of features formerly supposed to be confined to Pelmatozoa. Thus the elements of the Pelmatozoan ventral groove are now detected in so different a structure as the echinoid ambulacrum, while an aboral nervous system, the diminished representative of that in crinoids, has been traced in all Eleutherozoa except Holothurians. The broader theories of modern zoology might seem to have little bearing on the Echinoderma, for it is not long since the study of these animals was compared to a landlocked sea undisturbed by such storms as rage around the origin of the Vertebrata. This, however, is no more the case. The conception of the *Dipleurula* derives its chief weight from the fact that it is comparable to the early larval forms of other primitive cœlomate animals, such as *Balanoglossus*, *Phoronis*, Chætognatha, Brachiopoda, and Bryozoa. So too the explanation of radial symmetry and torsion of organs as due to a Pelmatozoic mode of life finds confirmation in many other phyla. Instead of discussing all these questions separately, with the details necessary for an adequate presentation of the argument, we shall now sketch the history of the Echinoderms in accordance with the Pelmatozoic theory. Such a sketch must pass lightly over debatable ground, and must consist largely of suggestions still in need of confirmation; but if it serves as a frame into which more precise and more detailed statements may be fitted as they come to the ken of the reader, its object will be attained.

*Evolution of the Echinoderms.*—It is reasonable to suppose that the Cœlomata—animals in which the body-cavity is divided into a gut passing from mouth to anus and a hollow (cœlom) surrounding it—were derived from the simpler Cœlentera, in which the primitive body-cavity (archenteron) is not so divided, and has only one aperture serving as both mouth and anus. We may, with Sedgwick, suppose the cœlom to have originated by the enlargement and separation of pouches that pressed outwards from the archenteron into the thickened body-wall (such structures as the genital pouches of some Cœlentera, not yet shut off from the rest of the cavity), and they would probably have been four in number and radially disposed about the central cavity. The evolution of this cavity into a gut is foreshadowed in some Cœlentera by the elliptical shape of the aperture and by the development at its ends of a ciliated channel along which food is swept; we have only to suppose the approximation of the sides of the ellipse and their eventual fusion, to complete the transformation of the radially symmetrical Cœlenterate into a bilaterally symmetrical Cœlomate with mouth and anus at opposite ends of the long axis. We further suppose that of the four cœlomic pouches one was in front of the mouth, one behind the anus, and one on each side. Such an animal, if it ever existed, probably lived near the surface of the sea, and even here it may have changed its medusoid mode of locomotion for one in the direction of its mouth. Thus the bilateral symmetry would have been accentuated, and the organism shaped more definitely into three segments, namely, (1) a preoral segment or lobe, containing the anterior cœlomic cavity; (2) a middle segment, containing the gut, and the two middle cœlomic cavities; (3) a posterior segment, containing the posterior cœlomic cavity, which, however, owing to the backward prolongation of the anus, became divided into two—a right and left posterior cœlom. Each of these cavities presumably excreted waste products to the exterior by a pore. There was probably a nervous area, with a tuft of cilia, at the anterior end; while, at all events in forms that remained pelagic, the ciliated nervous tracts of the rest of the body may be supposed to have become arranged in bands around the body-segments. Such a form as this is roughly represented to-day by the *Actinotrocha* larva of *Phoronis*, the importance of which has been brought out by Masterman. But only slight modifications are required to produce the *Tornaria* larva of the Enteropneusta and other larvæ, including the special type that is inferred from the *Dipleurula* larval stages of recent forms to have characterized the ancestor of the Echinoderms. We cannot enter here into all the details of comparison between these larval forms; amid much that is hypothetical a few homologies are widely accepted, and the preceding account will show the kind of relation that the Echinoderms bear to other animals, including what are now usually regarded as the ancestors of the Chordata (to which back-boned animals belong), as well as the nature of the evidence that their study has been, or may be, made to yield. How the hypothetical *Dipleurula* became an Echinoderm, and how the primitive Echinoderms diverged in structure so as to form the various classes, are questions to which an answer is attempted in the following paragraphs:—

Confining our attention to that form of *Dipleurula* (Fig. 6) which, it is supposed, gave rise to the Echinoderma, we infer

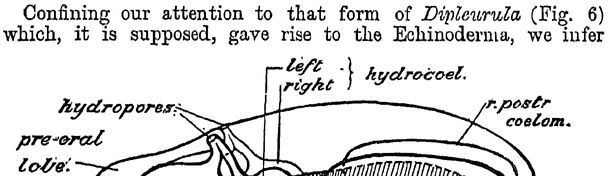

FIG. 6.—Diagrammatic reconstruction of *Dipleurula*. The creature is represented crawling on the sea-floor, but it may equally well have been a floating animal. The ciliated bands are not drawn.

from embryological data that its special features were as follow:—The anterior cœlomic cavity was wholly or partially divided, and from each half a duct led to the exterior, opening at a pore near the middle line of the back. The middle cavities were smaller, and the ducts from them came to unite with those from the anterior cavities, and no longer opened directly to the exterior; whether these cavities were already specialized as water-sacs cannot be asserted, but they certainly had become so at a slightly later stage. The posterior cavities were the largest, but what had become of their original opening to the exterior

is uncertain. The genital products were derived from the lining of the cœlomic cavities, but it would not be safe to say that any particular region was as yet specialized for generation. The epithelium of the outer surface was probably ciliated, and a portion of it in the preoral lobe differentiated as a sense-organ, with longer cilia and underlying nerve-centre, from which two nerves ran back below the ventral surface. Into the space between the walls of the cœlom and the outer body-wall, originally filled with jelly, definite cells now wandered, chiefly derived from the cœlomic walls. Some of these cells produced muscles and connective tissue; others absorbed and removed waste products, iron salts, calcium carbonate, and the like, and so were ready to be utilized for the deposition of pigment or of skeletal substance. In some of these respects the *Dipleurula* may have diverged from the ancestor of Enteropneusta and of other animals, but it could not as yet have been recognized as echinodermal by a zoologist, for it presented none of the structural peculiarities of the modern adult echinoderm.

Now ensued the great event that originated the phylum—the discovery of the sea-floor. This being apprehended by the sensory anterior end, it was by that end that the *Dipleurula* attached itself; not, however, by the pole, since that would have interfered at once with the sensory organ, but a little to one side, the right side being the one chosen for a reason we cannot now fathom; it may be that fixation was facilitated by the presence of the pore on that side, and by the utilization of the excretion from it as a cement. The first result was that which is always seen to follow in such cases—the passage of the mouth towards the upper surface (Fig. 7). As it passed up along the left side, the gut caught hold of the left water-sac and pulled it upwards, curving it in the process; this being attached to the left duct from the anterior body-cavity, this structure with its water-pore was also pulled up, and

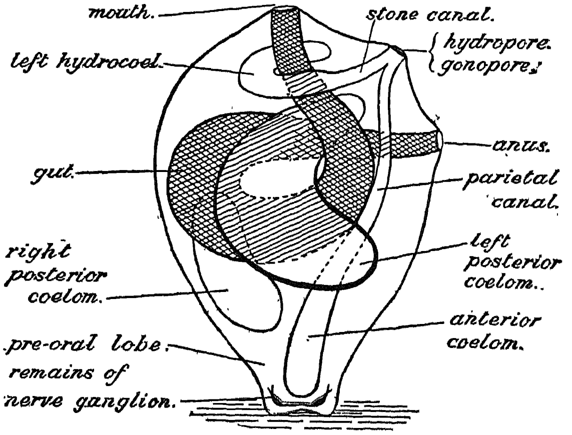

Fig. 7.—Diagrammatic reconstruction of primitive Pelmatozoön, seen from the side. The plates of the test are not drawn; their probable appearance may be gathered from Fig. 8.

the pore came to lie between mouth and anus. The forward portion of the anterior cœlom shared in the constriction and elongation of the preoral lobe; but its hinder portion was dragged up along with the water-pore and formed a canal lying along the outer wall (the parietal canal). As the gut coiled, it pressed inwards the middle of the left posterior cœlom of the *Dipleurula*, and drew the whole towards the mouth, while the corresponding cavity on the right was pressed down by the stomach towards the fixed end of the animal and became involved in the elongation of that region. These changes, which may still be traced in the development of *Antedon*, resulted in the primitive Pelmatozoön (Fig. 7), represented in the rocks by such a genus as *Aristocystis* (Fig. 8). The pear-shaped body is encased in a theca formed by a number of polygonal plates, and is attached by its narrow end. On the broad upper surface are four openings, that nearest the centre being the mouth, which

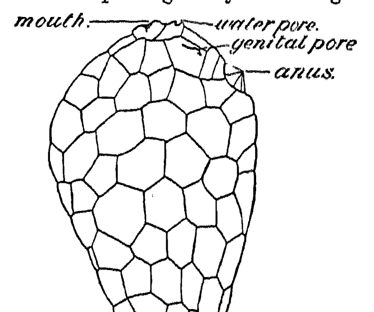

Fig. 8.—*Aristocystis bohemicus*; side-view of the theca. The internal structure may be gathered from Fig. 7. (×⅔ diam.)

is slit-like, and that nearest the periphery being the anus. The two other openings are minute, and placed between those two; one close to the mouth is almost certainly the water-pore, while that nearer the anus is regarded as a genital aperture. Which of the cœlomic cavities this last is connected with is uncertain, for there is considerable doubt as to the origin of the genital glands in the embryonic development of recent echinoderms. It seems clear, however, that there was but a single duct and a single bunch of reproductive cells, as in the holothurians, though perhaps bifurcate, as in some of those animals. The line between mouth and anus, along which these openings are situate, corresponds with the plane of union between the two horns of the curved left posterior cœlom, the united walls of which form the "dorsal mesentery." Since this must have, on our theory, enclosed the parietal canal from the anterior cœlom, it is possible that the genital products were developed from the lining cells of that cavity, and that the genital pore was nothing but its original pore not yet united with that from the water-sac. The concrescence of these pores can be traced in other cystids; but as the genital organs became affected by radial symmetry the original function of the duct was lost, and the reproductive elements escaped to the exterior in another way. *Aristocystis* may have had ciliated food-grooves leading to its mouth, but these have left no traces on the structure of the test. Traces, however, are perceptible in genera believed to be descended from such a simple type, and the majority may be grouped under two heads. One group includes those in which the grooves wander outwards from the mouth over the thecal plates, which gradually become arranged regularly on either side of the grooves, while further extensions ascend from the grooves on small jointed processes called "brachioles" (Fig. 9). In the other group the grooves do not tend so much to stretch over the theca as to be raised away from it on relatively larger brachioles, arising close around the mouth (Fig. 10).

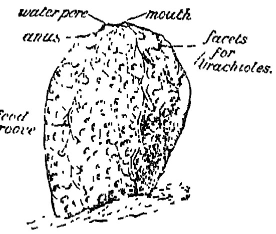

Fig. 9.—*Fungocystis rarissima*, one of the Diploporita, in which the thecal plates bordering the food-grooves are not yet regularly arranged. The brachioles are not drawn.

These two types are, in the main, correlated with two gradual differentiations in the minute structure of the thecal plates. Originally the calcareous substance of the plates (stereom) was pierced by irregular canals, more or less vertical, and containing strands of the soft tissue (stroma) that deposited the stereom, as well as spaces filled with fluid. In the former group (Fig. 9) these canals became connected in pairs (diplopores) still perpendicular to the surface, and this structure, combined with that of the grooves, characterizes the order — Diploporita. In the latter group (Fig. 10) the canals, that is to say, the stroma-strands, came to lie parallel to the surface and to cross the sutures between the plates, which were thus more flexibly and more strongly united; since the canals crossing each suture naturally occupy a rhombic area, the order is called Rhombifera. At first the grooves were three, one proceeding from each end of the mouth-slit, and the third in a direction opposed to the anus; with reference to the Pelmatozoan structure, the anal side may be termed posterior, and this groove anterior. Eventually each lateral groove forked, so that there were five grooves. These gradually impressed themselves on the theca and influenced the arrangement of the internal organs: it is fairly safe to assume that nerves, blood-vessels, and branches from the water-sac stretched

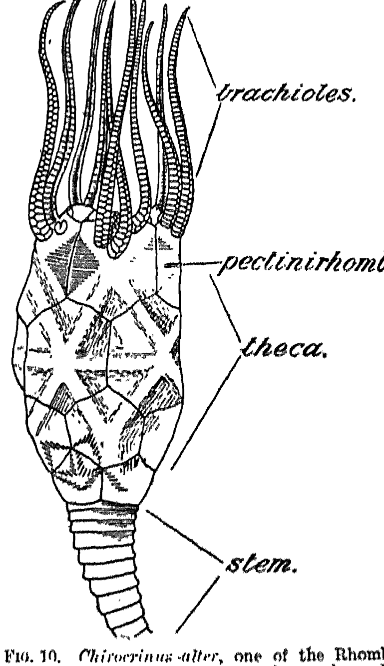

Fig. 10. *Chirocrinus alter*, one of the Rhombifera, showing the reduced number and regular arrangement of the thecal plates, and the concentration of the brachioles. (*Adapted from Jaekel.*)

out along with these grooves, each system starting from a ring around the gullet. At last a quinqueradiate symmetry influenced the plates of the theca, partly through the development of a plate at the end of each groove (terminal), partly through plates at the aboral pole of the theca (basals and infrabasals) arising in response to mechanical pressure, but soon intimately connected with the cords of an aboral nervous system. Before the latter plates arose, the stem had developed by the elongation and constriction of the fixed end of the theca, the gradual regularization of the plates involved, and their coalescence into rings. The crinoid type was differentiated by the extension of the food-grooves and associated organs along radial outgrowths from the theca itself. These constituted the arms (brachia), and five definite radial plates of the theca were specialized for their support. These radials may be homologous with the terminals already mentioned, but this is neither necessary nor certain. In this development of brachial extensions of the theca the genital organs were involved, and their ripe products formed at the ends of the brachia or in the branches therefrom. The remains of the original genital gland within the theca became the "axial organ" surrounded by the "axial sinus" derived from the anterior cœlom, and this again by structures derived from the right posterior cœlom, which, as explained above, had been depressed to the aboral pole. These last structures formed a nervous sheath around the axial sinus with its blood-vessels, and became divided into five lobes correlated with the five basals (the "chambered organ") and forming the aboral nerve-centre. Before these changes were complete the Holothurioidea must have diverged, by the assumption of a crawling existence. Thus in them the mouth and anus reverted to opposite poles, and only the torsion of the gut and cœlom, and the radial extensions of the nervous, water-vascular, and blood-vascular systems, testified to their Pelmatozoan ancestry. The ciliated grooves, no longer needed for the collection of food, closed over, and are still traceable as ciliated canals overlying the radial nerves. At the same time the thecal plates degenerated into spicules. The Edrioasteroidea followed a different line to that of the cystids above mentioned and their descendants. The theca became sessile, and in its later developments much flattened (Fig. 11). Mouth, water-pore, and

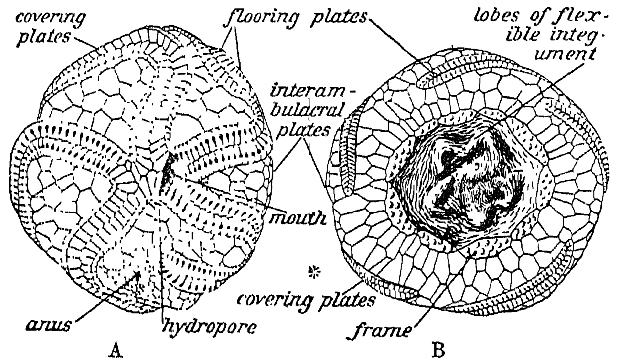

FIG. 11.—*Edrioaster.* A, upper or oral surface of *E. Bigsbyi*, with the covering-plates on the anterior and left posterior food-grooves, but removed from the others, which show only the flooring-plates, between which are pores; B, under surface of *E. Buchianus*, with covering-plates on right posterior and right anterior food-grooves (left hand in the drawing). The ✻ denotes the position of the anal interradius.

anus remained as in *Aristocystis*, but the five ciliated grooves radiated from the mouth between the thecal plates rather than over them, and were, as usual, protected by covering-plates. The important feature was the extension of radial canals from the water-sac along these grooves, with branches passing between the flooring-plates of the grooves (Fig. 12, A). The resemblance of the flooring-plates to the ambulacral ossicles of a starfish is so exact that one can explain it only by supposing similar relations of the water-canals and their branches (podia). On the thinly-plated under surface of well-preserved specimens of *Edrioaster* are seen five interradial swellings (Fig. 11, B). These are likely to have been produced by the ripe genital glands, which may have extruded their products directly through the membranous integument of the under side. No other way out for them is apparent, and it is clear that *Edrioaster* was not permanently and solidly fixed to the sea-floor.

Now comes a great change, unfortunately difficult to follow whether in the fossils or in the modern embryos. We suppose some such form as *Edrioaster*, which appears to have lived near the shore, to have been repeatedly overturned by waves. Those that were able to accommodate themselves to this topsy-turvy existence, by taking food in directly through the mouth, survived, and their podia gradually specialized as sucking feet. Such a form as this, when once its covering-plates had atrophied, would be a starfish without more ado (Fig. 12, B); but the sea-urchins present a more difficult problem. We may suppose that the radial water-canals sank beneath the flooring-plates of the grooves, and that the covering-plates disappeared, in which case the plates that in the echinoid are pierced by podia would be homologous with the ambulacral ossicles of an asteroid and the flooring-plates of *Edrioaster*. Or we may suppose the canals and other organs to have remained as they were, the covering-plates to have closed permanently over them, merely leaving slits for the podia between them, and the flooring-plates to have disappeared. In either case we have to admit a closure of the integument over the ciliated groove (Fig. 12, D, *e*) just as in holothurians, since this is necessitated by

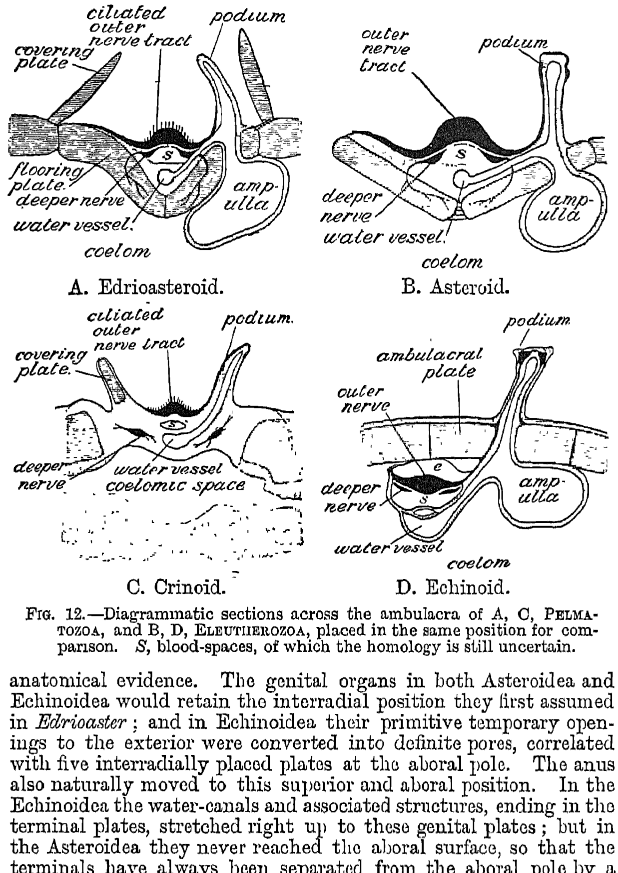

FIG. 12.—Diagrammatic sections across the ambulacra of A, C, PELMATOZOA, and B, D, ELEUTHEROZOA, placed in the same position for comparison. *S*, blood-spaces, of which the homology is still uncertain.

anatomical evidence. The genital organs in both Asteroidea and Echinoidea would retain the interradial position they first assumed in *Edrioaster*; and in Echinoidea their primitive temporary openings to the exterior were converted into definite pores, correlated with five interradially placed plates at the aboral pole. The anus also naturally moved to this superior and aboral position. In the Echinoidea the water-canals and associated structures, ending in the terminal plates, stretched right up to these genital plates; but in the Asteroidea they never reached the aboral surface, so that the terminals have always been separated from the aboral pole by a number of plates.

*Analysis of Echinoderm Characters.*—To follow the further evolution of the several classes would require a series of independent articles; reference must perforce be made to works (*vide infra*) in which this has recently been attempted. Regarding the Echinoderms as a whole in the light of the foregoing account, we may give the following analytic summary of the characters that distinguish them from other cœlomate animals:—

They live in salt or brackish water; a primitive bilateral symmetry is still manifest in the right and left divisions of the cœlom; the middle cœlomic cavities are primitively transformed into two hydrocœls communicating with the exterior indirectly through a duct or ducts of the anterior cœlom; stereom, composed of crystalline carbonate of lime is, with few exceptions, deposited by special amœbocytes in the meshes of a mesodermal stroma, chiefly in the integument; reproductive cells are derived from the endothelium, apparently of the anterior cœlom; total segmentation of the ovum produces a cœloblastula and gastrula by invagination; mesenchyme is formed in the segmentation cavity by migration of cells, chiefly from the hypoblast. Known Echinoderms show the following features, imagined to be due to an ancestral pelmatozoic stage:—Increase in the cœlomic cavities of the left side, and atrophy of those on the right; the dextral coil of the gut, recognizable in all classes, though often obscured; an incomplete secondary bilateralism about the plane including the main axis and the water-pore or its successor, the madreporite, often obscured by one or other of various tertiary bilateralisms; the development of the hydrocœl into a circumoral, arcuate or ring canal; development through a free-swimming, bilaterally symmetrical, ciliated larva, of which in

many cases only a portion is transformed into the adult Echinoderm (where care of the brood has secondarily arisen, this larva is not developed). All living, and most extinct, Echinoderms show the following features, almost certainly due to an ancestral Pelmatozoic stage:—An incomplete radial symmetry, of which five is usually the dominant number, is superimposed on the secondary bilateralism, owing to the outgrowth from the mouth region of one unpaired and two paired ciliated grooves; these have a floor of nervous epithelium, and are accompanied by subjacent radial canals from the water-ring, giving off lateral podia and thus forming ambulacra, and by a perihæmal system of canals apparently growing out from cœlomic cavities. All living Echinoderms have a lacunar, hæmal system of diverse origin; this, the ambulacral system, and the cœlomic cavities, contain a fluid holding albumen in solution and carrying numerous amœbocytes, which are developed in special lymph-glands and are capable of wandering through all tissues. The Echinoderms may be divided into seven classes, whose probable relations are thus indicated:—

PELMATOZOA { Cystidea, Blastoidea, Crinoidea }

Cystidea —— Edrioasteroidea

ELEUTHEROZOA { Holothurioidea, Asteroidea (and Ophiuroidea), Echinoidea }

(F. A. B.)

**Echiuroidea.**—The Echiuroidea form a small group of marine animals which show in their larval life-history a certain degree of segmentation, and are therefore grouped by some authorities as Annelids. Formerly, together with the Sipunculoidea and Priapuloidea, they made up the class Gephyrea, but on the ground that they retain in the adult a large preoral lobe (the proboscis), that they have anal vesicles, that their anus is terminal, that setæ are found, and finally that they are segmented in the larval stage, they have been removed from the group, which by the proposed further separation of the Priapuloidea on account of their unique renal and reproductive organs, has practically ceased to exist.

Echiuroids are animals of moderate size, varying roughly from one to six or seven centimetres in length, exclusive of the proboscis. This organ is capable of very considerable extension, and may attain a length in *Bonellia viridis* of about a metre and a half (Fig. 1). It is grooved ventrally and ciliated. At its attachment to the body the groove sinks into the mouth. In *Bonellia* the proboscis is forked at its free end, but in the other genera it is short and unforked. The body is somewhat sausage-shaped, with the anus at the posterior extremity, surrounded in *Echiurus* by a single or double ring of setæ. The skin is usually wrinkled, and in *B. viridis*, *Thalassema lankesteri*, *Th. baronii*, *Hamingia arctica*, and in the larva of many species, is of a lively green colour. A pair of curved bristles, formed in true setal sacs as in Chætopoda, project from the body a short distance behind the mouth, and are moved by special muscles; they are of use in helping the animal to move

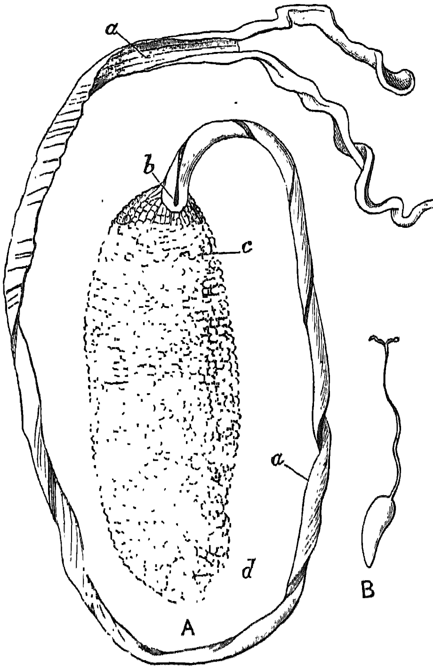

FIG. 1.—A, *Bonellia viridis*, Rol., ♀; B, *B. fuliginosa*. Both natural size. *a*, grooved proboscis; *b*, mouth; *c*, ventral hooks; *d*, anus.

slowly about, and they take a large share in the burrowing movements (C. B. Wilson, *Biol. Bull.*, 1900), for some species tunnel in the mud and sand and form more or less permanent burrows, the walls of which are strengthened by mucus secreted from the skin. The openings of the burrows become silted up, leaving, however, a small aperture through which the proboscis is extruded. This organ carefully searches the neighbourhood for particles of food. When these are found the grooved proboscis folds its walls inwards, and the cilia pass the particles down the tube thus formed to the mouth. Echiuroids also move by extending the proboscis, which takes hold of some fixed object, and then contracting, draws the body forwards. Recently it has been shown that *Echiurus* swims freely at night-time, using for locomotion both the proboscis and the contraction of the muscles of its body-wall. The motion is described as "gyratory," and the anterior end is always carried foremost. Those species which do not burrow usually conceal themselves in crevices of the rocks or under stones, or at times in empty Mollusc or Echinid shells. They are occasionally used by fishermen as bait.

*Anatomy* (Fig. 2).—A thin cuticle covers the epidermis, which contains mucus-secreting glands. Beneath the epidermis is a layer of circular muscles, then a layer of longitudinal, and finally in some cases a layer of oblique muscle-fibres. The inner face of this muscular skin is lined by a layer of epithelium. The cœlomic body-cavity is spacious. It does not extend into the proboscis, which is a solid organ traversed by the nervous and vascular rings, but otherwise largely built up of muscle-fibres and connective-tissue. Many sense-cells lie in the epidermis. The ciliated ventral groove of the proboscis leads at its base into the simple mouth, which gives access to the thin-walled alimentary canal. This is longer than the body, and to tuck it away it is looped from side to side. The loops are supported by strands of connective-tissue, which in some species are united so as to form a dorsal mesentery, whilst traces of a ventral mesentery are met with anteriorly and posteriorly

(H. L. Jameson, *Zool. Jahrb. Anat.*, 1899). The alimentary canal is divisible into fore-gut, mid-gut, and hind-gut, and the first named can be further divided into pharynx, œsophagus, gizzard, and crop, mainly on histological grounds. The mid-gut is characterized by the presence of a ciliated groove, from which arises the collateral intestine or siphon, a second tube which rejoins the alimentary canal lower down. Similar collateral intestines are familiar in the Echinids and certain Polychæts (Capitellidæ). The rectum receives the openings of a pair of very characteristic organs, the anal vesicles. Each consists of a branching tube, the tips of whose twigs terminate in minute ciliated funnels. The anal vesicles are thought to be excretory; whether this be so or not, they undoubtedly have some

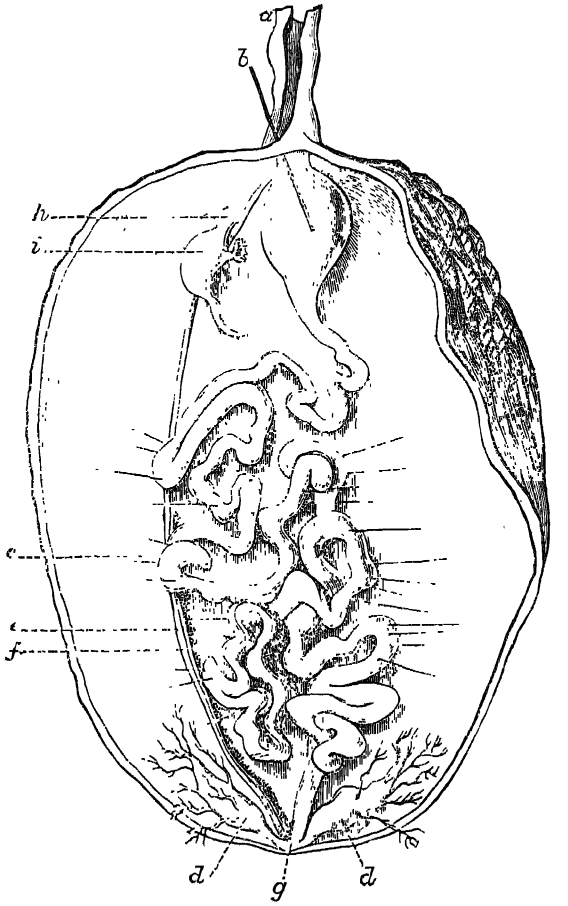

FIG. 2.—Female *Bonellia viridis*, Rol. Opened along the left side. × 2. *a*, proboscis cut short; *b*, bristle passing through the mouth into the pharynx; *c*, coiled intestine; *d*, anal tufts or vesicles; *e*, ventral nerve cord; *f*, ovary borne on ventral vessel running parallel with *e*; *g*, position of anus; *h*, position of external opening of nephridium; *i*, nephridium—the line points towards, but does not reach, the internal opening.

influence on the amount of fluid found in the cœlom. The cœlomic fluid contains as a rule both amœboid and rounded corpuscles, and, when ripe, the products of the gonads. A closed system of vessels, usually called the vascular system, is present. There are, however, no capillaries connected with this, and it is confined to certain portions of the body. It can possess few of the functions usually associated with a vascular system, and its main use is probably to assist in the expansion of the proboscis. The system consists of the following parts:—A dorsal vessel applied to the alimentary canal is continued anteriorly into a median vessel, which traverses the proboscis to its tip. Here the vessel splits, and each half returns along the lateral edge of the proboscis; they reunite around the œsophagus and form a single ventral vessel, which lies above the ventral nerve-cord. The ventral vessel, which ends solidly behind, sends off a branch which forms a ring around the intestine and opens into the posterior extremity of the dorsal vessel. In *Echiurus* and *Thalassema* the same vessel forms a ring round a stout muscle, which connects the bases of the two ventral setæ before passing to surround the intestine. Amœboid corpuscles float in the fluid contents. The nephridia vary in number from a single one in *Bonellia* to three pairs in many species of *Thalassema*. Their external openings are ventral, and on the same level as the ciliated funnel-shaped nephrostomes. The posterior wall of the organ is produced into a long blind sac, which is lined by secretory cells. The nervous system is a single ventral cord, which starts from a circum-œsophageal ring. This ring is involved in the growth of the proboscis, and is drawn out with it. Thus there is a lateral nerve near each edge of the proboscis which unites with its fellow dorsally above the œsophagus at the tip of the proboscis, and ventrally beneath the œsophagus, where they fuse to form the ventral nerve-cord. There are no specialized ganglia, but ganglion-cells are scattered uniformly along the nerve-cords. The ventral cord gives off rings, which run in the skin at regular intervals. The reproductive cells are modified cœlomic cells, which lie on the ventral vessel. They escape into the cœlomic fluid and there develop. When mature they leave the body through the nephridia. *Bonellia* and *Hamingia* are very interesting examples of sexual dimorphism. The female has the normal Echiuroid structure, but the male is reduced to a minute, flattened, planarian-like organism, which passes its life usually in the company of two or three others in a special recess of the nephridia of the female. Its structure may be gathered by a reference to Fig. 3.

*Larva.*—The larva is a typical trochosphere, which, although of a temporary character, shows a distinct segmentation of the mesoblast, of the nervous system, and of the ciliated and pigmented structures in the skin, resembling that of Chætopods. The preoral lobe persists as the proboscis. The sexes of the larvæ are not determinable in the early stages, but when a certain growth has been reached in *Bonellia* the males seek the proboscis of the adult females, and passing into the mouth undergo there the transformation into the planarian-like parasite which is the fully-formed male. This now creeps along the body of the female and takes up its home in her nephridia.

*Classification and Distribution.*—The Echiuroidea consists of the following genera:—(1) *Bonellia* (Rol.), with four species, widely distributed, but inhabiting the temperate and warmer waters of each hemisphere. (2) *Echiurus* (Guérin-Méneville), with four species. This genus reaches from the Arctic waters of both hemispheres into the cooler temperate regions. (3) *Hamingia* (Kor. and Dan.), with one species, which has been taken in the Arctic Sea and the Hardanger Fjord. (4) *Saccosoma* (Kor. and Dan.) was described from a single specimen dredged about half-way between Iceland and Norway. (5) *Thalassema* (Gaertner, Lamarck), with twenty-one species. This genus is in the main a denizen of the warmer waters of the globe. Sixteen species are found only in tropical or subtropical seas, three species are Mediterranean (*Mt. Stat. Neapel*, 1899), whilst three species are from the eastern Atlantic, where the temperature is modified by the Gulf Stream (Shipley; see Willey's *Zoological Results*, part iii., 1899; *Proc. Zool. Soc. Lond.*, 1898, 1899; and *Cambridge Natural History*, ii.). The following are found in the British area:—*E. pallasii* (Guérin-Méneville), *Th. neptuni* (Gaertner), and *Th. lankesteri* (Herdman, *Q.J.M.S.*, 1898).

*Affinities.*—The occurrence of trochosphere larva and the temporary segmentation of the body have led to the belief that the Echiuroids are more nearly allied to the Annelids than to any other phylum. This view is strengthened by certain anatomical and histological re-

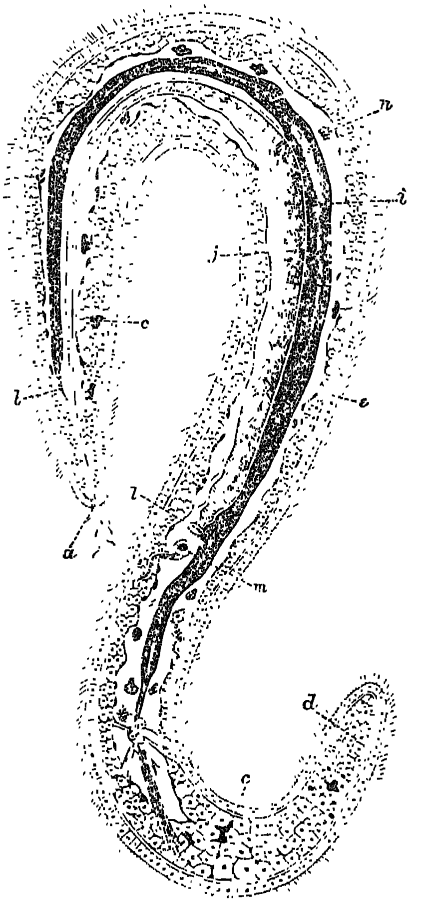

FIG. 3.—Adult male, *Bonellia viridis*, Rol. The original was 1·5 mm. long. The nervous system is not shown. (*After Selenka.*) *a*, generative pore with spermatozoa coming out; *b*, anterior blind end of intestine attached to the parenchymatous tissue by muscular strands; *c*, green wandering cells containing chlorophyll; *d*, parenchymatous connective-tissue; *e*, epidermis; *i*, intestine; *j*, vas deferens; *l*, internal opening of vas deferens; *m*, the left anal vesicle; *n*, spermatozoa in the body-cavity.

semblances to the genus *Sternaspis*, which in one species, *S. spinosa*, is said to carry a bifid proboscis resembling that of the Echiuroids. The relationship with the Sipunculoidea and the Priapuloidea are discussed in the article SIPUNCULOIDEA. (A. E. S.)

**Echuca,** a borough of Victoria, Australia, in the county of Rodney, on the river Murray, across which it is connected by bridge with Moama, which has railway connexion with Deniliquin, New South Wales. The town is the terminus of the Murray River Railway and the entrepôt of the overland intercolonial trade, and has large wool stores. The district, a rich agricultural one, is noted for its vineyards. Altitude, 314 feet. Mean temperature for the year, 58°·6 F.; for January, 71°·6; for July, 44°·7. Population (1881), 4789; (1901), 4083.

**Eckernförde,** a town of Prussia, province of Schleswig-Holstein, on a bay of the Baltic, 20 miles by rail north-west from Kiel. It has a good harbour, fishing, trade in agricultural products, and production of tobacco, salt, and iron goods. There are an architects' school and a teachers' seminary. The place suffered from a sea-flood in 1872. Population (1885), 5604; (1900), 6719.

**Eclipse.**—The general subject of eclipses, and the conditions under which they may occur, were fully treated in the article ASTRONOMY (*Ency. Brit.* vol. ii.). To that article nothing need be added on the subject of eclipses of the moon, and the present article is therefore confined to eclipses of the sun, especially those which are total.

***Elements of eclipses.***

The complete computation of the circumstances of an eclipse *ab initio* requires three distinct processes. The geocentric position of the sun and moon have first to be computed from the tables of the motions of those bodies. The second step is to compute certain elements of the eclipse from these geocentric positions. The third step is from these elements to compute the circumstances of the eclipse for the earth generally, or for any given place on its surface. The national Astronomical Ephemerides, or "Nautical Almanacs," give in full the geocentric positions of the sun and moon from at least the early part of the 19th century to an epoch three years in advance of the date of publication. It is therefore unnecessary to undertake the first part of the computation except for dates outside the limits of the published ephemerides, and for many years to come even this computation will be unnecessary, because tables giving the elements of eclipses from the earliest historic periods up to the 22nd century have been published by Oppolzer and Newcomb. We shall therefore confine ourselves to a statement of the eclipse problem and of the principles on which such tables rest.

Two systems of eclipse elements are now adopted in the ephemerides and tables; the one, that of Bessel, is used in the English, American, and French ephemerides, the other —Hansen's—in the German and in the eclipse tables of Oppolzer. The two have in common certain fundamental geometric constructions. A fundamental axis of reference in both systems is the line passing through the centres of the sun and moon; this is the common axis of the shadow cones, which envelop simultaneously the sun and moon (see Fig. 37, *Ency. Brit.* vol. ii. p. 803). The surface of one of these cones, that of the umbra, is tangent to both bodies externally. This cone comes to a point at a distance from the moon nearly equal to that of the earth. Within it the sun is wholly hidden by the moon. Outside the umbral cone is that of the penumbra, within which the sun is partially hidden by the moon. The condition that the two bodies shall appear in contact, or that the eclipse shall begin or end at a certain moment, is that the surface of one of these cones shall pass through the place of the observer at that moment. Let a plane, which we call the fundamental plane, pass through the centre of the earth perpendicular to the shadow axis. On this plane the centre of the earth is taken as an origin of rectangular coordinates. The axis of Z is perpendicular to the plane, and therefore parallel to the shadow axis; that of Y and Z lie in the plane. In these fundamental constructions the two methods coincide. They differ in the direction of the axis of Y and Z in the fundamental plane. In Bessel's method, which we shall first describe, the intersection of the plane of the earth's equator with the fundamental plane is taken as the axis of X. The axis of Y is perpendicular to it, the positive direction being towards the north. The Besselian elements of an eclipse are then:—$x$, $y$, the coordinates of the shadow axis on the fundamental plane; $d$, the declination of that point in which the shadow axis intersects the celestial sphere; $\mu$, the Greenwich hour angle of this point; $l$, the radius of the circle in which the penumbral or outer cone intersects the fundamental plane; and $l'$, the radius of the circle in which the inner or umbral cone intersects this plane, taken positively when the vertex of the cone does not reach the plane, so that the axis must be produced, and negatively when the vertex is beyond the

plane. It will be noticed that, in the first case, the eclipse appears annular to an observer at the point where the shadow axis intersects the fundamental plane, and in the second case total. But since an observer on the surface of the earth is nearer to the moon than the fundamental plane is, it may happen that an eclipse which is annular on the plane will be total to the observer on the earth's surface.

Hansen's method differs from that of Bessel in that the ecliptic is taken as the fundamental plane instead of the equator. The axis of X on the fundamental plane is parallel to the plane of the ecliptic; that of Y perpendicular to it. The other elements are nearly the same in the two theories. As to their relative advantages, it may be remarked that Hansen's co-ordinates follow most simply from the data of the tables, and are necessarily used in eclipse tables, but that the subsequent computation is simpler by Bessel's method. Its use, in case Hansen's form is used at first, requires merely the transformation of co-ordinates from the ecliptic to the equator. The eclipse tables of Oppolzer and Newcomb give the data for computing the ecliptic Y-co-ordinate at the moment T of true conjunction of the sun and moon in longitude. This co-ordinate is called B by Oppolzer and $y^\circ_2$ by Newcomb, and is expressed by Oppolzer in the form $B = p \sin P$. The tables also give, for the moment T, the value of $x^1_2$ or $\Delta L$, the hourly motion of the X-co-ordinate. Oppolzer gives separately data for $\Delta B$, the hourly motion of B, while Newcomb determines the motion of the shadow-axis from $x^1_2$ and the angle, assumed constant, which the path makes with the X-axis. An approximate value of the sun's longitude (L or ☉) and of the angle between the shadow-axis and the equator ($\delta$ [Delta] or $d$) is also found. Oppolzer uses these elements in the subsequent computation, while Newcomb transforms $x_2$ and $y_2$ into $x_1$ and $y_1$, the Besselian co-ordinates, which are to be used in the subsequent work.

Several problems are involved in the complete computation of an eclipse from the elements. First, from the values of the latter at a given moment to determine the point, if any, at which the shadow-axis intersects the surface of the earth, and the respective outlines of the umbra and penumbra on that surface. Within the umbral curve the eclipse is annular or total outside of it and within the penumbral curve the eclipse will be partial at the given moment. The penumbral line is marked from hour to hour on the maps given annually in the American Ephemeris. Second, a series of positions of the central point through the course of an eclipse gives us the path of the central point along the surface of the earth, and the envelopes of the penumbral and umbral curves just described are boundaries within which a total, annular, or partial eclipse will be visible. In particular, we have a certain definite point on the earth's surface on which the edge of the shadow first impinges; this impingement necessarily takes place at sunrise. Then passing from this point, we have a series of points on the surface at which the elements of the shadow-cone are in succession tangent to the earth's surface. At all these points the eclipse begins at sunrise until a certain limit is reached, after which, following the successive elements, it ends at sunrise. At the limiting point the rim of the moon merely grazes that of the sun at sunrise, so that we may say that the eclipse both begins and ends at that time. Of course the points we have described are also found at the ending of the eclipse. There is a certain moment at which the shadow-axis leaves the earth at a certain point, and a series of moments when, the elements of the penumbral cone being tangent to the earth's surface, the eclipse is ending at sunset. Three cases may arise in studying the passage of the outlines of the shadow over the earth. It may be that all the elements of the penumbral cone intersect the earth. In this case we shall have both a northern and southern limit of partial eclipse. In the second case there will be no limit on the one side except that of the eclipse beginning or ending at sunrise or sunset. Or it may happen, as the third case, that the shadow-axis does not intersect the earth at all; the eclipse will then not be annular or total at any point, but at most only partial.

The third problem is, from the same data, to find the circumstances of an eclipse at a given place—especially the times of beginning and ending, or the relative positions of the sun and moon at a given moment. Reference to the formulæ for all these problems will be given in the bibliography of the subject.

*Recurrence of eclipses.*

There are two well-marked periods in which eclipses recur at nearly the same distance from a node of the moon's orbit, one of 223 lunations, the other of 358. At the end of the latter period the eclipse recurs at the opposite node, and at the end of two periods, at the same node. The length of this period is 10,571·95 days, or 29 Julian years less 20·30 days. Hence 18 periods make 521 years, so that at the end of this time the eclipse recurs on the same day of the year. In the mean, the time of recurrence is so nearly at the same distance from the node that we find each central eclipse visible at our time to be one of an unbroken series extending from the earliest historic times to the present, at intervals equal to the length of the period. For example, starting from the eclipse of Nineveh, 763 B.C., June 15, recorded on the Assyrian tablets, we find eclipses on May 27, 734 B.C., May 7, 705 B.C., and so on in an unbroken series to 1843, 1872, and 1901, the last being the 93rd of the series. Those at the ends of 18 periods occurred on June 15, O.S., of each of the years 763, 242 B.C., A.D. 280, 801, 1322, and 1843. As the lunar perigee moves through 242°·4 in a period, the eclipses will vary from total to annular, but at the end of 3 periods the perigee is only 7°·1 in advance of its original position relative to the node. Hence in a series including every third eclipse the eclipses will be of the same character through a thousand years or more. Thus the eclipses of 1467, 1554, 1640, 1727, 1814, 1901, 1988, &c., are total.

The length of the other period, called the Saros, is 6585⅓ days, or 18 years and 11 or 12 days. The fact that eclipses recur at the end of this period has been known from ancient times. Owing to the fractional excess of ⅓ of a day in the period, each recurring eclipse takes place about 120° farther west in longitude than the preceding one of the series, and is therefore not generally visible in the same region. During the course of a Saros there are 223 lunations and 19 returns of the sun to each of the moon's nodes. The clearest idea of the law of recurrence thus arising may be gained by the conception of conjunction-points of the moon and sun in the following way:—

Imagine a circle, having the earth in its centre, to be situated in the mean plane of the moon's orbit, and to be fixed to the node of the orbit so as to make one revolution in its plane around its centre in the same period as the revolution of the node (about 18$^y$·6). Imagine also that, as the sun and moon revolve, we mark on this circle the points in the direction of which the mean conjunctions of the two bodies occur. These conjunction-points will fall at various points of the circle until the end of the Saros. Then after 223 conjunctions the 224th will fall very near the first. The deviation will be somewhat less than half a degree. To make it fall exactly upon the first we have only to give our circle, conceived as bearing the conjunction-points, a motion equal to this deviation, or, speaking more exactly, a uniform retrograde revolution through 0°·476 in one period. The amount of this motion was

slightly less in former centuries, and will increase a little in the future owing to the acceleration of the moon's motion. When this motion is assigned to the circle eclipses will always take place at one or the other of these 223 points, but will, of course, be confined to those which lie near the moon's node. The latter will now move over the system of points at the rate of $0^\circ{\cdot}476$ per period. This will carry the node from one conjunction-point to the next in about 61 years.

We may classify eclipses according to the conjunction-point at which they occur. As any one such point slowly approaches the node the successive eclipses, separated by an interval of one Saros, which occur at that point, will fall continually nearer the node until the conjunction-point passes it, near which time they will be central. After passing the node a certain distance the eclipse will cease to be central, and become partial until at length the distance of the point from the node will be such that the series will cease. The entire duration of each series is more than a thousand years. The introduction of the period in question would have no special significance but for one important circumstance. It happens that the lapse of one Saros brings together not only the sun and moon, but approximately the lunar perigee and the mean anomaly of the sun. The change in the former is less than three degrees, in the latter between ten and eleven degrees. The character of an eclipse, whether annular or total, and, if total, the duration of the total phase, depend on the position of the lunar and solar perigees relatively to the conjunction-point. It follows that each recurring eclipse will be of the same general character as that which preceded it. If the duration of totality of the latter is remarkably long, the same will be true of the recurring eclipse. This fact enables us, by the aid of suitable tables, to select almost at sight eclipses of long duration in the past or future.

**Notable eclipses.**

The following is a brief chronological enumeration of those total eclipses of the sun which are of interest, either from their historic celebrity or the nature of the conclusions derived from them. In numbering the years before the Christian era the astronomical nomenclature is used, in which the number of the year is one less than that used by the chronologists. The Chinese eclipses are passed over, owing to the generally doubtful character of the records pertaining to them.

762 B.C., June 14; a total eclipse recorded at Nineveh. Computation from the modern tables shows that the path of totality passed about 100 miles or more north of Nineveh.

584 B.C., May 28; the celebrated eclipse of Thales. An account of this eclipse will be found in the article THALES (*Ency. Brit.* vol. xxiii.).

556 B.C., May 19; the eclipse of Larissa. The modern tables show that the eclipse was not total at Larissa, and the connexion of the classical record with the eclipse is doubtful.

430 B.C., August 3; eclipse mentioned by Thucydides, but not total by the tables.

399 B.C., June 21; eclipse of Ennius. Totality occurred immediately after sunset at Rome. The identity of this eclipse is doubtful.

309 B.C., August 14; eclipse of Agathocles. This eclipse would be one of the most valuable for testing the tables of the moon, but for an uncertainty as to the location of Agathocles, who, at the time of the occurrence, was at sea on a voyage from Syracuse to Carthage.

Ginzel (*Spezieller Kanon der Finsternisse*) has collected a great number of passages from classical authors supposed to refer to eclipses of the sun or moon, but the difficulty of identifying the phenomenon is frequently such as to justify great doubt as to the conclusions. In a few cases no eclipse corresponding to the description can be found by our modern table to have occurred, and in others the latitude of interpretation and the uncertainty of the date are so wide that the eclipse cannot be identified.

Of mediæval eclipses we mention only the dates of those visible in England, referring for details to the works mentioned in the bibliography. The letter C following a date shows that the eclipse is mentioned in the Anglo-Saxon Chronicles. The dates in question are:—

A.D. 538, February 15, C. (partial).
540, June 12, C. (partial).
594, July 23.
A.D. 603, August 12.
639, September 3.
664, May 1, C.
A.D. 733, August 14 (annular).
764, June 4 (annular).
878, October 29, C.
885, June 15.
1023, January 24.
A.D. 1133, August 1, C.
1140, March 20, C.
1185, May 1, C.
1191, June 23, C. (annular).
1330, July 16.

Besides these, the tables show that the shadow of the moon passed over some part of the British Islands on 1424, June 26; 1433, June 17; 1598, March 6; 1652, April 8; 1715, May 2; 1724, May 22. The next dates are 1927, June 29, when a barely total eclipse will be seen soon after sunrise in the northern counties near the Scottish Border, and 1999, August 11, when the moon's shadow will graze England at Land's End.

**Eclipses of the 19th and 20th centuries.**

We give below, in tabular form, a list of the principal total eclipses between 1800 and 1970, omitting a few visible only in the extreme polar regions, and some others of which the duration is very short. The eclipses are classified in the table according to their position in the eighteen-years period, so that the table shows the successive eclipses occurring at this interval. In this way it is possible for the reader to continue the table, with a considerable degree of approximation, for several periods, while the law of recurrence and the gradual change in the character of the eclipse are made evident at sight. The first column gives the date of the point on the earth's surface at which the eclipse is central at noon. The next two columns give the position of this point to the nearest degree. As the date in the first column changes at 180° long. from Greenwich, the integer dates are not at equal intervals, and therefore the fourth column shows the Greenwich astronomical time of conjunction in longitude. The next column gives the duration of the total phase at the noon-point; this is sometimes $0^{m}{\cdot}1$ less than the greatest duration. The eclipses of each period occur near the same node of the moon, which is indicated at the head of the series. By the central date of the series is meant that date when an eclipse occurred, in the mean, nearest to the node. This is, of course, one of the dates of the series.

*Total Eclipses of the Sun, 1800 to 1970, classified by the 18-Years Period.*[1]

It will be noticed that two of these series, VI. and VII., will be, or have been, notable for the long duration of totality. Those of 1937 and 1955 fall not more than $20^s$ below the absolute maximum of $7^m\ 30^s$. But series IV. will increase to a yet greater duration, reaching in 2150, June 25, a duration of about $7^m\ 16^s$, and on 2168, July 5, a duration of $7^m\ 28^s$, the longest in human history. The first of these will pass over the Pacific Ocean; the second over the southern part of India, near Madras.

*Physical Phenomena of Recent Total Eclipses.*

As the moon advances on the solar disc, the sharp and rugged edge of the lunar disc is in strong contrast to the soft and uniform outline of the sun's limb. Some little time before the commencement of the total phase the entire outline of the moon may be distinguished, that part off the sun being seen by its cutting off the faint light of the corona. A few seconds before the commencement of the total phase the red light of the chromosphere becomes visible, and will be seen most distinctly as continuations of the solar crescent at its two ends. Owing to the inequalities of the lunar surface, the diminution of the solar crescent does not go on with perfect uniformity, but, just before the last moment, what remains of it is generally broken up into separate portions of light, which, magnified and diffused by the irradiation of the telescope, present the phenomenon long celebrated under the name of "Baily's beads." These were so called because minutely and vividly described by Baily as he observed them during the annular eclipse of May 15, 1836, when he compared them to a string of bright beads, irregular in size and distance from each other. The disappearance of the last bead is commonly taken as the beginning of totality. An arc of the chromosphere will then be visible at the point of disappearance, the length and duration of which will depend on the apparent diameter of the moon as compared with that of the sun, being greater in length and longer seen as the excess of diameter of the moon is less. The red prominences may now generally be seen here and there around the whole disc of the moon, while the effulgence of soft light called the corona surrounds it on all sides. Before the invention of the spectroscope, observers of total eclipses could do little more than describe in detail the varying phenomena presented by the prominences and the corona. Drawings of the latter showed it to have the appearance of rays surrounding the dark disc of the moon, quite similar to the glory depicted by the old painters around the head of a saint. The discrepancies between the outlines as thus pictured, not only at different times, but by different observers at the same time and place, are such as to show that little reliance can be placed on the details represented by hand drawings.

During the eclipse of July 8, 1842, the shadow of the moon passed from Perpignan, France, through Milan and Vienna, over Russia and Central Asia, to the Pacific Ocean. Very detailed physical observations were made, but none which need be specially mentioned in the present connexion. The eclipse of July 28, 1851, was total in Scandinavia and Russia. It was observed in the former region by many astronomers, among them Airy and Dawes. It was especially noteworthy for the first attempt to photograph such a phenomenon. A daguerreotype clearly showing the protuberances was taken by Berkawski at the Observatory of Königsberg. An attempt by Majocchi to daguerreotype the corona was a failure. Photographs of the eclipse of July 18, 1860, were taken by Padre Secchi and Mr Warren De La Rue, which showed the prominences well, and proved that they were progressively obscured by the edge of the advancing moon. It was thus shown that they were solar appendages, and did not belong to the moon, as had sometimes been supposed. The corona was

barely visible on De La Rue's plates, but those of Secchi showed it, with its rifts and the bases of the tall coronal wings, to about 15′ from the sun's limb. The sketches taken at this eclipse proved that the corona extended in some regions 1° from the sun's limb. As the sensitiveness of photographic plates has increased, they have gradually been wholly relied upon for information respecting the corona, so that at the present time naked-eye descriptions are regarded as of little or no scientific value. Owing to the great contrast between the brilliancy of the coronal light at its base and its increasing faintness as it extends farther from the sun, no one photograph will bring out all the corona. An exposure of one or two seconds is ample to show the details of the inner corona to the best advantage, while longer exposures give greater extent of the brighter portions. The most extended streamers are very little brighter than the sky, and must be photographed with short exposures.

The first application of the spectroscope to the phenomenon was made during the total solar eclipse of August 18, 1868, by Janssen and other observers in India. By them was made the capital discovery that the red solar prominences give a spectrum of bright lines, and are therefore immense masses of incandescent gases, chiefly hydrogen and the vapours of calcium and helium. Janssen also found that this bright-line spectrum could be followed after the eclipse was over, and, in fact, could be observed at any time when the air was sufficiently transparent. By one of those remarkable coincidences which frequently occur in the history of science, this last discovery was made independently by Lockyer in England before the news of Janssen's success had reached him. It was afterwards found that, by giving great dispersing power to the spectroscope, the prominences could be observed in a wide slit, in their true form. At this eclipse the spectrum of the corona was also observed, and was supposed to be continuous, while polariscopic observation by Lieutenant Campbell showed it polarized in planes passing through the sun's centre. The conclusion from these two observations was that the light was composed, at least in great part, of reflected sunlight. At the total eclipse of August 7, 1869, it was independently found by Professors Young of Princeton and Harkness of Washington that the continuous spectrum of the corona was crossed by a bright line in the green, which was long supposed to be coincident with 1474 of Kirchhoff's scale. This coincidence is, however, now found not to be real, and the line cannot be identified with that of any terrestrial substance. The name "coronium" has therefore been given to the supposed gas which forms it. It is now known that 1474 is a double line, one component of which is produced by iron, while the other is of unknown origin. The wave-length of the principal component is 5317, while that of the coronal line was found at the eclipses of 1896 and 1898 to be 5303.

The eclipse of December 28, 1870, passed over the south-western corner of Spain, Gibraltar, Oran, and Sicily. It is memorable for the discovery by Young of the "reversing layer" of the solar atmosphere. This term is now applied to a shallow stratum immediately above the photosphere, the absorption of which produces the principal dark lines of the solar spectrum, but which, being incandescent, gives a spectrum of bright lines by its own light when the light of the sun is cut off. This layer is much thinner than the chromosphere, and may be considered to form the base of the latter. Owing to its thinness, the phenomenon of the reversed bright lines is almost instantaneous in its nature, and can only be observed for a considerable period near the edge of the shadow-path where the moon advances but little beyond the solar limb. Elsewhere it is a mere flash. Young also at this eclipse saw bright hydrogen lines when his spectroscope was directed to the centre of the dark disc of the moon. This can only be attributed to the reflection of the light of the prominences and chromosphere from the atmosphere between us and the moon. The coronal light as observed in the spectroscope may thus be regarded as a mixture of true coronal light with chromospheric light reflected from the air, and it is therefore probable that the H and K (calcium) lines of the coronal spectrum are not true coronal lines, but chromospheric.

At the eclipse of December 12, 1871, visible in India and Australia, Janssen observed, as he supposed, some of the dark lines of the solar spectrum in the continuous spectrum of the corona, especially D, *b*, and G. This would show that an important part of the coronal light is due to reflected sunshine. This feature of the spectrum, however, is doubtful in the most recent photographs under the best conditions. At this eclipse the remarkable observation was also made by Herschel and Tennant that the characteristic line of the coronal spectrum is as bright in the dark rifts of the corona as elsewhere. This would show that the gas coronium does not form the streamers of the corona, but is spherical in form and distributed uniformly about the sun. Photographs were also taken on wet plates by a party in Java and by the parties of Lord Lindsay (at Baikul, India) and of Colonel Tennant (at Dodabetta). The Baikul and Dodabetta photographs were of small size (moon's diameter = $\frac{3}{10}$ inch), but of excellent definition. A searching study was made of them by Messrs Ranyard and Wesley (see *Memoirs R.A.S.* vol. xli. 1879), and for the first time a satisfactory representation of the corona was obtained. The drawings in the volume quoted show its polar rays, wings, interlacing filaments, and rifts as they are now known to be, as well as the forms and details of the prominences.

The eclipse of April 16, 1874, was observed in South Africa by Mr E. J. Stone, Astronomer-Royal at the Cape, who traced the coronal line about 30′ (430,000 miles) from the sun's limb. The visual corona was seen to extend in places some 90′ from the limb.

The eclipse of April 6, 1875, was observed in Siam by Sir J. Norman Lockyer and Professor Schuster. Their photographs showed the calcium and hydrogen lines in the prominence spectrum.

The eclipse of July 29, 1878, was thoroughly observed by many astronomers in the United States along a line extending from Wyoming to Texas. A number of the stations were at high altitudes (up to 14,000 feet), and the sky was generally very pure. The visible corona extended on both sides of the sun along the ecliptic for immense distances—at least twelve lunar diameters, about eleven million miles. Photographs taken by the parties of Professors Hall and Harkness gave the details of the inner corona and of the polar rays, showing the filamentous character of the corona, especially at its base in the polar regions. A photograph taken by the party of Professor Holden showed the outer corona to a distance of 50′ from the moon's limb. The bright-line spectrum of the corona was excessively faint and, as the solar activity (measured by sun-spot frequency) was near a minimum, it was concluded that the brilliancy of the coronium line varied in the sun-spot period, a conclusion which subsequent eclipse observations seem to have verified. It is not yet certain that the other coronal spectrum lines vary in the same way.

The eclipse of May 17, 1882, was observed in Egypt. On the photographs of the corona the image of a bright comet was found, the first instance of the sort. (A faint comet was found on the plates of the Lick Observatory eclipse expedition to Chile in 1893.) The slitless spectro-

scope showed the green line (coronium) and $D_3$ (helium) in the coronal spectrum.

The eclipse of May 6, 1883, was observed from a small coral atoll in the South Pacific Ocean by parties from America, England, France, Austria, and Italy. A thorough search was made by Holden (with a six-inch telescope) for an intra-Mercurial planet, without success, during an unusually long totality (5 m. 23 s.). Palisa also searched for such a planet. Janssen again reported the presence of dark lines in the coronal spectrum. "White" prominences were seen by Tacchini.

The eclipse of August 29, 1886, was observed in the West Indies. The English photographs of the corona, taken with a slitless spectroscope, show the hydrogen lines as well as K and *f*. Tacchini devoted his attention to the spectra of the prominences, and showed that their upper portions contained no hydrogen lines, but only the H and K lines of calcium. He also observed a very extensive "white" prominence. It was shown on the photographs of the corona, but could not be seen in the H$\alpha$ line with the spectroscope. It has been suggested by Professor G. E. Hale that the colour of a "white" prominence may be due to the fact that the H and K lines (calcium) are of their normal intensity, while the less refrangible prominence lines are, from some unknown cause, comparatively faint. It is known that the intensity of such lines does, in fact, vary, though it is not yet certain that the "white" prominences are produced in this way. The subject is one demanding further observation. High prominences are generally "white" at their summits, "red" at their bases. The Harvard College Observatory photographs show the corona out to 90′ from the moon's limb, though no detail is visible beyond 60′. Mr W. H. Pickering made a series of photographic photometric measures of the corona, some of which are given below, together with results deduced by Holden from the eclipses of January and December 1889 :—

| | August 1886. | January 1889. | December 1889. |
|---|---|---|---|
| Intrinsic actinic brilliancy of the brightest parts of the corona . | 0·031 | 0·079 | 0·029 |
| Do. of the polar rays . . | ... | 0·053 | 0·016 |
| Do. of the sky near the sun | 0·0007 | 0·0050 | 0·0009 |
| Ratio of intrinsic brilliancy of the brightest parts of the corona to that of the sky (actinic) . . | 44 to 1 | 16 to 1 | 32 to 1 |
| Magnitude of the faintest star shown on the eclipse negatives . | ... | 2·3 | ... |

The results in the first and third columns are derived from plates taken in a very humid climate, and are not very different.

The eclipse of August 19, 1887, was total in Japan and Russia, but cloudy weather prevented successful observations except in Siberia and Eastern Russia.

The eclipse of January 1, 1889, was observed in California and Nevada by many American astronomers. The photographs of the corona, especially those by Charoppin and Barnard, show a wealth of detail. Those of Barnard, of the Lick Observatory party, were studied by Holden, and exhibited the fact that rays, like the "polar-rays," extended all round the sun, instead of being confined to the polar regions only. The outer corona was registered out to 100′ from the moon's limb on Charoppin's negatives, to 130′ on those of Lowden and Ireland. On other plates the outline of the moon is visible projected on the corona before totality began. The spectrum of the corona showed few bright lines besides those of coronium and hydrogen.

The eclipse of December 22, 1889, was observed in Cayenne, S.A., by a party from the Lick Observatory under rather unfavourable conditions. Expeditions sent to Africa were baffled by cloudy weather. Father Perry observed at Salute Islands, French Guiana, and obtained some photographs of value. The effort cost him his life, for he died of malarial fever five days after the eclipse.

The eclipse of April 16, 1893, was observed by British and French parties in Africa and Brazil, and by Professor Schalberle of the Lick Observatory in Chile. The Chile photographs of the corona were taken with a lens of 40 feet focus, and are extremely fine. They show a faint comet near the sun. No great extensions to the corona were shown on any of the negatives, or seen visually, though they were specially looked for by British parties. The neighbourhood of the sun was carefully examined by Bigourdan without finding any planet. The spectrum of the corona was the usual one. The following lines were photographed in slitless spectroscopes, and undoubtedly belong to the corona :—W. L. 3987; 4086; 4217; 4231; 4240; 4280; 4486; 5303 (the last number is the wave-length of the green coronium line). All of these have been seen in slit spectroscopes also. It is possible that two lines observed by Young in 1869, namely, W. L. (Ångstrom) 5450 and 5570, should be added to the list of undoubted coronal lines. It is not likely that helium or hydrogen or calcium vapour forms part of the corona. The wave-lengths of some 700 lines belonging to the chromosphere and prominences were determined by the British parties.

The eclipse of August 9, 1896, was total in Norway and Nova Zembla. The day was very unfavourable, but good photographs of the corona were obtained by Russian parties in Siberia and Lapland. Mr Shackelton, in Nova Zembla, with a prismatic camera obtained a photograph of the reversing-layer at the beginning of totality. This photograph completely confirms Young's discovery, and shows the prominent Fraunhofer lines bright, the bright lines of the chromosphere spectrum being especially conspicuous.

At the solar eclipse of January 22, 1898, the shadow of the moon traversed India from the western coast to the Himalaya. The duration of totality was about 2 m. The eclipse was very fully observed, more than 100 negatives of the corona being secured. The equatorial extension of the visible corona was short and faint, and the invisible (spectroscopic) corona was also very faint. The spectrum of the reversing-layer was successfully photographed; one set of negatives shows the polarization of one of the longest streamers of the corona, and proves the presence of dust particles reflecting solar light. The bright-line spectrum of hydrogen in the chromosphere was followed to the thirtieth point of the series, and the wave-lengths were shown to agree closely with Balmer's formula (see SPECTROSCOPE). The wave-length of coronium was found to be 5303 (not 5317 as previously supposed), and the brightness of the corona was measured. Maunder made the curious observation of coronal matter enveloping a prominence in the form of a hood.

Observations of the eclipse of May 28, 1900, were favoured in a remarkable degree by the absence of clouds. The photographs of the corona obtained by Campbell extended four diameters of the sun on the west side. The sun's edge was photographed with an objective-prism spectrograph composed of two 60° prisms in front of a telescope of 2 in. aperture and 60 in. focus. A fine photograph, 6 inches long, of the bright- and dark-line spectra of the sun's edge at the end of totality was thus obtained. It shows 600 bright lines sharply in focus besides the dark-line spectrum, to which the bright lines gave way as the sun reappeared. The coronal material radiating the green light was found to be markedly heaped up in the sun-spot regions. No dark lines were found in the spectrum of the

inner corona. Hale and Frost also photographed the combined bright- and dark-line spectra of the solar cusps at the instants before and after totality. On one photograph showing no dark lines 70 bright lines could be measured between 4070 and 4340. On another were 70 bright lines between H*b* and Hs. On a third were 266 bright lines between 4026 and 4381, and some dark lines. These lines show a marked dissimilarity from the solar spectrum.

At this eclipse the "shadow-bands" received special attention. These consist of seeming vague and rapidly moving alternations of light and shade flitting over any white surface illuminated by the sun's rays just before and after the total phase; they are probably due to a flickering of the light from the thin crescent produced by the air, in the same way that the twinkling of the stars is produced.

*References.*—The richest mine of information respecting eclipses of the sun and moon is Oppolzer's "Kanon der Finsternisse," published by the Vienna Academy of Sciences in the 52nd volume of its *Denkschriften*, Vienna, 1887. It contains elements of all eclipses both of the sun and moon, from 1207 B.C. to A.D. 2161, a period of more than thirty centuries. Appended to the tables is a series of charts showing the paths of all central eclipses visible in the northern hemisphere during the period covered by the table. The points of the path at which the eclipse occurs, at sunrise, noon, and sunset, are laid down with precision, but the intermediate points are frequently in error by several hundred miles, as they were not calculated, but projected simply by drawing a circle through the three points just mentioned. For this reason we cannot infer from them that an eclipse was total at any given place. The correct path can, however, be readily computed from the tables given in the work. Dr Eduard Mahler's memoir, "Die Centralen Sonnenfinsternisse des XX. Jahrhunderts" (*Denkschriften*, Vienna Academy, vol. xlix.), gives more exact paths of the central eclipses of the 20th century, but no maps. General tables for computing eclipses are Oppolzer's "Syzygien-tafeln für den Mond" (*Publication der Astronomischen Gesellschaft*, xvi.), and Newcomb's, in *Publications of the American Ephemeris*, vol. i. part i. Of these, Oppolzer's are constructed with greater numerical accuracy and detail, while Newcomb's are founded on more recent astronomical data, and are preferable for computing ancient eclipses. Ginzel's *Spezieller Kanon der Sonnen- und Mondfinsternisse* (Berlin, 1899) contains, besides the historical researches already mentioned, maps of the paths of central eclipses visible in the lands of classical antiquity from 900 B.C. to A.D. 500, but computed with imperfect astronomical data. Maguire, "Monthly Notices," *R.A.S.*, xlv. and xlvi., has mapped the total solar eclipses visible in the British Islands from 878 to 1724. General papers of interest on the same subject have been published by Rev. S. J. Johnson. A résumé of all the observations on the physical phenomena of total solar eclipses up to 1878, by A. C. Ranyard, is to be found in *Memoirs of the Royal Astronomical Society*, vol. xli. A very copious development of the computation of eclipses by Bessel's method is found in Chauvenet's *Spherical and Practical Astronomy*, vol. i. Hansen's method is developed in the *Abhandlungen* of the Leipzig Academy of Sciences, vol. vi. (Math.-Phys. Classe, vol. iv.). The formulæ of computation by this method are found in the introductions to Oppolzer's two works cited above. (S. N.)

**Economic Entomology** is the study of insects based on their relation to man, his domestic animals and his crops, and, in the case of those that are injurious, of the practical methods by which they can be prevented from doing harm, or be destroyed when present. In Great Britain little attention is paid to this important branch of agricultural science, but in America and the British Colonies the case is different. Nearly every State in America has its official Economic Entomologists, and nearly every one of the British Crown Colonies is provided with one or more able men who help the agricultural community to battle against the insect pests. Most, if not all, of the important knowledge of remedies comes from America, where this subject reaches the highest perfection; even the life-histories of some of the British pests have been traced out in the United States and British Colonies more completely than at home, from the creatures that have been introduced from Europe.

Some idea of the importance of this subject may be gained from the following figures. The estimated loss by the Vine Phylloxera in the Gironde alone was £32,000,000; for all the French wine districts £100,000,000 would not cover the damage. It has been stated on good evidence that a loss of £7,000,000 per annum was caused by the attack of the Ox Warble Fly on cattle in England alone. In a single season Aberdeenshire suffered nearly £90,000 worth of damage owing to the ravages of the Diamond Back Moth on the root crops; in New York State the Codling Moth caused a loss of $3,000,000 to apple growers. Yet these figures are nothing compared to the losses due to Scale Insects, Locusts, and other pests.

The most able exponent of this subject in Great Britain was John Curtis, whose treatise on *Farm Insects*, published in 1860, is still the standard British work dealing with the insect foes of corn, roots, grass, and stored corn. The most important works dealing with fruit and other pests come from the pens of Saunders, Lintner, Riley, Slingerland, and others in America and Canada, from Taschenberg, Lampa, Reuter, and Kollar in Europe, and from French, Froggatt, and Tryon in Australia. It was not until the last quarter of the 19th century that any real advance was made in the study of economic entomology. Among the early writings, besides the book of Curtis, there may also be mentioned a still useful little publication by Pohl and Kollar, entitled *Insects Injurious to Gardeners, Foresters, and Farmers*, published in 1837, and Taschenberg's *Praktische Inseektenkunde*. American literature began as far back as 1788, when a report on the Hessian Fly was issued by Sir Joseph Banks; in 1817 Say began his writings; while in 1856 Asa Fitch started his report on the "Noxious Insects of New York." Since that date the literature has largely increased. Among the most important reports, &c., may be mentioned those of Riley, published by the U.S. Department of Agriculture, extending from 1878 to his death, in which is embodied an enormous amount of valuable matter. At his death the work fell to Professor Howard, who constantly issues brochures of equal value in the form of Bulletins of the State Department of Agriculture. The chief writings of Lintner extend from 1882 to 1898, in yearly parts, under the title of *Reports on the Injurious Insects of the State of New York*. Another author whose writings rank high on this subject is Slingerland, whose investigations are published by Cornell University. Among other Americans who have largely increased the literature and knowledge must be mentioned Webster and Felt. In 1883 appeared a work on fruit pests by William Saunders, which mainly applies to the American continent; and another small book on the same subject was published in 1898 by Miss Ormerod, dealing with the British pests. In Australia Tryon published a work on the *Insect and Fungus Enemies of Queensland* in 1889. Many other papers and reports are being issued from Australia, notably by Froggatt in N.S. Wales. At the Cape excellent works and papers are prepared and issued by the Government Entomologist, Dr Lounsbury, under the auspices of the Agricultural Department; while from India we have Cotes's *Notes on Economic Entomology*, published by the Indian Museum in 1888, and other works, especially on tea pests.

Injurious insects occur among the following orders:—*Coleoptera*, *Hymenoptera*, *Lepidoptera*, *Diptera*, *Hemiptera* (both *heteroptera* and *homoptera*), *Orthoptera*, *Neuroptera*, and *Thysanoptera*. The order *Aptera* also contains a few injurious species.

Among the *Coleoptera* or Beetles there is a group of world-wide pests, the *Elateridæ* or Click Beetles, the adults of the various "Wireworms." These insects in the larval or wireworm stage attack the roots of plants, eating them away below the ground. The eggs deposited by the beetle in the ground develop into yellowish brown wire-like grubs with six legs on the first three segments and a ventral prominence on the anal segment. The life of these subterranean pests differs in the various species; some undoubtedly (*Agriotes lineatum*) live for three or four years, during the greater part of which time they gnaw away at the roots of plants, carrying wholesale destruction before them. When mature they pass deep into the ground and pupate, appearing after a few months as the click beetles (Fig. 1). Most crops are attacked by them, but they are particularly destructive to wheat and other cereals. With such subterranean pests little can be done beyond

rolling the land to keep it firm, and thus preventing them from moving rapidly from plant to plant. A few crops, such as mustard, seem deleterious to them. By growing mustard and ploughing it in green the ground is made obnoxious to the wireworms, and may even be cleared of them. For root feeders, bisulphide of carbon injected

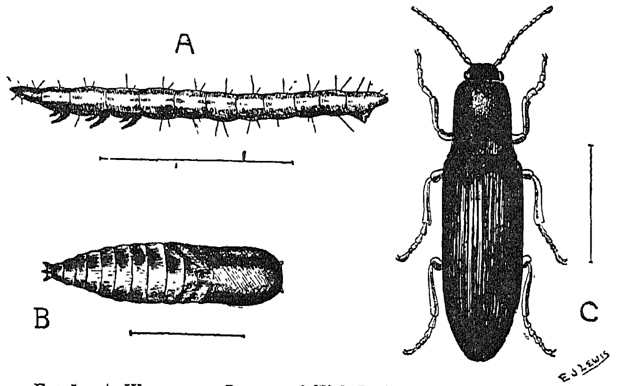

FIG. 1.—A, Wireworm; B, pupa of Click Beetle; C, adult Click Beetle (*Agriotes lineatum*).

into the soil is of particular value. One ounce injected about two feet from an apple tree on two sides has been found to destroy all the ground form of the Woolly Aphis. In garden cultivation it is most useful for wireworm, used at the rate of 1 ounce to every 4 square yards. It kills all root pests.

In Great Britain the Flea Beetles (*Halticidæ*) are one of the most serious enemies; one of these, the Turnip Flea (*Phyllotreta nemorum*), has in some years, notably 1881, caused more than £500,000 loss in England and Scotland alone by eating the young seedling turnips, cabbage, and other *Cruciferæ*. In some years three or four sowings have to be made before a "plant" is produced enormous loss in labour and cost of seed alone being thus involved. These beetles, characterized by their skipping movements and enlarged hind femora, also attack the hop (*H. concinna*), the vine in America (*Graptodera chalybea*, Illig.), and numerous other species of plants, being specially harmful to seedlings and young growth. Soaking the seed in strong-smelling substances, such as paraffin and turpentine, has been found efficacious, and in some districts paraffin sprayed over the seedlings has been practised with decided success. This oil generally acts as an excellent preventive of this and other insect attacks.

In all climates fruit and forest trees suffer from Weevils or *Cuculionidæ*. The Plum Cuculio (*Conotrachelus nenuphar*, Herbst) in America causes endless harm in plum orchards; Cuculios in Australia ravage the vines and fruit trees (*Orthorrhinus Klugii*, Schon, and *Leptops Hopei*, Bohm, &c.). In Europe a number of "long-snouted" beetles, such as the Raspberry Weevils (*Otiorhynchus picipes*), the Apple Blossom Weevil (*Anthonomus pomorum*), attack fruit; others, as the "corn weevils" (*Calandra oryzæ* and *C. granaria*), attack stored rice and corn; while others produce swollen patches on roots (*Ceutorhynchus sulcicollis*), &c. All these Cuculionidæ are very timid creatures, falling to the ground at the least shock. This habit can be used as a means of killing them, by placing boards or sacks covered with tar below the trees, which are then gently shaken. As many of these beetles are nocturnal, this trapping should take place at night. Larval "weevils" mostly feed on the roots of plants, but some, such as the Nut Weevil (*Balaninus nucum*), live as larvæ inside fruit. Seeds of various plants are also attacked by weevils of the family *Bruchidæ*, especially beans and peas. These seed-feeders may be killed in the seeds by subjecting them to the fumes of bisulphide of carbon. The corn weevils (*Calandra granaria* and *C. oryzæ*) are now found all over the world, in many cases rendering whole cargoes of corn useless.

The most important Hymenopterous pests are the Saw-flies or *Tenthredinidæ*, which in their larval stage attack almost all vegetation. The larvæ of these are usually spoken of as "false caterpillars," on account of their resemblance to the larvæ of a moth. They are most ravenous feeders, stripping bushes and trees completely of their foliage, and even fruit. Sawfly larvæ can at once be recognized by the curious positions they assume, and by the number of pro-legs, which exceeds ten. The female lays her eggs in a slit made by means of her "saw-like" ovipositor in the leaf or fruit of a tree. The pupæ in most of these pests are found in an earthen cocoon beneath the ground, or in some cases above ground (*Lophyrus pini*). One species, the Slugworm (*Eriocampa limacina*), is common to Europe and America; the larva is a curious slug-like creature, found on the upper surface of the leaves of the pear and cherry, which secretes a slimy coating from its skin. Currant and gooseberry are also attacked by sawfly larvæ (*Nematus ribesii* and *N. ventricosus*) both in Europe and America. Other species attack the stalks of grasses and corn (*Cephus pygmæus*). Forest trees also suffer from their ravages, especially the Conifers (*Lophyrus pini*). Another group of Hymenoptera occasionally causes much harm in fir plantations, namely, the *Siricidæ* or Wood-Wasps, whose larvæ burrow into the trunks of the trees and thus kill them. For all exposed Sawfly larvæ hellebore washes are most fatal, but they must not be used over ripe or ripening fruit, as the hellebore is poisonous.

The order Diptera contains a host of serious pests. These two-winged insects attack all kinds of plants, and also animals in their larval stage. Many of the adults are bloodsuckers (*Tabanidæ*, *Culicidæ*, &c.); others are parasitic in their larval stage (*Œstridæ*, &c.). The best known dipterous pests are the Hessian Fly (*Cecidomyia destructor*), the Pear Midge (*Diplosis pyrivora*), the Fruit Flies (*Tephritis Tryoni* of Queensland and *Halterophora capitata* or the Mediterranean Fruit Fly), the Onion Fly (*Phorbia cepetorum*), and numerous corn pests, such as the Gout Fly (*Chloropstæniopus*) and the Frit Fly (*Oscinis frit*). Animals suffer from the ravages of Bot Flies (*Œstridæ*) and Gad Flies (*Tabanidæ*); while the Tsetse disease is due to the Tsetse Fly (*Glossina morsitans*), carrying the protozoa that cause the disease from one horse to another. Other flies act as disease-carriers, including the mosquitoes (*Anopheles*), which not only carry malarial germs, but also form a secondary host for these parasites. Hundreds of acres of wheat are lost annually in America by

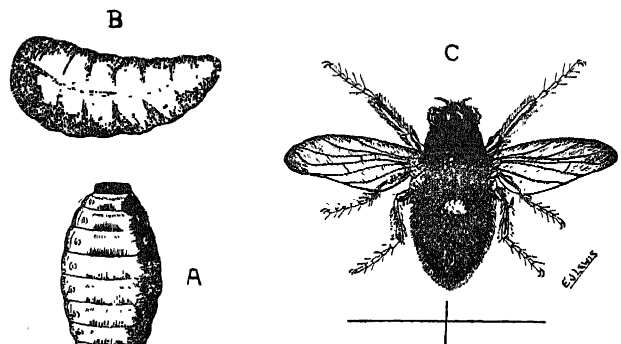

FIG. 2.—A, Ox Bot Maggot; B, puparium; C, Ox Warble Fly (*Hypoderma bovis*).

the ravages of the Hessian Fly; the Fruit Flies of Australia and South Africa cause much loss to orange

and citron growers, often making it necessary to cover the trees in muslin tents for protection. Of animal pests the Ox Warbles (*Hypoderma lineata* and *H. bovis*) are the most important (see Fig. 2). The "bots" or larvæ of these flies live under the skin of cattle, producing large swollen lumps—"warbles"—in which the "bots" mature (Fig. 2). These parasites damage the hide, set up inflammation, and cause immense loss to farmers, herdsmen, and butchers. The universal attack that has been made upon this pest has, however, largely decreased its numbers. In America cattle suffer much from the Horn Fly (*Hæmatobia serrata*). The dipterous garden pests, such as the Onion Fly, Carrot Fly, and Celery Fly, can best be kept in check by the use of paraffin emulsions and the treatment of the soil with gas-lime after the crop is lifted. Cereal pests can only be treated by general cleanliness and good farming, and of course they are largely kept down by the rotation of crops.

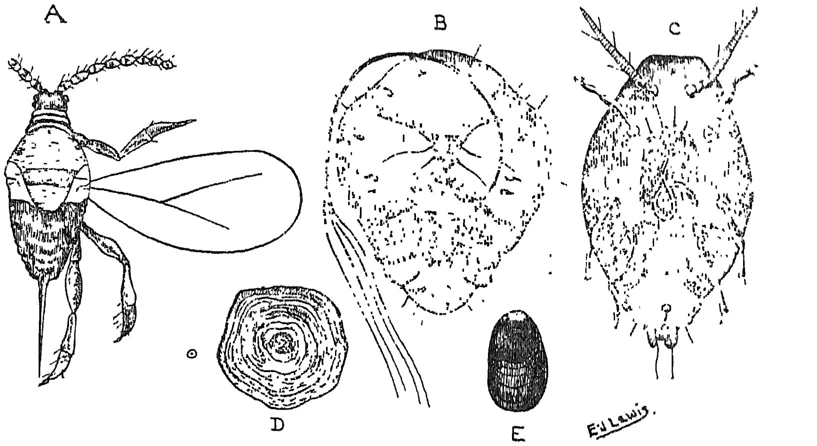

FIG. 4.—San José Scale ([illegible]). A, male scale insect; B, female; C, [illegible]; D, [illegible], E, male scale.

Lepidopterous enemies are numerous all over the world. Fruit suffers much from the larvæ of the *Geometridæ*, the so-called "Looper-larvæ" or "Canker-worms." Of these geometers the Winter Moth (*Cheimatobia brumata*) is one of the chief culprits in Europe (Fig. 3). The females in this moth and in others allied to it are wingless. These insects pass the pupal stage in the ground, and reach the boughs to lay their eggs by crawling up the trunks of the trees. To check them, "grease-banding" round the trees has been adopted; but as many other pests eat the leafage, it is best to kill all at once by spraying with arsenical poisons. Among other notable Lepidopterous pests are the "surface larvæ" or Cutworms (*Agrotis spp.*), the caterpillars of various Noctuæ; the Codling Moth (*Carpocapsa pomonella*), which causes the maggot in apples, has now become a universal pest, having spread from Europe to America and to most of the British Colonies. In many years quite half the apple crop is lost in England owing to the larvæ destroying the fruit. Sugar canes suffer from the Sugar-cane Borer (*Diatioca sacchari*) in the West Indies; tobacco from the larvæ of Hawk Moths (*Sphingidæ*) in America; corn and grass from various Lepidopterous pests all over the world. Nor are stored goods exempt, for much loss annually takes place in corn and flour from the presence of the larvæ of the Mediterranean Flour Moth (*Ephestia kuniella*); while furs and clothes are often ruined by the Clothes Moth (*Tinea trapezella*).

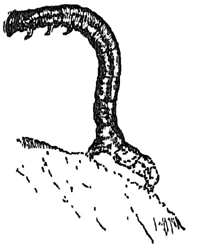

FIG. 3.—Looper-larva of Winter Moth (*Cheimatobia brumata*).

By far the most destructive insects in warm climates belong to the Hemiptera, especially to the *Coccidæ* or Scale Insects. All fruit and forest trees suffer from these curious insects, which in the female sex always remain apterous and apodal and live attached to the bark, leaf, and fruit, hidden beneath variously-formed scale-like coverings. The male scales differ in form from the female; the adult male is winged, and is rarely seen. The female lays her eggs beneath the scaly covering, from which hatch out little active six-legged larvæ, which wander about and soon begin to form a new scale. The *Coccidæ* can, and mainly do, breed asexually (parthenogenetically). One of the most important is the San José Scale (*Aspidiotus perniciosus*), which in warm climates attacks all fruit and many other trees, which, if unmolested, it will soon kill (Fig. 4). These scales breed very rapidly; Howard states one may give rise to a progeny of 3,216,080,400 in one year. Other scale insects of note are the cosmopolitan Mussel Scale (*Mytilaspis pomorum*) and the Australian *Icerya purchasi*. The former attacks apple and pear; the latter, which selects orange and citron, was introduced into America from Australia, and carried ruin before it in some orange districts until its natural enemy, the lady-bird beetle, *Adalia cardinalis*, was also imported.

After the *Coccidæ* the next most important insects economically are the Plant Lice or *Aphididæ*. These breed with great rapidity under favourable conditions: one by the end of the year will be accountable, according to Linnæus, for the enormous number of a quintillion of its species. Aphides are born, as a rule, alive, and the young soon commence to reproduce again. Their food consists mainly of the sap obtained from the leaves and blossom of plants, but some also live on the roots of plants (*Phylloxera vastatrix* and *Schizoneura lanigera*). Aphides often ruin whole crops of fruit, corn, hops, &c., by sucking out the sap, and not only check growth, but may even entail the death of the plant. Reproduction is mainly asexual,

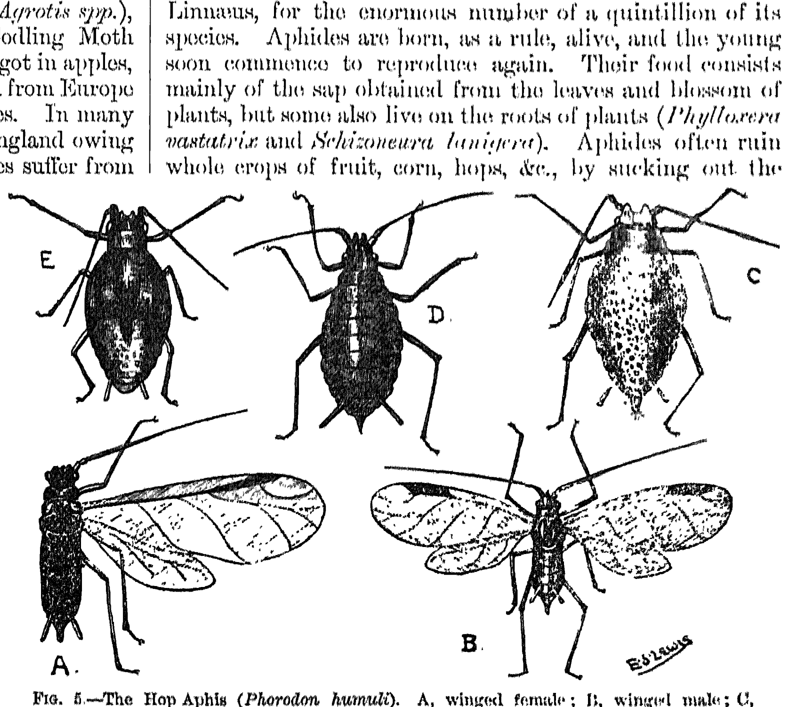

FIG. 5.—The Hop Aphis (*Phorodon humuli*). A, winged female; B, winged male; C, ovigerous wingless female; D, viviparous wingless female from plum; E, pupal stage.

the females producing living young without the agency of a male. Males in nearly all species appear once a year, when the last female generation, the ovigerous generation, is fertilized, and a few large ova are produced to carry on the continuity of the species over the winter. Some aphides live only on one species of plant, others on two or more plants. An example of the latter is seen in the Hop Aphis (*Phorodon humuli*), which passes the winter and lives on the sloe and damson in the egg stage until the middle of May or later, and then flies off to the hops, where it causes endless harm all the summer (Fig. 5); it flies back to the prunes to lay its eggs when the hops are ripe. Another Aphis of importance is the Woolly Aphis (*Schizoneura lanigera*) of the apple and pear: it secretes tufts of white flocculent wool often to be seen hanging in patches from old apple trees, where the insects live in the rough bark and form cankered growths both above and below ground. Aphides are provided with a mealy skin, which does not allow water to be attached to it, and thus insecticides for destroying them contain soft soap, which fixes the solution to the skin; paraffin is added to corrode the skin, and the soft soap blocks up the breathing pores and so produces asphyxiation.

Amongst *Orthoptera* we find many noxious insects, notably the Locusts, which travel in vast cloud-like armies, clearing the whole country before them of all vegetable life. The most destructive locust is the migratory locust (*Locusta migratoria*), which causes wholesale destruction in the East. Large pits are dug across the line of advance of these great insect armies to stop them when in the larval or wingless stage, and even huge bonfires are lighted to check their flight when adult. So dense are these "locust clouds" that they sometimes quite darken the air. The commonest and most widely distributed migratory locust is *Pachytylus cinerascens*. The mole cricket (*Gryllotalpa vulgaris*) and various cockroaches (*Blattidæ*) are also amongst the pests found in this order.

Of *Neuroptera* there are but few injurious species, and many, such as the lace wing flies (*Hemerobiidæ*), are beneficial.

*The Treatment of Insect Pests.*—One of the most important ways of keeping insect pests in check is by "spraying" or "washing." This method has made great advances in recent years. All the pioneer work has been done in America; in fact, until the South-Eastern Agricultural College undertook the elucidation of this subject, little was known of it in England except by a few growers. The results and history of this essential method of treatment are embodied in Professor Lodemann's work on the *Spraying of Plants*, 1896. In this treatment we have to bear in mind what the entomologist teaches us, that is, the nature, habits, and structure of the pest.

For insects provided with a biting mouth, which take nourishment from the whole leaf, shoot, or fruit, the poisonous washes used are chiefly arsenical. The two most useful arsenical sprays are Paris green and arsenate of lead. To make the former, mix 1 oz. of the Paris green with 15 gallons of soft water, and add 2 oz. of lime and a small quantity of agricultural treacle; the latter is prepared by dissolving 3 oz. of acetate of lead in a little water, then 1 oz. of arsenate of soda in water and mixing the two well together, and adding the whole to 16 gallons of soft water; to this is added a small quantity of coarse treacle. For piercing-mouthed pests like *Aphides* no wash is of use unless it contains a basis of soft soap. This soft-soap wash kills by contact, and may be prepared in the following way:—Dissolve 6 to 8 ℔ of the best soft soap in boiling soft water, and while still hot (but of course taken off the fire) add 1 gallon of paraffin oil and churn well together with a force-pump; the whole may then be mixed with 100 gallons of soft water. The oil readily separates from the water, and thus a perfect emulsion is not obtained; this difficulty has been solved by Mr Cousin's paraffin naphthalene wash, which is patented, but can be made for private use. It is prepared as follows:—Soft soap, 6 ℔ dissolved in 1 quart of water; naphthalene, 10 oz. mixed with 1½ pint of paraffin; the whole is mixed together. When required for use, 1 ℔ of the compound is dissolved in 5 to 10 gallons of warm water.

These two washes are essential to the well-being of every orchard in all climates. Not only can we now destroy larval and adult insects, but we can also attack them in the egg stage by the use of a caustic alkali wash during the winter; besides destroying the eggs of such pests as the *Psyllidæ*, Red Spider, and some Aphides, this also removes the vegetal encumbrances which shelter numerous other insect pests during the cold part of the year. Caustic alkali wash is prepared by dissolving 1 ℔ of crude potash and 1 ℔ of caustic soda in soft water, mixing the two solutions together, adding to them ¾ ℔ of soft soap, and diluting with 10 gallons of soft water when required for use. Another approved insecticide for Scale Insects is resin wash, which acts in two ways: first, corroding the soft scales, and second, fixing the harder scales to stop the egress of the hexapod larvæ. It is prepared as follows:—First crush 8 ℔ of resin in a sack, and then place the resin in warm water and boil in a cauldron until thoroughly dissolved; then melt 10 ℔ of caustic soda in enough warm water to keep it liquid, and mix with the dissolved resin; keep stirring until the mixture assumes a clear coffee-colour, and for ten minutes afterwards; then add enough warm water to bring the whole up to 25 gallons, and well stir. Bottle this off, and when required for use dilute with three times its bulk of warm soft water, and spray over the trees in the early spring just before the buds burst. For mites (*Acari*) sulphur is the essential ingredient of a spray. Liver of sulphur has been found to be the best form, especially when mixed with a paraffin emulsion. Bud Mites (*Phytoptidæ*, Fig. 6) are of course not affected. Sulphur wash is

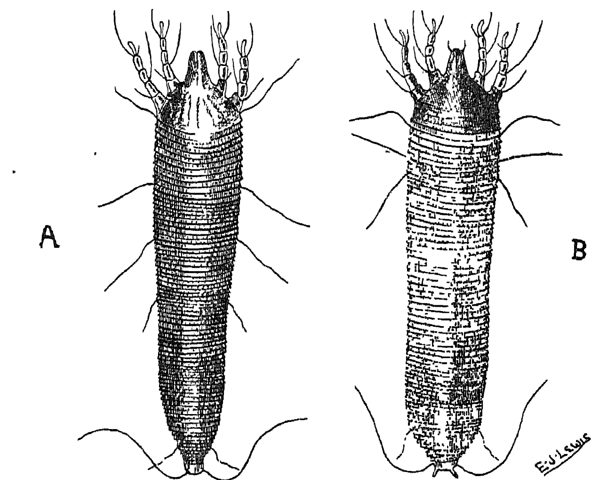

FIG. 6.—Bud Mites (*Phytoptidæ*). A, currant bud mite (*Phytoptus ribis*); B, nut bud mite (*P. avellanæ*).

made by adding to every 10 gallons of warm paraffin emulsion or paraffin-naphthalene-emulsion 7 oz. of liver of sulphur, and stirring until the sulphur is well mixed. This is applied as an ordinary spray. Nursery stock should always be treated, to kill scale, aphis, and other pests which it may carry, by the gas treatment, particularly in the case of stock imported from a foreign climate. This treatment, both out of doors and under glass, is carried out as follows:—Cover the plants in bulk with a light gas-tight cloth, or put them in a special fumigating house, and then place 1 oz. of cyanide of potassium in lumps in a dish with water beneath the covering, and then pour 1 oz. of sulphuric acid over it (being careful not to inhale the poisonous fumes) for every 1000 cubic feet of space beneath the cover. The gas generated, hydrocyanic acid should be left to work for at least an hour before the stock is removed, when all forms of animal life will be destroyed.

For spraying, proper instruments must be used, by means of which the liquid is sent out over the plants in as fine a mist as possible. Numerous pumps and nozzles are now made by which this end is attained. Both horse and hand machines are employed, the former for hops and large orchards, the latter for bush fruit and gardens. In America, where trees in parks as well as orchards and gardens are treated, steam-power is sometimes used. Among the most important sprayers are the Strawson horse sprayers and the smaller Eclair and Notus knapsack pumps, carried on the back (Fig. 7). The nozzles for "mistifying" the wash most in use are known as the Vermorel and Riley's, which can be fitted to any length of tubing, so as to reach any height, and can be turned in any direction. The pumps in the machine keep the insecticide constantly mixed, and at the same time force the wash with great strength through the nozzle, and so to the exterior, as a fine mist; every part of the plant is thus affected.

*Beneficial Insects* have also to be considered in Economic Entomology. They are of two kinds—(1) those that help to keep down an excess of other insects by acting either

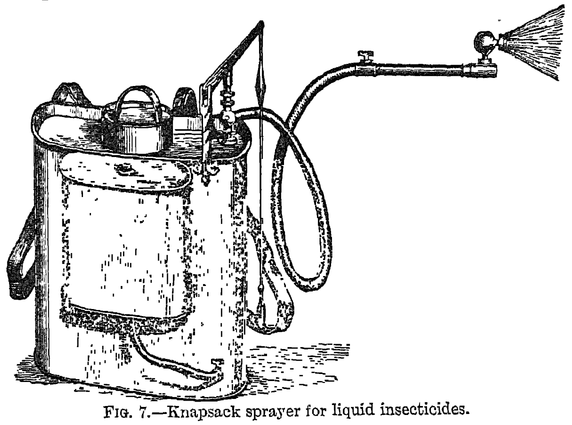

FIG. 7.—Knapsack sprayer for liquid insecticides.

as parasites or by being insectivorous in habit; and (2) insects of economic value, such as the bee and silkworm. Amongst the most important friends to the farmer and gardener are the Hymenopterous families of Ichneumon Flies (*Ichneumonidæ* and *Braconidæ*); the Dipterous families *Syrphidæ* and *Tachinidæ;* the Coleopterous families *Coccinellidæ* and *Carabidæ;* and the Neuropterous *Hemerobiidæ*, or Lace-Wing Flies. Ichneumon Flies lay their eggs either in the larvæ or ova of other insects, and the parasites destroy their host. In this way the Hessian Fly is doubtless kept in check in Europe, and the Aphides meet with serious hindrance to their increase. If a number of plant-lice are examined, a few will be found looking like little pearls; these are the dried skins of those that have been killed by *Ichneumonidæ*. The *Syrphidæ*, or Hover Flies, are almost exclusively aphis-feeders in their larval stage. *Tachina* flies attack lepidopterous larvæ. One of the most notable examples of the use of insect allies is the case of the Australian Lady Bird, *Adalia cardinalis*, which, in common with all lady birds, feeds off *Aphidæ* and *Coccidæ*. The Icerya Scale (*Icerya purchasi*) imported into America ruined the orange groves, but its enemy, the *Adalia*, was also imported from Australia, and counteracted its abnormal increase with such great results that the crippled orange groves are now once more profitable. (F. V. T.)

# ECONOMICS.

In a former article (see POLITICAL ECONOMY, *Ency. Brit.*, 9th edition, vol. xix. pp. 346–401), in which the growth of Economics from the earliest times was described, it was shown that, owing partly to the conditions affecting the industrial and commercial organization and the economic policy of different countries, partly to the influence on economics of the growth of other sciences, there were in Europe and America various schools of economists representing somewhat different views as to the aims, the subject-matter, and the method of the science. This state of things was no doubt a symptom of vitality and progress, but it was associated with much destructive criticism of principles hitherto considered well founded, and diminished for a time both the practical usefulness of the science and the estimation in which it was held by ordinary men. During the last few years there have been no new departures of fundamental importance, such as the application of the historical method to economic investigation; the methods characteristic of the different groups of economists have been seen to be not mutually exclusive, but complementary to each other; and much of the work done has been constructive, in the sense that economic writers have devoted themselves to the solution of particular problems rather than the discussion of the method by which the problems should be attacked. The time has therefore now arrived when we can review the situation and attempt to combine the positive results of a period of active criticism and inquiry. Many years must elapse before we can survey the whole field of economic investigation, if indeed the time ever arrives when we can undertake so great a task. Present tendencies scarcely point to the creation of a complete and well-rounded system of economics such as appealed to past generations. Like the world of business and commerce of which it is the reflex, economic thought resembles a great river. Its sources lie far back in the historic past. Its course has been determined by practical needs which are no longer felt, by ideals to which the present generation does not respond, and by systems of politics and philosophy whose day is over. The titles of an economic bibliography are a brief epitome of general history, and a complete survey of economic thought at the present time would involve a careful examination of many of the important questions which now occupy the public mind in, at least, Europe and America. It is the spirit and the method of economic science which we may hope will be permanent. The more numerous the points of contact between economic science and the real world of business, the less possible will it be, at any rate for many years, to construct a complete system. In the present state of economic knowledge, generality can only be obtained by abstraction. But it is possible to describe the character and and subject-matter of economics, to indicate its relation to other sciences, to explain the methods by which economists reach their conclusions, to show within what limits a science which we may call General Economics is possible, to apply our reasoning to particular groups of practical questions; and that is the task we shall attempt in the following pages.

***A review of recent work on economics.***

***Definition.***

Economics, as we understand it, is the science which investigates the manner in which nations or other larger or smaller communities, and their individual members, obtain food, clothing, shelter, and whatever else is considered desirable or necessary for the maintenance and improvement of the conditions of life. It is thus the study of the life of communities with special reference to one side of their activity. It necessarily involves the scientific examination of the structure and organization of the community or communities in question; their history, their customs, laws, and institutions; and the relations between their members, in so far as they affect or are affected by this department of their activity. At the root of all economic investigation lies the conception of the standard of life of the community. By this expression we do not mean an ideal mode of living, but the habits and requirements of life generally current in a community or grade of society at a given period. The standard of life of the ordinary well-to-do middle class in England, for example, includes not only food, clothing, and shelter of a kind different in many respects from that of a similar class in other countries and of other classes in England, but a highly complicated mechanism, both public and private, for ministering to these primary needs, habits of social intercourse, educational and sanitary organization, recreative arrangements, and many other

elements. Many influences operating for a long period of time on the character and the environment of a class go to determine its standard of life. In a modern industrial community it is possible to express this standard fairly accurately for the purposes of economic investigation in terms of money. But it is doubtful whether the most complete investigation would ever enable us to include all the elements of the standard of life in a money estimate. The character, tastes, and capacity for management of different individuals and groups differ so widely that equal incomes do not necessarily imply identity of standard. In the investigation of past times, the incommensurate elements of well-being are so numerous that merely money estimates are frequently misleading. The conception of the standard of life involves also some estimate of the efforts and sacrifices people are prepared to make to obtain it; of their ideals and character; of the relative strength of the different motives which usually determine their conduct. But no carefully devised calculus can take the place of insight, observation, and experience. The economist should be a man of wide sympathies and practical sagacity, in close touch with men of different grades, and, if possible, experienced in affairs.

**Character of subject-matter.**

It is evident that no permanent classification is possible of what is or is not of economic significance. No general rules, applicable to all times, can be laid down as to what phenomena must be examined or what may be neglected in economic inquiry. The different departments of human activity are organically connected, and all facts relating to the life of a community have a near or remote economic significance. For short historical periods, indeed, many phenomena are so remotely connected with the ordinary business of life that we may ignore them. But at any moment special causes may bring into the field of economic inquiry whole departments of life which have hitherto been legitimately ignored. In times past, biblical exegesis, religious ideals, and ecclesiastical organization, the purely political aims of statesmen, chance combinations of party politics and the intrigues of diplomatists, class prejudice, social conventions, apparently sudden changes of economic policy, capricious changes of fashion—all these causes and many others have exerted a direct and immediate influence on the economic life of the community. In our own day we have had many illustrations of the manner in which special circumstances may at once bring an almost unnoticed series of scientific investigations into direct and vital relation with the business world. The economist must, therefore, not only be prepared to take account of the physical features of the world, the general structure and organization of the industry and commerce of different states, the character of their administration, and other important causes of economic change. He must be in touch with the actual life of the community he is studying, and cultivate "that openness and alertness of the mind, that sensitiveness of the judgment, which can rapidly grasp the significance of at first sight unrelated discoveries or events."

Some people are of opinion that the factors to be taken account of in economic investigation are so numerous that progress on these lines is impossible. It would certainly be impossible if we had to begin *de novo* to construct the whole fabric of economic science. But, as we shall see, it is no more necessary to do this in the world of science than it is in the world of business or politics. There is in existence a vast store of accumulated knowledge, and few, if any, departments of economics have been left quite unilluminated by the researches of former generations. Progress is the result of adaptation rather than reconstruction. It must be remembered also that economic work in modern times is carried on by consciously or unconsciously associated effort, and although it must always require high qualities of judgment, capacity, and energy, many of the difficulties which at first sight appear so insuperable give way when they are attacked. In some ways also the study of highly developed organizations like the modern industrial state is simpler than that of earlier forms of society.

**Ancient and modern conditions in England.**

In the earliest times for which we have abundant material the economic life of England had already reached in certain directions a high degree of complexity. Even in the rural districts, manorial records reveal the existence of a great variety of classes and groups of persons engaged in the performance of economic functions. The lord of the manor with his officials and retainers, the peasantry bound to him by ties of personal dependence and mutual rights and obligations, constituted a little world, in which we can watch the play of motives and passions not so dissimilar as we are sometimes led to believe from those of the great modern world. In many a country district the gradations of social rank were more continuous, the opportunities of intercourse more frequent, and the capacity for organization greater than in modern times. The manorial accounts were kept with precision and detail, and we are told that a skilled official could estimate to the utmost farthing the value of the services due from the villein to his lord. The manor was indeed self-sufficient and independent in the sense that it could furnish everything required by the majority of the inhabitants, and that over the greater part of rural England production was not carried on with a view to a distant market. But in the earliest times the manor was subjected to external influences of great importance. Vast areas of the country were in fact under the single control of a territorial lord or an ecclesiastical foundation. Every manor composing these great fiefs was likely to be affected by the policy or the character of the administration of the feudal lord, and he, again, by the policy or the difficulties, the strength or the weakness, of the central government. Foreign trade and foreign intercourse were undeveloped, but their influence was in historical times never entirely absent, while the influence of Roman law and the Christian Church constantly tended to modify the manorial organization. In the towns the division of labour had proceeded much further than in the rural districts, and there were in existence organized bodies, such as the Gild Merchant and the crafts, whose functions were primarily economic. But one of the most striking characteristics of town life in the Middle Ages was the manner in which municipal and industrial privileges and responsibilities were interwoven. In modern times the artisan, however well trained, efficient, and painstaking he may be, does not, in virtue of these qualities, enjoy any municipal or political privileges. By means of his trade union, co-operative society, or club he may gain some experience in the management of men and business, and in so far as the want of a sufficient income does not constitute an insuperable difficulty, he may share in the public life of the country. But in his character as artisan he enjoys no municipal or political privileges. In the Middle Ages this differentiation of the industrial, municipal, and political life had not taken place, and in order to understand the working of at first sight purely economic regulations it is necessary to make a close study of the functions of local government. But this, after all, does not carry us very far. From the very nature of the records in which we study the town life of the Middle Ages, it follows that we obtain from them only a one-sided view. No one knows what proportion of the industrial population was included in the organized guilds,

or how complete was the control exercised by these bodies over their members. Elaborate regulations were in force, but no one knows how elastic they were in practice. Mediæval Englishmen were particularly apt to put their aspirations into a legal form, and then rest satisfied with their achievement. The number of regulations is scarcely to be regarded as a test of their administrative success. Further, as the country became more consolidated and the central government extended its authority over economic affairs, new regulations came into force, new organs of government appeared, which were sometimes in conflict, sometimes in harmony, with the existing system, and it becomes for a time far more difficult to obtain a clear view of the actual working of economic institutions. Thus the study of the economic life of the Middle Ages is one of the most complicated subjects which can engage the attention of man. It is impossible to carry the process of isolation very far. The different threads of social activity are so closely interwoven that we cannot follow any one for very long without forming wrong impressions, and it becomes necessary to turn back and study others which seemed at first sight unrelated to the subject of our investigations. Under an apparently uniform and stable system of social regulation there was much variation and movement, the significance of which it is impossible to estimate. Materials for forming such an estimate no doubt exist, but before doing so we have to study in infinite detail a vast number of separate manors, municipalities, or other separate economic areas. This involves great industry on the part of many scientific workers. Meanwhile we can *illustrate* the economic life of the Middle Ages, describe its main features, indicate the more important measures of public policy, and draw attention to some of the main lines of development.

***Conditions of economic science.***

It is only as we approach more modern times that the conditions of economic study are realized and economic science, as we understand it, becomes possible. Those conditions are: (i.) the life of the state or other community or communities we are studying must be so differentiated that we can isolate those functions which are wholly or predominantly economic. The "separation of employments" is not only a condition of economic efficiency; it was necessary before we could have an economic science. (ii.) We must be in a position so far to understand and estimate the character and motives of different classes and groups in these communities that we can rightly interpret their action. This condition cannot be realized without great difficulty, for "economic motives" are very different in different periods, nations, and classes, and even for short periods of time in the same country are modified by the influence of other motives of an entirely different order. In studying the economic history of the 18th century, for example, it is not enough to assume with Defoe that "gain is the design of merchandise." We have to be saturated, as it were, with 18th-century influences, so that we can realize the conditions in which industry and trade were carried on, before we can rightly explain the course of development. In our own day labour disputes, to take another example, can scarcely ever be resolved into a question of merely pecuniary gain or loss. The significance of the amount of money involved varies greatly for different trades, and can only be understood by reference to the character and habits of the people concerned. But questions of sentiment, shop-feeling, and trade customs invariably play an important part. (iii.) Economics can never lead to anything but hypothetical results unless we not only realize that we must "take account of" other than the purely economic factors, but also give due weight and significance to these factors. No explanation of the industrial situation in Germany, for example, would be intelligible or satisfactory even from the economic point of view which ignored the significance of the political conditions which Germans have to deal with. So, again, it is impossible to make a useful comparative estimate of the advantages and disadvantages of the transport systems of England, the United States, and Germany, unless we keep constantly in view the very different geographical, military, and political conditions which these systems have to satisfy. (iv.) Sufficient information must be available to enable us to test the validity of our hypotheses and conclusions. Whatever "method" of economic investigation we employ, we must at every stage see how far our reasoning is borne out by the actual experience of life. This obvious condition of scientific inquiry is very far from being completely realized even at the present time. It implies the existence of a well-trained class engaged in the work of collecting information, and much organization both by the state and private bodies. These four conditions can be reduced to two. The community we are studying must have reached such a stage of development that its economic functions and those immediately cognate to them form a well-defined group, and adequate means must be available so that we can, as it were, watch the performance of these functions and test our hypotheses and conclusions by observation and experience.

It is easy to understand, therefore, why we trace the beginnings of economics, so far as England is concerned, in the 16th century, and why the application of strict scientific tests in this subject of human study has become possible only in comparatively recent times. Mediæval economics was little more than a casuistical system of elaborate and somewhat artificial rules of conduct. From the close of the Middle Ages until the middle of the 18th century thousands of pamphlets and other works on economic questions were published, but, with the few notable exceptions mentioned in the former article, the vast majority of the writers have little or no scientific importance. Their works frequently contain information given nowhere else, and throw much light on the state of opinion in the age in which they wrote. It is also possible to find in them many anticipations of the views of the economists of later times; but such statements were as a rule generated merely by the heat of controversy on some measure or event of practical importance, and when the controversy died down were seldom regarded or incorporated in a scientific system. Trade bias, personal impressions, and guess-work took the place of scientific method. This was inevitable in the absence of trustworthy information on an adequate scale, and from the immediately practical aims of the writers. But from the end of the 17th century economics has been definitely recognized as a subject of scientific study.

***Necessity of economic science.***

In modern times the conditions which have made economic science possible have also made it necessary. While it is impossible to give a strictly economic interpretation of the earlier history of nations, economic interests so govern the life and determine the policy of modern states that other forces, like those of religion and politics, seem to play only a subsidiary part, modifying here and there the view which is taken of particular questions, but not changing in any important degree the general course of their development. This may be, in the historical sense, merely a passing phase of human progress, due to the rapid extension of the industrial revolution to all the civilized and many of the uncivilized nations of the world, bringing in its train the consolidation of large areas, a similarity of conditions within them, and amongst peoples and governments a great increase in the strength

of economic motives. When the world has settled down to the new conditions, if it ever does so, we may be confronted with problems similar to those which our forefathers had to solve. But, for the time, if we know the economic interests of nations, classes, and individuals, we can tell with more accuracy than ever before how in the long run they will act. Public policy therefore requires the closest possible study of the economic forces which are moulding the destinies of the great nations of the world. In most civilized countries except England this is recognized, and adequate provision is made for the study of economic science. But the subject is not only of immediate concern to the state in its corporate and public capacity. The neglect of it in the domain of private business can now only lead to disastrous results. To quote from a recently published work (see *National Education: a Symposium*, 1901), "the commercial supremacy of England was due to a variety of causes, of which superior intelligence, in the ordinary business sense, was not the most important. Her insular position, continuity of political development, and freedom from domestic broils played an important part in bringing about a steady and continuous growth of industry and manufactures for several generations before the modern era. The great wars of the 18th and the beginning of the 19th century, which arrested the growth of continental nations, gave England the control of the markets of the world. When peace was restored, England enjoyed something in the nature of a monopoly. The competition of France ceased for a time to be an important factor. What is now the German Empire was a mere congeries of small states, waging perpetual tariff wars upon each other. In the old Prussian provinces alone there were fifty-three different customs frontiers, and German manufactures could not develop until the growth of the Zollverein brought with it commercial consolidation, internal freedom, and greater homogeneity of economic conditions. The industries of the United States were in their infancy. Thus the productive power of England was unrivalled, and her manufactures and business men, under a régime rapidly approximating to complete freedom of trade, could reap the full advantages to be derived from the possession of great national resources and production by machinery. Commercial supremacy required not so much highly trained intelligence amongst manufacturers and merchants as keen business instinct and a certain rude energy. In the last generation all that has changed, and the change is of a permanent character. The struggle of the future must inevitably be between a number of great nations, more or less equally well equipped, carrying on production by the same general methods, each one trying to strengthen its industrial and commercial position by the adoption of the most highly developed machinery, and all the methods suggested by scientific research, policy, or experience. Under these conditions, it is no longer possible for the individual merchant, or for small groups of merchants, to acquaint themselves, by personal experience alone, with more than a fractional part of the causes which affect the business in which they are engaged. The spread of the modern industrial system has brought with it the modern state, with its millions of consumers, its vast area, its innumerable activities, its complicated code of industrial and commercial law. At the same time, the revolution in the means of transport and communication has destroyed, or is tending to destroy, local markets, and closely interwoven all the business of the world. Events in the most distant countries, industrial and commercial movements at first sight unrelated to the concerns of the individual merchant, now exert a direct and immediate influence upon his interests. The technical training of the factory or the office, the experience of business, the discharge of practical duties, necessary as they are, do not infallibly open the mind to the large issues of the modern business world, and can never confer the detailed acquaintance with facts and principles which lie outside the daily routine of the individual, but are none the less of vital importance." Economics, therefore, under modern conditions, is not only a subject which may usefully occupy the attention of a leisured class of scientific men. It should form part of the training of educated men of all classes, on grounds of public policy and administrative and business efficiency.

***Relations between economics and other sciences.***

The relations between economics and other sciences cannot be stated in a very general form. They vary for different periods, and are not the same for all branches of economics. There is no subject of human study which may not be at some time or other of economic significance, and anything which affects the character, the ideals, or the environment of man may make it necessary to modify our assumptions and our reasoning with regard to his conduct in economic affairs. But if the economist, while studying one side of man's activities, must also cultivate all other branches of human learning, it is obvious that no substantial progress can be made. The economist frankly assumes the reality of the existing world and takes men as they are, or as they have been if he is studying past times. His assumptions are based upon ordinary observation and experience, and are usually accurate in proportion to his practical shrewdness and sagacity, so that he is not interested in the speculative flights of philosophy, except in so far as they influence or have influenced conduct. In times past, and to a less extent in our own day, philosophical conceptions have formed the basis of great systems of politics and economics. The historical relations between philosophy and economics are of great importance in tracing the development of the latter, and have done much to determine its present form. But the modern conception of society or the state owes more to biology than philosophy, and actual research has destroyed more frequently than it has justified the assumptions of the older philosophical school. Experimental psychology may in course of time have an important bearing on economics, but the older science cannot be said to be of much significance except in its historical aspects. Ethics is in much the same position. That is, it is possible to conceive of an ethical science which would extend considerably our knowledge of economic affairs, but no important new principle or original discovery, relevant to economic investigation, has come from that quarter in recent years, and at present ethics has more to learn from economics than the latter has from ethics. It is in the adaptation of biological conceptions and methods, in the positive contributions of jurisprudence, law, and history, in the rigorous application, where possible, of quantitative tests, that the explanation of the present position of economics is to be found. Mathematics has influenced the form and the terminology of the science, and has sometimes been useful in analysis, but mathematical methods of reasoning, in their application to economics, while possessing a certain fascination, are of very doubtful utility.

There is no method of investigation which is peculiarly economic or of which economics has the monopoly. In every age economists have applied the methods ordinarily in use amongst scientific men. There would probably have been no controversy at all on this subject but for the fact that economics was elaborated into systematic form, and made the basis of practical measures of the greatest importance, long before the remarkable development in

the 19th century of historical research, experimental science, and biology. The application of the *à priori* method in economics was an accident, due to its association with other subjects and the general backwardness of other sciences rather than any exceptional and peculiar character in the subject-matter of the science itself. The methods applied to economics in the 18th and the early part of the 19th century were no more invented with a special view to that subject than the principles of early railway legislation, in the domain of practical policy, were devised with a special view to what was then a new means of transport. As a matter of fact, discussions of method and the criticism of hypotheses and assumptions are very rarely found in early economic works. It is only by reference to the prevailing ideas in philosophy and politics that we can discover what was in the minds of their authors. The growth of a science is much like the growth of a constitution. It proceeds by adaptation and precedent. The scientific and historical movement of the 19th century was revolutionary in character. When it began to affect economics, many people were afraid that the whole fabric of the science would be destroyed and the practical gains it had achieved jeopardized. These fears were justified, in so far as those who entertained them shut their eyes to everything new and assumed an attitude of no compromise. Where the newer methods were assimilated, the position of economics was strengthened and its practical utility increased. General discussion of method, however, is rarely profitable. In all branches of economics, even in what is called the pure theory, there is an implied reference to certain historical or existing conditions of a more or less definite character; to the established order of an organized state or other community, at a stage of development which in its main features can be recognized. In all economic investigation assumptions must be made, but we must see that they are legitimate in view of the actual life and character of the community or communities which are the subject of investigation. In common with other sciences, economics makes use of "abstractions"; but if for some problems we employ symbolic processes of reasoning, we must keep clearly in view the limits of their significance, and neither endow the symbols with attributes they can never possess, nor lose sight of the realities behind them. Every hypothesis must be tested by an appeal to the facts of life, and modified or abandoned if it will not bear examination, unless we are convinced on genuine evidence that it may for a time be employed as a useful approximation, without prejudice to the later stages of the investigation we are conducting.

***Method of economic investigation.***

We shall best illustrate the character and method of economic reasoning by examples, and for that purpose let us take first of all a purely historical problem, namely, the effect on the wage-earners of the wages clauses of the Statute of Apprenticeship (1563). It is at once obvious that we are dealing not with an abstract scheme of regulation in a hypothetical world, but with an Act of Parliament nominally in force for two hundred and fifty years, and applicable to a great variety of trades whose organization and history can be ascertained. The conclusions we reach may or may not modify any opinions we have formed as to the manner in which wages are determined under modern conditions. For the time being such opinions are irrelevant to the question we are investigating, and the less they are in our minds the better. There is no reason why we should apply to this particular Act a different method of inquiry from that we should apply to any other of the numerous Acts, of more or less economic importance, passed in the same session of Parliament. The first step is to see whether there is a *primâ facie* case for inquiry, for many Acts of Parliament have been passed which have never come into operation at all, or have been administered only for a short time on too limited a scale to have important or lasting results. The justices were authorized to fix wages at the Easter Quarter Sessions. Did they exercise their powers? To answer this question we must collect the wages assessments sanctioned by the magistrates. This is a perfectly simple and straightforward operation, involving nothing more than familiarity with records and industry in going through them. Without having recourse to any elaborate process of economic reasoning, by confining our attention to one simple question, namely, what happened, we can establish conclusions of the greatest interest to economic historians and, further, define the problem we have to investigate. We can show, for example: (1) that the Statute of Apprenticeship did not stand alone; it was one of a long series of similar measures, beginning more than two centuries before, which in their turn join on to the municipal and gild regulations of the Middle Ages; one of an important group of statutes, more or less closely interwoven throughout their history, administered by local authorities whose functions had grown largely in connexion with this legislation and the gradual differentiation of the trades and callings to which it related. (2) That wages were regulated with much greater frequency during the reigns of Elizabeth, James I., and Charles I. than at any later period. (3) That they were regulated in some counties and not in others. (4) That in the counties and towns where they were regulated the action of the magistrates was in general spasmodic, and rarely continuous for a long series of years. (5) That the magistrates used their powers sometimes to raise wages, sometimes to force them down. (6) That the local variations of wages and prices were what we should call excessive, so that the standard of comfort in one district was very different from that of others. (7) That the wages assessments group themselves round certain short periods, coincident in many instances with high prices, increase of poverty, and other causes of exceptional action. (8) That what we may call, with the above limitations, the effective period of the Act terminates with the outbreak of the Civil War. (9) That subsequent to that period organic changes in the industries affected, coupled with the incompetence of Parliament to adapt the old legislation to new conditions, and the growing acceptance of the doctrine of *laisser faire*, brought about a general disuse of the statute, though isolated attempts to enforce it were made and new Acts applicable to certain trades were passed in the 18th century. (10) For more than one hundred years before the repeal of the Act, trade unions and other forms of voluntary association amongst wage-earners, combinations amongst employers, collective agreements, customary regulations, were established in many of the important trades of the country. But these conclusions, after all, suggest more difficulties than they remove, for they show that our inquiry, instead of presenting certain well-marked features which can be readily dealt with, has to be split up into a number of highly specialized studies: the investigation of rates of wages, prices, and the standard of comfort in different localities, bye-industries, regularity of employment, the organization of particular trades, the economic functions of local authorities, apprenticeship, and a host of other subjects. Moreover, all these subjects hang together, so that it seems impossible to come to a decision about one of them without knowing all about the others.

***An illustration of economic method.***

It is a comparatively simple thing to state the questions to which we want an answer, but extremely difficult to define the exact nature of the evidence which will constitute a good answer; easy enough to say we must try

hypothesis after hypothesis, and test each one by an appeal to the facts, but a man may easily spend his life in this sort of thing and still leave to his descendants nothing more than a legacy of rejected hypotheses. Every volume of records we look through contains a mass of detailed information on the economic life of England in the period we are studying. How much of it is relevant to the subject of inquiry? What is to be the principle of selection? How shall we determine the relative weight and importance of different kinds of relevant evidence? As in modern problems, so in those of past times, a man requires for success qualities quite distinct from those conferred by merely academic training and the use of scientific methods. A correct sense of proportion and the faculty of seizing upon the dominant factors in an historical problem are the result partly of the possession of certain natural gifts in which many individuals and some nations are conspicuously wanting, partly of general knowledge of the working of the economic and political institutions of the period we are studying, partly of what takes the place of practical experience in relation to modern problems, namely, detailed acquaintance with different kinds of original sources and the historical imagination by which we can realize the life and the ideals of past generations. These qualities are required all the more because, in order to make any further progress with such an inquiry as we have suggested, we have deliberately to make use of abstraction as an instrument of investigation.

***The plan of a general theory.***

Let us see how this will work out. Suppose we have selected one of the numerous subsidiary problems suggested by the general inquiry, and obtained such full and complete information about one particular industry that we can tabulate the wages of the workers for a long series of years. We may do the same for other industries, some of them coming under the Statute of Apprenticeship, others not. If all the industries belong to one economic area over which, so far as we can tell from general statistics of wages and prices, and other information, fairly homogeneous conditions prevailed, we may be able to reach some useful conclusions as to the operation of the Act. But it would be absurd to suppose that we could reach those conclusions by simple reference to the trades themselves. We cannot assume that the fluctuations in wages were due to the action or inaction of magistrates without the most careful examination of the other influences affecting the trades. In economic affairs the argument *post hoc propter hoc* never leads to the whole truth, and is frequently quite misleading. We cannot suppose that the policy of the Merchant Adventurers' Company had nothing to do with the woollen industry; that the export trade in woollen cloth was quite independent of the foreign exchanges and international trade relations in those times; that the effect on wages of the state of the currency, the influx of new silver, the character of the harvests, and many other influences can be conveniently ignored. In studying, therefore, such an apparently simple question as the effect of an Act of Parliament on wages in a small group of trades we want a general theory which we can use as a kind of index of the factors we have to consider.

***Difficulties due to want of evidence.***

We shall return to this subject later (see p. 646). It is sufficient to say here that all that we require is amply provided by readily-accessible works on economics. Assuming that we have in our minds this safeguard against loose thinking and neglect of important factors, the investigation of the special problems arising out of the general inquiry resolves itself into a careful definition of each problem we wish to deal with, and the collection, tabulation, and interpretation of the evidence. In most cases the interpretation of the facts is far from obvious, and we have to try several hypotheses before we reach one which will bear the strain of a critical examination in the light of further evidence. But at this stage in historical investigation it is generally the want of evidence of a sufficiently complete and continuous character, rather than difficulties of method, which forces us to leave the problem unsolved. It is, for instance, practically impossible to obtain reliable evidence as to the regularity of employment in any industry in the 17th century, and the best approximations and devices we can invent are very poor substitutes for what we really want. For this reason guess-work must continue to play an important part in economic history. But every genuine attempt to overcome its difficulties brings us into closer touch with the period we are examining; and though we may not be able to throw our conclusions into the form of large generalizations, we shall get to know something of the operation of the forces which determined the economic future of England; understand more clearly than our forefathers did, for we have more information than they could command, and a fuller appreciation of the issues, the broad features of English development, and be in a position to judge fairly well of the measures they adopted in their time. By comparing England with other countries we may be able in the distant future to reach conclusions of some generality as to the laws of growth, maturity, and decay of industrial nations. But, like the early statisticians of the 17th century, economic historians are the "beginners of an art not yet polished, which time may bring to more perfection."

***The investigation of modern questions.***

When we come to exclusively modern questions, there is no reason or necessity for a fundamental change of method. We cannot suppose that there occurred, at or about the commencement of the 19th century, a breach of historical continuity of such a character that institutions, customs, laws, and social conventions were suddenly swept away, the bonds of society loosened, and the state and people of England dissolved into an aggregate of competing individuals. The adoption of machinery gradually revolutionized the methods of production; but in the first instance only certain industries were affected, and those not at the same time or in the same degree; old laws grown obsolete were repealed, but other laws affecting wage-earners and employers took their place, more complicated and elaborate than the Elizabethan code. Trade unions, so far from disappearing, were legalized, gathered strength from the changes in industrial organization, and nowhere became so powerful as in the most progressive industries; while other forms of combination appeared, incomparably stronger, for good or evil, than those of earlier times. But while we recognize these facts, we must not suppose that we have to study the action of men as though they were all enrolled in organized associations or covered by stringent laws which were always obeyed. There has never been in the history of English industry such licence as we find in certain directions in the earlier part of the 19th century.

It is not in the decay of combination and monopoly or in the growth of competition that we must look for the distinctive characteristics of modern problems. A 17th-century monopoly was a very weak and ineffective instrument compared with a modern syndicate; the Statute of Apprenticeship was certainly not so widely enforced as the "common rules" of trade unions; and many of the regulations of past times, which look so complicated to modern eyes, were conditions of free enterprise rather than restraints upon it. It is due to the influence of the *laisser faire* doctrine that we regard law and regulation as a restraint on liberty. As a maxim for guidance

in public affairs, *laisser faire* was genuinely relevant at the end of the 18th and the beginning of the 19th century, when the Statute Book was cumbered with vexatious and obsolete laws. As an explanation of what has taken place during the last sixty years, or of the actual economic life of the present day, it is ludicrously inadequate. Competition, in the sense in which the word is still used in many economic works, is merely a special case of the struggle for survival, and, from its limitation, does not go far towards explaining the actual working of modern institutions. To buy in the cheapest market and sell in the dearest; to secure cheapness by lowering the expenses of production; to adopt the less expensive rather than the more expensive method of obtaining a given result—these and other maxims are as old as human society. Competition, in the Darwinian sense, is characteristic not only of modern industrial states, but of all living organisms; and in the narrower sense of the "higgling of the market" is found on the Stock Exchange, in the markets of old country towns, in mediæval fairs and Oriental bazaars. In modern countries it takes myriads of forms, from the sweating of parasitic trades to the organization of scientific research. Economic motives, again, are as varied as the forms of competition, and their development is coeval with that of human society. They have to be interpreted in every age in relation to the state of society, the other motives or ideals with which they are associated, the kind of action they inspire, and the means through which they operate. Apparently the same economic motives have led in the same age and in the same nation to monopoly and individual enterprise, protection and free trade, law and anarchy. In our own time they have inspired both the formation of trade combinations and attempts to break them up, hostility to all forms of state interference and a belief in collectivism.

***The distinctive features of modern problems.***

The conditions which are peculiar to the modern world are the large numbers we have to deal with, the vast and fairly homogeneous areas in which justice is administered and property secured, and the enormously increased facilities for transport and communication. These conditions are of course not independent of each other, and they have brought in their train many consequences, some good and some bad. But they supply the bases for that general theory which, as we have seen, is indispensable in economic investigation. From the standpoint of general theory economic movements assume an impersonal character, and economic forces operate like the forces of nature. Although economic motives have become more complex, they have just as much and no more to do with general economic reasoning and analysis than the causes of death with the normal expectation of life, or domestic ideals with the birth-rate. So far as we have anything to do with psychology at all, it is the psychology of crowds and not of individuals which we have to consider. If we study the economy of a village, the idiosyncrasies of every individual in it are of importance. If the village is replaced by a large area, inhabited by millions, with modern facilities of communication, it is a matter of observation and experience that for the purposes of general reasoning the idiosyncrasies of individuals may be neglected. Whether such large numbers have the character of the "economic man" of the early economists matters very little. All the assumptions we require are furnished by observation of people in the mass and the larger generalizations of statistics. Thus we can construct a kind of envelope of theory, which, by careful testing as we proceed, can be made to indicate in a general manner the reactions of one part of the activities of the economic world upon the others, and the interdependence of the several parts. From its very nature this general theory can never correspond strictly to the actual life and movement of any given state. It is useful and necessary, and plays somewhat the same part in economic investigation as ton-mile statistics do in the administration of a railway. To express in any language or to illustrate by any images, from a purely objective standpoint, the infinitely complicated movements of the actual world, is a task far beyond human capacity.

With the aid of this general theory the methods we have sketched in relation to historical problems apply with greater force to the special problems of modern times, and are rewarded with results more accurate, more fruitful, more relevant to difficulties which all civilized nations have to face, than those of historical research. To many minds the interest and usefulness of economics depend entirely on the application of these methods, for it is the actual working of economic institutions about which the statesman, the publicist, the business man, and the artisan wish to know. Under the conditions we have described, many of the most interesting problems of our own time, when they are once defined, resolve themselves into statistical inquiries. But in most cases such an inquiry cannot be successfully carried out by a mere statistician. Definite economic problems can very rarely be dealt with by merely quantitative methods. In the tabulation and interpretation of statistical evidence, as in its collection, it is scarcely possible to overrate the importance of wide knowledge and experience. There is another very important instrument of investigation which can be used in our own time, but cannot be employed in historical research. Historical documents, however detailed, rarely show all the factors we have to deal with or fully explain a given situation. No sane person would suppose that the minutes of a modern legislative body explain the steps by which legislation has been passed, or the issues really involved. The ostensible cause of a modern labour dispute is frequently not the real or the most important cause. In modern problems we can watch the economic machine actually at work, cross-examine our witnesses, see that delicate interplay of passions and interests which cannot be set down or described in a document, and acquire a certain sense of touch in relation to the questions at issue which manuscripts and records cannot impart. We can therefore substitute sound diagnosis for guess-work more frequently in modern than in historical problems.

***Application to modern problems.***

What then, it may be asked, becomes of the "old Political Economy"? Of what possible use are the works of the so-called classical writers, except in relation to the history of economics and the practical influence of theory in past times? If we take the mere popular view of what is meant by the "old Political Economy," that is, that a generation or so ago economics was comprised in a neatly rounded set of general propositions, universally accepted, which could be set forth in a text-book and learnt like the multiplication table, it is not incumbent on the present generation to define its attitude at all. In this sense of the words, there was no faith delivered to our fathers which we are under any obligation to guard or even explain. If by the "old Political Economy" we mean the methods and conclusions of certain great writers, who stood head and shoulders above their contemporaries and determined the general character of economic science, we are still under no obligation to define the attitude of the present generation with regard to them. The fact that Adam Smith, with the meagre materials of the 18th century at his disposal, saw his way to important generalizations which later research has established on a firm basis, may enhance greatly the reputation of Adam Smith, but does not strengthen the

***The "old political economy."***

generalizations. They stand or fall by the strength of the evidence for or against them. In the history of economics or the biography of Ricardo it is of interest to show that he anticipated later writers, or that his analysis bears the test of modern criticism; but no economist is under any obligation to defend Ricardo's reputation, nor is the fact that a doctrine is included in his works to be taken as a demonstration of its truth. The appeal to authority cannot be permitted in economics any more than in chemistry, physics, or astronomy. But the cases stated above suggest more or less false issues. There has been no revolution in economic science, and is not likely to be any. The question we have really to determine is how we can make the best use of the accumulated knowledge of past generations, and to do that we must look more closely into the economic science of the 19th century.

Any one who has taken the trouble to trace the history of one of the modern schools of economists, or of any branch of economic science, knows how difficult it is to say when it began. "Anticipations" of method and doctrine can generally be found by the diligent investigator in the economic literature of his own or a foreign country. So that cross-sections of the stream of economic thought will reveal the existence, at different times, in varying proportions and at different stages of development, of most of the modern "schools." Again, the classification of an economic bibliography at once shows how varied has been the character of economic investigation, ranging from the most abstract speculation on the one hand to almost technical studies of particular trades on the other. Of the great army of writers who flourished in the first half of the 19th century some were closely identified with the utilitarian school, and the majority were influenced in a greater or less degree by the prevailing ideas of that school. Others, however, were hostile to it. In many works, such as those of a statistical or historical character, there are frequently to be found passages which could have been written in no other period, but are only of the nature of ejaculations and do not affect the argument. In stating the position of economics during this time we cannot ignore all writers, except those who belonged to one group, however eminent that group may have been, simply because they did not represent the dominant ideas of the period, and exercised no immediate and direct influence on the movement of economic thought. We must include the pioneers of the historical school, the economic historians, the socialists, the statisticians, and others whose contributions to economics are now appreciated, and without whose labours the science as we know it now would have been impossible. If we take this broadly historical view of the progress of economics, it is obvious that even in England there was no general agreement, during the 19th century, as to the methods most appropriate to economic investigation.

Suppose, now, we ignore the writers who were inaugurating new methods, investigating special problems or laboriously collecting facts, and concentrate attention on the dominant school, with its long series of writers from Adam Smith to John Stuart Mill. It is the work of these writers which people have in mind when they speak of the "old Political Economy." There are several quite distinct questions we can ask with regard to them. That they must be studied closely by every one who wishes to follow the history of economics goes without saying. That they must be studied by the economic historian is equally clear, owing to their practical influence and the fact that they furnished the theoretical bases of much of the economic policy of the 19th century. This is true whether their method is good or bad, whether their conclusions are true or false. It is not so easy to determine their relevance and usefulness in relation to distinctively modern problems, or to indicate within what limits their work is of permanent value, and we can only deal with these questions in their more general aspects.

It must be clear to every observer that the economists of the classical period, with the one exception of Adam Smith, will speedily share the fate of nearly all scientific writers. They will be forgotten, and their books will not be read. Adam Smith's *Wealth of Nations*, if it has ever been, has long ceased to be a scientific text-book. Whether a modern economist accepts his views or not is of no importance. There is probably not a single chapter in the *Wealth of Nations* which would be thoroughly endorsed by any living economist. But the reputation of the book and its author is quite independent of considerations of this kind. The *Wealth of Nations* is one of the great books of the world, many of the sayings of which are likely to be more frequently quoted in the future than they have been in the 19th century. Malthus is already an author whose name is probably more widely known than that of any other economist, but whose works are rarely read, and studied only by a small proportion of the few people who write books on the history of economic theory. Of economic students, many are unaware of the fact that he wrote any other book than the *Essay on the Principle of Population*, and what is of permanent importance in that work is contained in the generalization which it suggested to Darwin. Moreover, modern economists, while accepting in the main the general tenor of Malthus's theory of population, would not agree with his statement of it. Like Malthus, Ricardo owes his reputation very largely to the theory associated with his name, though it has long ceased to be stated precisely in the terms he employed. But there are very few people in the world who have made a careful study of his works; and although his theory of rent has a wide and increasing application in economics, it is not comparable in general scientific importance with Malthus's theory of population. It is already impossible to take J. S. Mill's *Principles of Political Economy* as a text-book. Important as it was for thirty or forty years, it will soon be as little read as M'Culloch's *Principles.* For the rest of the economists of this period, it is difficult to see how they can escape oblivion. When the generation whose economic training was based upon Mill has died out, the relevance of "the old Political Economy" is not likely to be a question of any interest to ordinary educated men and women, or even to the great mass of economic students.

The explanation of this decay of interest does not lie upon the surface. It is frequently supposed that the influence of the "old Political Economy" has been gradually undermined by the attacks of the historical school. But great as the achievements of this school have been, it has not developed any scientific machinery which can take the place of theory in economic investigation. If our view is correct that, broadly speaking, the two ways of regarding economic questions are complementary rather than mutually exclusive, there does not seem to be any reason why the growth of the historical school should have been destructive of the "old Political Economy" if it had been well founded. The use of the historical method has, in fact, raised more reputations than it has destroyed, because by keeping carefully in view the conditions in which economic works have been written, it has shown that many theories hastily condemned as unsound by *à priori* critics had much to be said for them at the time when they were propounded. This observation is true not only of old-world writers like the Mercantilists, but also of Ricardian economics. No one is concerned to prove that the Ricardian

economics applies to the manorial system, and it is generally supposed at any rate that the world has been approximating more and more nearly during the last century to the conditions assumed in most of the reasoning of that school. On the principles we have explained, therefore, the Ricardian economics should supply just that body of general theory which is required in the investigation of modern economic problems, and the reputation of at any rate the leading writers should be as great as ever. It would be of immense advantage from a scientific point of view if this could be taken for granted, if for a time the work of the classical economists could be considered final so far as it goes, and for the purposes of investigation regarded as the theoretical counterpart of the modern industrial system. This assumption, however, has been made quite impossible, not by the historical school, but by the criticism and analysis of economists in the direct line of the Ricardian succession.

Modern economic criticism and analysis has destroyed the authority of the "old Political Economy" as a scientific system. The assumptions, the definitions, the reasoning, the conclusions of the classical writers have been ruthlessly overhauled. Defects in their arguments have been exposed to view by those who are most concerned to defend their reputation. Writers with none of the prejudices of the historical school, but with the cold and remorseless regard for logic of the purely objective critic, have pointed out serious inconsistencies here, the omission of important factors there, until very little of the "old Political Economy" is left unscathed. In fact, there never was a scientific system at all. What was mistaken for it was fashioned in the heat of controversy by men whose interests were practical rather than scientific, who could not write correct English, and revealed in their reasoning the usual fallacies of the merely practical man. So the "old Political Economy" lies shattered. It is useless to suppose that this destructive criticism from within can be neutralized by generously sprinkling the pages of the classical writers with interpretation clauses. This may serve to show that the ideals of our youth were not without justification; but the younger generation, which does not care about our ideals, and looks to the future rather than the past, will not read annotated editions of old books, however eminent their authors. If the Ricardian school of economists had been merely philosophers, or even a group like the French physiocrats, this state of things might be regarded with equanimity. We might assume that criticism and analysis had separated the wheat from the chaff in their writings, that everything of permanent value had probably been preserved and incorporated in the works of later economists. But the character of much of their work makes this assumption impossible. It is, in fact, quite true that many of them were more interested in practical aims than in the advancement of economic science. We may talk of the assumptions implicitly involved in Ricardo's works. In reality we do not know what those assumptions were; we only know what assumptions we should make in order to reach the same conclusions, and they may be very different from "the mind of Ricardo." Ricardo's works, in fact, do not explain a theoretical system, but contain the matured reflexions, more or less closely reasoned, of a man of great mental power looking out on the world as it appeared to a business man experienced in affairs. The conclusions of such a work are of wider significance than the assumptions we attribute to the author would warrant. They are not expressed in terms which satisfy our canons of scientific accuracy. Dissected sentence by sentence, the book may be shown to be a mass of inconsistencies. If it has the misfortune to be systematized by an enthusiastic but dull and incompetent disciple, it may appear even absurd. But after all the misinterpretation of contemporaries and the destructive criticism of later times, the book as a whole leaves upon us an impression of peculiar strength and charm, and imparts a sense of the relations of things truer, because less mechanical, than the laboured reasoning of smaller men. Such is the character of much of the work of Ricardo and some of his contemporaries. We think that the decay of interest in these writers involves a real loss, and that students of modern problems may do worse than read Ricardo and his school. Some of the criticism of their works, necessary and useful as it has been, will probably be corrected later on by that breadth of view and sense of proportion which has enabled us to appreciate justly the achievements of lesser men in more remote times. But rehabilitation in accordance with the canons of historical justice will not restore the lost influence of the Ricardian school. Their achievements in the 19th century will be fully acknowledged, but the relevance of their work to the problems of the 20th century will be admitted less than at the present time.

*Ricardo's limitations.*

*Economics a conservative science.*

In a subject like economics it must always be very difficult to decide how far a departure from the traditional form and expression of its main doctrines is necessary or desirable. No one who is really experienced in economic investigation cares to emphasize the originality, still less the revolutionary character of his own work. It is much more likely than not that some principle which for the moment seems new, some distinction which we may flatter ourselves has not been observed before, has been pointed out over and over again by previous writers, although, owing to special circumstances, it may not have received the notice it deserved. Economics is therefore, on the whole, an intensely conservative science, in which new truths are cautiously admitted or incorporated merely as extensions or qualifications of those enunciated by previous writers. This procedure has its advantages, but it may easily become dangerous by destroying the influence of the science it is meant to preserve. It is not unlike the procedure of the canonists and casuists of the Middle Ages with regard to the doctrine of usury, by which the doctrine was to all appearances preserved intact while in reality it was stripped of all its original meaning by innumerable distinctions "over-curious and precise." In the same way the doctrines of the classical economists may be adapted by interpretation clauses and qualifications the exact force of which cannot be tested or explained, so that we do not know whether the original proposition is to be considered substantially correct or not. The result will be that while the doctrines are apparently being brought into closer correspondence with the facts of life, they will in reality be made quite useless for practical purposes or economic investigation. It is easier to point out the danger than to suggest how it should be met. The position we have described is no doubt partly due to the unsettlement of economic opinion and the hostile criticism of old-established doctrines which has characterized the last generation. Or it may be the result of economic agnosticism, combined with unwillingness to cut adrift from old moorings. Whatever the cause, the complete restatement of economic theory, which some heroic persons demand, is clearly impossible, except on conditions not likely to be realized in the immediate future. The span of life is limited; the work requires an extensive knowledge of the economic literature of several countries and the general features of all the important departments of modern economic activity. In general theory special studies by other men cannot play the same part as they do in historical and statistical work. In historical and statis-

tical investigation, or in special studies of particular subjects, it is possible, given the pecuniary means, to organize a whole army of skilled assistants, and with ordinary care to combine the results of their separate efforts. In general theory the inverse rule seems to prevail. There the unity of conception and aim, the firm grip of all the different lines of argument and their relation to each other, which are required, can only be given by a single brain. But no one individual can do original work over the whole field. He is lucky if he can throw new light on a few old propositions. For the rest, he can only, with the utmost caution, adopt the suggestions of other minds as qualifications of old doctrines, never feeling quite sure that he is right in doing so. A complete restatement could only be undertaken by a group of men, trained in much the same conditions, accustomed to think and work together, each one engaged on a special department, but all acting under the control of one master-mind. This is largely a question of the organization of economic studies, and it is of the greatest importance that, if possible, such an effort should be made to present in a connected form the best results of modern criticism and analysis.

*Some recent developments of economic theory.*

Economics is unlike many other sciences in the fact that its claim to recognition must be based upon its practical utility, on its relevance to the actual life of the economic world, on its ability to unravel the social and economic difficulties of each generation, and to contribute to the progress of nations. The very effectiveness of modern criticism and analysis, which has brought great gains in almost all branches of economic theory, has made the science more difficult as a subject of ordinary study. The extensions, the changes or the qualifications, of old doctrines, which at any rate in the works of responsible writers are rarely made without good if not always sufficient reason, have modified very considerably the whole science, and weakened the confidence of ordinary educated men in its conclusions. In the case of many subjects this would matter very little, but in that of economics, which touches the ordinary life of the community at so many points, it is of great importance, especially at a time like the present, when economic questions determine the policy of great nations. The "economic man" of the earlier writers, with his aversion from labour and his desire of the present enjoyment of costly indulgences, has been abandoned by their successors, with the result that in the opinion of many good people altruistic sentiment may be allowed to run wild over the whole domain of economics. The "economic man" has, on the other hand, been succeeded by another creation almost as monstrous, if his lineaments are to be supposed to be those of the ordinary individual—a man, that is, who regulates his life in accordance with Gossen's Law of Satiety, and whose main passion is to discover a money measure of his motives. It is extremely important to consider how far the economic conceptions based upon this view of the action of men in the ordinary business of life—such, for example, as the doctrine of marginal utility—depend for their truth and relevance on the fact that in economics we are dealing with large aggregates. The earlier writers generally assumed perfect mobility of labour and capital. No economist would deliberately make that assumption now unless he were dealing with some purely theoretical problem, for the solution of which it was legitimate at some stage in the reasoning. Many of the questions of the greatest practical importance at the present time, such as the competition between old and new methods of manufacturing commodities substantially the same in kind and equally useful to the great body of consumers, arise largely from the immobility of capital or labour, or both of them. But it is obvious that if the assumption of perfect mobility is invalid, there is scarcely any economic doctrine identified with the earlier writers which may not require modification, in what degree it is impossible to say without very careful investigation. Much suggestive work on this subject of a general character is incorporated in recent economic books, but there is room for a whole series of careful monographs on a question of such fundamental importance. The same may be said of another subject, too frequently neglected by earlier writers, to which due significance has been given in the best recent work, namely, time in relation to value. It would perhaps be too much to say that the full consideration of this point has revolutionized the theory of value, but it has certainly created what seems almost a new science in close contact with the actual life of the modern world.

Some doctrines of the earlier economists, such as the Wages Fund Theory, have practically been abandoned in recent times, though it may be said that they contained a certain amount of truth. Others, which were considered of fundamental importance, owe their position in modern economics and the form in which they are stated to the "tradition of the elders." If they could, by some happy chance, have been left for discovery by modern economists, they would without doubt have received different treatment, to the great advantage of economic science. Such a doctrine is the so-called Law of Diminishing Returns, which Mill considered "the most important proposition in Political Economy." "Unless this one matter," he says, "be thoroughly understood, it is to no purpose proceeding any further in our inquiry." "Were the law different, nearly all the phenomena of the production and distribution of wealth would be other than they are." On the other hand, Thorold Rogers, not to speak of earlier objectors, described the law as a "dismal and absurd theorem." The opinions of recent economists appear to fluctuate between these two extremes. The law may apparently be "a general rule" or "a tendency" which is liable to be "checked," or a particular case of the law of the conservation of energy. If we go to Mill to discover what it is, we find that "it is not pretended that the law of diminishing return was operative from the beginning of society; and though some political economists may have believed it to come into operation earlier than it does, it begins quite early enough to support the conclusions they founded on it." "It comes into operation at a certain and not very advanced stage in the progress of agriculture." But this very important stage in the history of a nation is not defined or clearly illustrated. We are told that we can see "the law at work underneath the more superficial agencies on which attention fixes itself"; it "undergoes temporary suspension," which may last indefinitely; and "there is another agency, in habitual antagonism" to it, namely, "the progress of civilization," which may include every kind of human improvement. Mill apparently is not content with the confusion between "law" and "agency" or "force," but opposes the one to the other. He is constantly speaking in terms which imply the conquering of one law by another, a habit from which his successors have not freed themselves; and the theory of natural processes which appears to have satisfied him, was that when two forces come into operation there is a partial or complete suspension of one by the other. In modern economics "fertility" has no very definite meaning. It may mean what is ordinarily understood by the word—climate, rainfall, railway rates, or anything else except "indestructible powers of the soil." To speak of "additional labour and capital" without reference to the kind and quality of the labour and capital, and the manner in

which they are employed, organized, and directed, throws very little light on agriculture. Every improvement involves, from a quantitative point of view, more or less of capital or of labour, so that it is the "antagonizing" influences, which are nearly all qualitative, which appear to be really important. It is therefore extraordinarily difficult at present to know what happens, or rather what would happen if it were not prevented, when a country reaches "the stage of diminishing returns"; what precisely it is which comes into operation, for obviously the diminishing returns are the results, not the cause; or how commodities "obey" a law which is always "suspended." Possibly the next few years of English industrial history will furnish many illustrations of the law of diminishing returns. We can only say that it requires investigation and restatement.

Closely related to the law of diminishing returns is the Theory of Rent. No economic doctrine so well illustrates the achievements and the defects of modern economic analysis. Ricardo's statement of the theory left upon the world an impression, not wholly just, of singular clearness. He employed the theory with wonderful success in unravelling the problems of his time. Its importance has not been seriously, or at any rate successfully, called in question. Treated at first as a doctrine peculiarly applicable to land, with a certain controverted relevance to other natural agents, it has been so extended that there is scarcely any subject of economic study in which we may not expect to find adaptations or analogies, so that Ricardo seemed to have discovered the key of economic knowledge. But it was discovered that there were no "indestructible powers of the soil"; that the fertility of land in a country like England is almost entirely the result of improvement at some time or other; that "advantage of situation" includes very much more than the words in their literal sense imply; that both "fertility" and "advantage of situation" include many kinds of differential advantage; that in some circumstances rent does not enter into the price of agricultural and other produce, and that in others it does. Moreover, the study of the theory of rent has had a very great influence on all branches of economics, by destroying the notion that it is possible to draw sharp lines of distinction or deal with economic conceptions as though they were entirely independent categories. That modern economic analysis is incomparably more accurate than that of earlier times there can be no question. But the net result of the development of the doctrine of rent is that all problems in which this factor appears, and they embrace the whole range of economic theory, must apparently be treated on their merits. In its modern form the doctrine is far too general to be serviceable without the closest scrutiny of all the facts relating to the particular case to which it is applied. To deal adequately with the numerous extensions or qualifications of these and other doctrines in the hands of modern economists would involve us in an attempt to do what we have already said is impossible except on conditions not at present realized. It is clear that in the interests of general economic theory we require a vast number of special studies before an adequate restatement can be undertaken.

It must be clearly recognized that the functions of economic science in the present requirements of the world cannot possibly be discharged by treatises on economic theory. The relations between general theory and special studies conducted on the lines we have indicated have completely changed in the last thirty years. General theory never has been, and in the nature of things never can be, the actual reflex of the life and movement of the economic world. It never has been, and never can be, more than an indication of the kind of thing which might be expected in a purely hypothetical world. When the aim of the man of affairs and the hypothesis of the economist was unrestricted competition, and measures were being adopted to realize it, general theory such as the classical economists provided was perhaps a sufficiently trustworthy guide for practical statesmen and men of business. If only people can be got to believe in them, a few abstract principles are quite enough to destroy an institution which it has taken centuries to create. But a new institution cannot be made on the same terms. The modern industrial system has brought with it an immense variety of practical problems which nations must solve on pain of industrial and commercial ruin. For these problems we want, not a few old-established general principles which no one seriously calls in question, but genuine constructive and organizing capacity, aided by scientific and detailed knowledge of particular institutions, industries, and classes. Just as the historical school grew up along with the greatest constructive achievement of the 19th century, namely, the consolidation of Germany, so the application to modern problems of the methods of that school has been called forth by the constructive needs of the present generation. We have already shown how these methods, in their turn, require the aid of general theory, but not of a general theory which tries to do their work. In fact, every attempt to make it do so must inevitably fail. How can such a huge mass of general propositions as are necessarily included in a system of economics ever be thoroughly tested by an appeal to facts? If they are not so tested, the general theory will remain a general theory, of no practical use in itself, until the end of time. If they are to be tested, an indefinitely large number of special studies must be made, for which the original materials must be collected and examined. That is, original investigation of special problems has to be carried out on a more gigantic scale than any economist of the historical school ever dreamt of or the world requires, with the certain knowledge that at the end of it all the general theory will not correspond with the facts of life. For there is all the difference in the world between using a body of general theory as an indication of the factors to be considered in the study of a special problem, and undertaking special studies with a view to testing the general theory. If the necessary limitations of general economic theory are recognized, most of the difficulties we have noticed disappear. Now that the "industrial revolution" has extended practically all over the world, so that we have several countries carrying on production by modern methods, it is easily possible to sketch the main features of industrial and commercial organization at the present time, to describe the banking and currency systems of the principal nations, their means of transport and communication, their systems of commercial law and finance, and their commercial policy. It is true that at present very little work of this kind has been done in England, but innumerable books, many of them about England, have been written by thoroughly competent economists, in French, German, and other languages. So that no great amount of original work is required for a reliable account of those general features of the modern system which should form the introduction to economics. The general theory which we require should be sketched in firm and clear outline, leaving the detailed qualifications of broad principles to special studies, where they can be dealt with if it is necessary or desirable, and examined by statistical and other tests. For such a general theory there is ample material in the economic literature of all civilized countries. It is of the utmost import-

***Relations between general economics and special studies.***

ance that the economic terms, which are also, though in many cases with an entirely different meaning, the terms of business and commerce, should as far as possible be used in their common and ordinary English sense: that they should correspond in meaning with the same words when used in description, in law, accountancy, and ordinary business. This is no doubt a difficult matter. But some change in this direction is necessary both in the interests of the science itself and of its practical utility. All the materials for investigation, all the facts and figures from which illustrations are drawn, all methods of keeping accounts in England, assume the ordinary English tongue. There are few if any conceptions in economics which cannot be expressed in it without depleting the ordinary vocabulary. At present the language of economics is for the ordinary Englishman like a foreign language of exceptional difficulty, because he is constantly meeting with words which suggest to his mind a whole world of associations quite different from those with which economic theory has clothed them. The refinements of economic analysis, as distinguished from its broader achievements, should be reserved for special studies, in which a technical scientific terminology, specially devised, can be used without danger of misconception. But in a subject like economics obscurity and an awkward terminology are not marks of scientific merit.

Economic studies should be as relevant to existing needs as those of engineering and other applied sciences. The scientific study of practical problems and difficulties is far more advanced in almost every civilized country than it is in England, where the limited scale upon which such work is carried on, the indifference of statesmen, officials, and business men, and the incapacity of the public to understand the close relation between scientific study and practical success, contrast very unfavourably with the state of affairs in Germany or the United States. The backwardness of economic science is an index of the danger which threatens the industrial and commercial supremacy of the United Kingdom. There are at the present time very few questions of public or commercial importance upon which the best and most recent investigations are to be found amongst English works. This would matter very little, perhaps, if Englishmen had a firm belief, established by actual experience, in the soundness of their policy, the present security of their position, and the sufficiency of their methods to strengthen or maintain it. But this is very far from being the case. If we take, for example, the corner-stone of the British commercial system, namely, the policy of free trade, the present generation does not read the economic works which supplied the theoretical basis of that policy, and if it did, would not be convinced by them. The generation which knew Cobden and Bright is rapidly dying out. The great men of their period are merely historical figures, not so real to the present generation as the younger Pitt was to their grandfathers. Long before his death, Bright's references in public speeches to the achievements of the Anti-Corn Law League were received with respectful impatience, and Peel's famous speech on the repeal of the Corn Laws would not convince the German Reichstag or a modern House of Commons. The result is that free trade has ceased to be an article of faith, or even in any real sense a doctrine of expediency. It is rather an old habit for which the ordinary English manufacturer could give no very reasonable explanation, which is not likely to be given up as long as the generation now over fifty years of age has the predominant influence in commerce and public affairs, but for which a younger generation will care no more than their grandfathers did for the mercantile system, unless it can win their adhesion as a policy well designed to realize the aims they will have in view. Hence free trade is in serious jeopardy unless it can be restated in terms which have a direct relevance to the present position of England and present conditions of international trade. If the Imperialist tendencies of the present time continue, as no doubt they will, this question will become one of burning interest. No great scheme of national or Imperial consolidation has ever been carried through without raising and solving questions of commercial policy; and although there is no reason why the consolidation of the British Empire should involve the destruction of the established commercial system of the United Kingdom, and every historical and scientific reason for safeguarding the inheritance of the past, we may see a revival of old fallacies in a new form. It should be the work of economic science ruthlessly to analyse the existing situation, explain the issues involved in the commercial policy of different countries, and point out the alternative methods of dealing with present difficulties, with their probable results.

***Economic problems in Great Britain.***

The commercial policy of a state is merely the reflex of its system of public finance. The absence of conviction in regard to British commercial policy has its counterpart in the attitude of many men to the financial system of the country. It is not often that the eulogies showered upon it in the past are repeated at the present time. The difficulty appears to be caused partly by the great increase in military and naval expenditure, which has been made necessary by the exceptional demands of a state of war and the great development of foreign Powers, partly by the great extension of the functions of the State during the latter part of the 19th century. The former causes are partly permanent, partly temporary; but those of a permanent character are likely to increase in force, and those of a temporary character will leave a deposit in the shape of an addition to the normal expenditure of the central Government. The extension of Government functions is much more likely to continue than to be checked. Normal expenditure is therefore almost certain to rise. It is almost inconceivable that it will fall. Meanwhile, in spite of the vast increase in national wealth, it is a matter of increasing difficulty to meet a comparatively slight strain without recourse to measures of a highly controversial character; and it is certain that no important new source of revenue can be suggested which will not raise, in an acute form, questions of commercial policy and the relations between the United Kingdom and the Colonies. Here there is room for a whole series of important monographs. There is no civilized country in which questions of public finance, in a concrete form, have received so little attention as in England.

***Commerce and finance.***

The development of the powers of the central Government has been less than that of the functions of local governing authorities. This, again, is a movement much more likely to extend than to be checked. Local governing authorities now discharge economic functions of enormous importance and complexity, involving sums of money larger than sufficed to run important states a generation ago. At present we do not know precisely what happens. The scientific study of the economics of local administration is in its infancy. It is of the utmost importance that it should be taken up in earnest by economists. These questions of commercial policy and local government are closely bound up with the scientific study of the transport system. On this important subject there is at present not a single treatise of first-rate importance by an English writer, and there is only one English railway company which records in a suitable form the

data necessary not only for scientific study but for efficient administration. So that, although the British Empire contains within itself every known species of railway enterprise, the study of railways and other means of transport, and their relation to the business, the commerce, and the social life of the country, is deplorably backward. It is obvious that no inquiry into commercial policy, or into such social questions as the housing of the poor, can be effective unless this deficiency is remedied.

The whole social and political fabric of the British Empire depends upon the efficiency of its industrial system. On this subject many monographs and larger works have been published in recent years, but dealing rather with such questions as trade unionism, co-operation, and factory legislation, than the structure and organization of particular industries, or the causes and the results of the formation of the great combinations, peculiarly characteristic of the United States, but not wanting in England, which are amongst the most striking economic phenomena of modern times.

These are some of the questions which might with advantage absorb the energies of the rising generation of economists. It would be possible to add to their number almost indefinitely, but these press for immediate attention. The claim of economics for recognition as a science and as a subject of study must be based on its relevance to the actual life of the economic world, on its ability to unravel the practical difficulties of each generation, and so contribute to the progress of nations.

It is impossible to give even a select bibliography which is at all adequate of the publications of recent years on *Economics*. The most important general work published in English is Marshall's *Principles of Economics*, vol. i., 1st edition, 1890; 4th edition, 1898. J. Shield Nicholson's *Principles of Political Economy*, 3 vols., which is now completed, not only gives a survey of economic principles since Mill's time, but contains much suggestive and original work. The writer of this article is much indebted to the works of Schmoller, particularly his *Grundriss der Allgemeinen Volkswirtschaftslehre* (1900), and Adolph Wagner, particularly his *Grundlegung der Politischen Oekonomie*. On the history of economic theory, Cannan's *History of the Theories of Production and Distribution* (1776–1848) is an admirable criticism, from a purely objective standpoint, of the works of the English classical writers. The most important English works published in recent years on general English economic history are Cunningham's *Growth of Industry and Commerce* and Ashley's *Economic History*, while Vinogradoff's *Villenage in England* and Maitland's *Domesday Studies* are of great importance to the student of early economic institutions. D'Avenel's *Histoire Économique de la Propriété*, &c. (1200–1800), is a monumental work on the history of prices in France. Some recent books dealing with special subjects are likely to take a very high place in economic literature. We may mention particularly Charles Booth's *Labour and Life of London* and Sidney and Beatrice Webb's *History of Trade Unionism* and *Industrial Democracy*. These books are generally regarded as typical of the best English work of recent years in economic investigation. We may also mention Schloss's *Methods of Industrial Remuneration*, a most important contribution to the study of the wages question; C. F. Bastable's works on *International Trade* and *Public Finance*; George Clare on the *Money Market* and the *Foreign Exchanges*; and A. T. Hadley's *Economics: An account of the relations between private property and public welfare* (1896). Studies of particular questions, both concrete and theoretical, in foreign languages are too numerous to specify, and much of the best modern work is to be found in economic periodicals.

(W. A. S. H.)

**Ecuador,** a country of South America extending between Colombia and Peru from 1° 56′ N. lat. to about 5° 30′ S. lat., and from the Pacific coast to a distance inland not yet determined. The boundary dispute between Colombia, Ecuador, and Peru was, by agreement of 15th December 1894, submitted to the arbitration of the Spanish Crown, but no award had been made up to the beginning of 1902, nor had any definite steps been taken to execute a survey of the frontier. The climate is on the whole healthy, especially in the inter-Cordilleran valley. Intermittent fevers, frequent in the coast region, are unknown in the highlands, where also pulmonary diseases are rare. The average rainfall at Quito is about 39 inches. The death-rate at Quito in 1892 was stated to be 36 per 1000.

*Population.*—The area has never been ascertained by survey, but is estimated at 118,630 square miles, an estimate which includes a vast territory still in dispute. No census has ever been taken, and the generally accepted estimate of the population is that of Cervallos, who for 1889 put the total number of inhabitants at 1,272,160. The following table shows the population of the fifteen provinces, the territory of Oriente, and the Galapagos Islands, which in 1885 were made dependent on the province of Guayas:—

| | Population, 1889. | | Population, 1889. |
|---|---|---|---|
| Carchi | 36,000 | Rios | 32,800 |
| Imbabura | 67,940 | Oro | 32,600 |
| Pinchincha | 205,000 | Guayas | 98,042 |
| Leon | 109,600 | Manabi | 64,123 |
| Tunguragua | 103,033 | Esmeraldas | 14,553 |
| Chimborazo | 122,300 | Oriente | 80,000 |
| Cañar | 64,014 | Galapagos Islands | 300 |
| Azuay | 132,400 | | |
| Loja | 66,456 | | |
| Bolivar | 43,000 | Total | 1,272,161 |

The population contains approximately 120,000 whites, 450,000 of mixed races, and 702,000 Indians. The isolated position of the inland towns has helped their white inhabitants to preserve the characteristics of the original Spanish settlers. The offspring of the intermixture of whites and Indians are called, in the language of the country, *mestizos*, and the offspring of mestizos and Indians, *cholos*. The crossing of white and negro, and of negro or mulatto and Indian, produces the classes named respectively *mulattos*, *zambos*, and *zambaigos*. The colour among these people confers superiority in rank, or at least in self-esteem. The half-breeds, whether those between Spaniards and Indians or Indians and negroes, are indolent and unintelligent. The Indians as a rule are sturdily built and have great power of endurance, travelling immense distances over mountainous country without undue fatigue. They are extremely docile, except when excited by drink. A few of the tribes near the seaboard in the province of Esmeraldas have a large admixture of negro blood from slaves formerly employed in that district. The foreigners resident in Ecuador number altogether about 6000, some 5000 being natives of South or Central America, 700 Europeans, and 300 Chinese. The population of Quito is estimated at 65,000; of Guayaquil at 45,000; of Cuenca at 25,000; of Riobamba, 12,000; and of Ambato, Loja, and Latacunga about 10,000 each. A fire destroyed half the city of Guayaquil in 1897.

*Constitution.*—The Constitution in force is that of 1884, with modifications introduced in 1887 and 1897. The legislative authority is vested in a Congress of two chambers, the Senate consisting of 30 members (2 for each province), and the Chamber of Deputies with 41 members (1 for every 35,000 inhabitants, and 1 more if there are still 15,000 unrepresented). Senators are elected for four years, and Deputies for two, directly by popular vote, every male citizen who can read and write being an elector. Congress meets every second year at Quito on 10th June for a session of 60 days. The executive authority resides in the

President of the Republic, elected for four years by direct vote of the people, and not re-eligible till the two following presidential terms have elapsed. The Vice-President is elected two years after the President, and is therefore a member of two distinct administrations. He succeeds for the remainder of the term in case of the decease or disability of the President, and is, moreover, President of the Council of State. The President is assisted by 4 Secretaries of State, heads of departments, appointed by himself, and by a Council of State consisting of the Vice-President of the Republic, the 4 Secretaries, the Fiscal Minister, 2 Senators, 1 Deputy, 3 private citizens, and an ecclesiastical functionary, the last 5 members being chosen by Congress. This Council must be consulted by the President on every important measure or appointment. The President has the power of veto over measures passed by Congress; but if these measures are again voted, he has no other alternative than to accept them. The President cannot dissolve Congress or shorten their sittings within the two months established by law, but he can call an extraordinary session for a specified purpose. By a decree issued in 1896 the Indian population is exempted from payment of tribute and admitted to rights of citizenship. The provinces are administered by governors, nominated by the supreme Government; the departments by *jefes politicos*, or political chiefs; and the municipalities by *tenientes politicos*, or political lieutenants. The Galapagos Islands are under a *jefe territorial*, or territorial chief.

The subdivisions of the provinces, the cantons, and the parishes are administered by subordinate officials, all of whom are appointed by the President.

*Justice.*—The judicial power rests with a Supreme Court, composed of six judges and a fiscal judge nominated by the executive; a *Tribunal de Cuentas* of four members; six superior courts; tribunals of the second and third instance for commercial cases; and courts of consular judges at Quito, Riobamba, Cuenca, Guayaquil, and Monte Cristi; magistrates are appointed in each provincial capital; municipal *alcaldes* at the headquarters of each department; civil magistrates in all parishes. *Tribunales de Jurados* exist in Ibarra, Quito, Loja, Latacunga, Ambato, Riobamba, Cuenca, and Guayaquil for the trial of such criminal cases as the law brings within their jurisdiction. The judges of the Supreme Court, the six superior courts, and the members of the *Tribunal de Cuentas* are elected by Congress for a term of six years. The laws of Ecuador are founded on Spanish law, and are all written and codified. There is a civil code, a code of civil procedure, a commercial code, a penal code, and a code of procedure in criminal cases. Constant complaints are heard of the inefficiency and dilatory method of procedure in the courts of Ecuador, and apparently with much justification.

*Religion.*—According to the Constitution, "the religion of the Republic is the Roman Catholic Apostolic, and all others are excluded," but as a matter of fact official toleration exists for all forms of religion. In 1889 the tithes from which Church revenues had been collected were abolished, and instead a tax of 3 per 1000 on real estate was imposed.

*Education.*—Primary education is free and nominally compulsory. No great effort is, however, made by the authorities to compel the attendance of children. Under President Flores, from 1888 to 1892, much attention was paid to the question of public instruction, and many new establishments were opened. The number of primary schools is 1088, and in these 1498 teachers are employed. The number of pupils on the rolls in 1898 was 68,380. The National Government supports 778 schools, 452 for boys and 326 for girls, the remainder being maintained by the municipalities or from private sources. There are 35 schools for secondary and 9 national colleges for higher education. Colleges for the higher education of women are established at Quito, Guayaquil, Cuenca, Loja, and Latacunga, under the supervision of religious orders. In Quito is a central university with 32 professors and attended by 216 students in 1897. There are also university corporations at Guayaquil and Cuenca. The faculties include philosophy and literature, jurisprudence, medicine and pharmacy, and science. Theology is taught in seminaries for the education of the priesthood, three of these institutions being situated at Quito, and one in each diocese of the Republic. Commercial and technical schools have also been established at Guayaquil and Quito. There is a national library at Quito, containing 13,000 volumes, amongst them many old and rare books and manuscripts. The National Government devotes about 600,000 *sucrés* annually to educational purposes.

*Defence.*—The army consists of 221 officers and 3120 non-commissioned officers and men. The National Guard nominally contains a total strength of 95,329 men. The navy consists of 1 transport, 1 small gunboat, and 1 torpedo launch, these vessels mounting in the aggregate 9 guns. The ships are manned by 114 sailors.

*Finance.*—Of the revenue, about 70 per cent. is derived from import duties, 8 per cent. from export duties, 15 per cent. from taxes on cocoa, real estate, rum, and tobacco, 6 per cent. from the salt and gunpowder monopolies, and the remainder from excise, state property, and the post office. The chief spending departments are those of Public Works, Finance, War, and Education. From 19th June 1895 to 31st July 1896 the ordinary revenue (the *sucré* being taken at 24d.) amounted to £512,860, and the extraordinary receipts (mostly loans from banks) to £373,070; while the total expenditure amounted to £877,950. For 1897 the revenue was stated to amount to £676,055, and the expenditure to £569,020. For 1900 the revenue was estimated at £826,810 and the expenditure at £896,780. The external debt originally consisted of liabilities taken over by the Republic on its secession from Colombia. In 1855 the debt was fixed at £1,824,000, and arrangements were made for the payment of interest. In 1868 default was made. In 1892 the debt was converted into a New Consolidated Debt of £750,000, but in 1894 payment of interest was suspended. In 1895 a new arrangement was made which was suspended in 1896. In 1897–1900 various contracts were signed whereby the Guayaquil and Quito Railway Company was to purchase the bonds of the existing debt, the Government guaranteeing the sum of £2,520,000 mortgage bonds of the company, and recognizing the external debt at 35 per cent. of its face value. The internal debt is stated to be about 10,000,000 *sucrés*; its service is attended to irregularly.

*Industry.*—Industrial development has not made any marked progress, owing largely to the absence of transport facilities throughout the interior. Cocoa is the most important product, and is cultivated on the lower lands, especially in the neighbourhood of the Guayaquil river. In 1895 the receipts of this article at Guayaquil amounted to 16,122 tons; in 1896 to 15,327 tons; in 1897 to 14,800 tons; in 1898 to 19,000 tons; and in 1899 to 23,200. Though the cultivation of coffee has been considerably extended, low prices have greatly discouraged the planters. In 1897 the amount exported was 1201 tons, and in 1898, 1692 tons. Sugar is grown and manufactured principally for local consumption. The total export of sugar in 1898 was less than 2500 tons. The collection of india-rubber from the forests of the interior has increased, the amount shipped abroad in 1898 being 429 tons, as compared with 271 tons in 1897. In the province of Tungurague some 200 acres are under vines, from which a small quantity of wine is made, but the bulk of the grapes are sold fresh. Tobacco is also produced on a small scale for home use, the centre of this industry being in the province of Esmeraldas. Pastoral industry is confined to breeding cattle to meet the home demand for meat. The export of hides was valued at £27,060 in 1898. Ivory nuts were shipped to the value of £23,080 in 1898. Mining industry is practically confined to the work of gold quartz crushing at Zaruma, in the province of Loja, and to extraction in Esmeraldas from gravel beds by hydraulic process by American companies. Gold washing in the beds of rivers and streams is practised by the Indians. Petroleum exists in different localities, but no serious attempt has been made to work this natural product, nor has any development in mining for copper, iron, lead, or coal taken place, although large deposits of these minerals are stated to be found. Silver is found in considerable quantities in the province of Cuenca, and quicksilver in that of Loja. Manufacturing industry is represented by factories for soap, chocolate, biscuits, and vermicelli and macaroni; 4 sawmills; some small woollen and cotton mills; and a brewery and ice factory at Guayaquil. The making of straw hats, known as "Panama," is a national industry, the value exported in 1898 being £8900.

*Commerce.*—The foreign trade passes almost exclusively through the port of Guayaquil. The value of the imports and exports for 1890, and for the years from 1894 to 1900, is returned as follows:—

| Years. | Imports. | Exports. | Years. | Imports. | Exports. |
|---|---|---|---|---|---|
| | £ | £ | | £ | £ |
| 1890 | 1,001,635 | 976,164 | 1897 | 930,000 | 1,217,630 |
| 1894 | 1,200,000 | 1,393,375 | 1898 | 910,000 | 1,257,930 |
| 1895 | 852,000 | 1,156,274 | 1899 [1] | —— | 2,142,025 |
| 1896 | 870,000 | 1,088,920 | 1900 | 1,341,688 | 1,541,922 |

[1] The statistics of imports for 1899 were in great part destroyed by the fire at Guayaquil on 27th November 1899.

The imports consist mainly of cotton and woollen fabrics, provisions, flour, hardware, wines and spirits, and other articles of consumption or common use. The staple article of export is cocoa, of which there were shipped abroad in 1895, 32,516,000 lb; in 1896, 33,909,000 lb; in 1897, 33,123,000 lb; in 1898, 35,036,000 lb; in 1899, 47,704,550 lb. Of the shipments in 1899, 22,186,190 lb went to France; 5,535,310 lb to Spain; 9,781,720 lb to Germany; 5,493,100 lb to Great Britain; 3,473,220 lb to the United States; 1,235,010 lb to other countries. The exports will probably increase, since millions of new plants are planted every year. Other articles of export have been already mentioned. Of the imports, about 33 per cent. in value are from Great Britain, 15 per cent. from Germany, 15 per cent. from the United States, and 14 per cent. from France. The imports from Ecuador into the United Kingdom in 1899 (according to British statistics) amounted to £175,500, of which £154,960 was for cocoa; while the exports to Ecuador from the United Kingdom amounted to £403,425, of which £253,640 was for cotton goods. According to American statistics, the Ecuadorian imports into the United States in the year 1899–1900 amounted to the value of $1,524,375 (£304,875), and the United States exports to Ecuador to the value of $1,216,005 (£243,201).

*Shipping.*—Guayaquil, the principal port, is in regular communication not only with other Pacific ports, but with New York, Liverpool, and Hamburg. The coasting trade is carried on by small vessels under the Ecuadorian flag. Of vessels in the foreign trade in 1898, 206 of an aggregate tonnage of 298,805 entered and 200 of 290,855 tons cleared at the port of Guayaquil. Of those that entered, 110 of 162,280 tons were British. At the same port there entered also 3600 vessels of 34,989 tons engaged in the coasting trade.

*Communications.*—Roads are nothing better than mule tracks, over which wheeled vehicles cannot pass. The highway of 115 miles between Guayaquil and Quito is constantly in need of repair, bridges and culverts being frequently washed away. The navigation of the rivers Guayas, Daule, and Vinces is carried on by a fleet of 17 steamers, and by small craft and canoes. The only railway is that—with a gauge of 36 inches—from Duran, near Guayaquil, to Chimbo, a distance of 58 miles. A concession has been granted to an American syndicate to take over the line and prolong it to Quito. The total length of telegraph lines open to public service in 1898 was 1242 miles, with 60 offices. The principal cities are connected with Quito, and that city with Guayaquil. From Guayaquil there is cable connexion with the rest of the world. The telephone is in use in Guayaquil and the vicinity. The inland postal correspondence is stated to comprise about 850,000 letters annually, and the foreign correspondence about 1,809,000 letters and 6,347,000 newspapers and parcels.

*Money, Weights, and Measures.*—The monetary unit is the silver *sucré* of 100 cents, weighing 25 grammes, and ·900 fine. The *sucré* derives its name from President Sucré, a prominent figure in the War of Independence with Spain. Other silver coins are 50-, 20-, 10-, and 5-cent pieces. There are nickel coins of 5-, 1-, and ½-cent pieces, and bronze coins of 2 cents and 1 cent. By an agreement between the banks and the commercial community a rate of exchange equal to 10 *sucrés* to £1 was sustained during 1898, and still continues, with slight variations. Congress has recently provided for the coinage of gold pieces of the same weight and fineness as the British sovereign; these will be known as *condores*, each *condor* being equal in value to 10 *sucrés*. The British sovereign is also declared by this measure to be legal tender for the same value as the *condor*.

The principal banks within the republic are the Banco del Ecuador and the Banco Comercial y Agricola. The former has a capital of 2,000,000 *sucrés*, the latter one of 500,000 *sucrés*. Both issue notes, the banking law providing that one-third of the value of the issue must be held in coin, one-half of the reserve being in gold. On December 31, 1898, the note issue of the Banco del Ecuador was 2,138,170 *sucrés*, and that of the Banco Comercial y Agricola 3,522,242 *sucrés*. There are also two mortgage banks, the Banco Hipotecario and the Banco Territorial. The rate of interest charged is from 8 to 12 per cent. per annum. By the law of 6th December 1856 the metric system of weights and measures is the legal system of the republic, but the old Spanish weights and measures are almost invariably used.

*Recent Political History.*—After the assassination of President Moreno at Quito, in August 1875, Dr Borrero was elected to the presidency, but his tenure of power was short. A revolution headed by General Veintemilla, the Radical leader, then military commandant at Guayaquil, broke out in 1876, and on 14th December of that year the Government forces under General Aparicio were completely routed at Galte. Veintemilla was proclaimed president, and in 1877 was duly elected by the Cortes. He altered the constitution in a more Liberal direction, and struck various blows at the Clerical party, among other things abolishing the concordat with Rome. In 1878 Veintemilla caused himself to be declared elected as president for a term of four years. At the expiration of this period the president assumed dictatorial powers and remained in office as chief of the executive. This action on the part of General Veintemilla led to a union between the Clericals and Moderate Liberals, and resulted in a popular rising throughout the republic, ending in his defeat and overthrow. His power was first restricted to Guayaquil and Esmeraldas, and finally General Rinaldo Flores drove him from Guayaquil, and Veintemilla fled (July 1883) to Peru. Dr Placido Caamaño was then called upon to take charge temporarily, and on 17th February 1884 was definitely elected for the presidential period terminating in 1888. Several revolutionary outbreaks occurred during the Caamaño administration, but were successfully suppressed. In 1888 Dr Antonio Flores succeeded Caamaño, the four years following being passed in peaceful conditions. In 1892 Dr Luis Cordero was elected, his administration again plunging the country into an epoch of internal disturbance.

The cause of the troubles under President Cordero was the assistance lent by Ecuador to Chile in the matter of the sale of the cruiser *Esmeralda* to the Japanese Government in 1894, in the middle of the Japanese–Chinese War. The Government of Chile arranged the sale of the *Esmeralda*, but wished to be free from all danger of international complications in the affair. To this end the transfer of the vessel was made to Ecuador, and she proceeded to Ecuadorian waters. On arriving at the Galapagos Islands the flag of Ecuador was replaced by that of Japan and the vessel handed over to the representatives of that nation sent for the purpose. When the part played by President Cordero in this transaction became known, an outburst of popular indignation occurred. An insurrection, headed by General Eloy Alfaro, followed; and after desultory skirmishing extending over a period of nearly a year the Government forces were finally routed, President Cordero abandoning his office and escaping from the country.

General Alfaro then assumed dictatorial powers as supreme chief of the nation, continuing in this capacity until 6th February 1897, on which date he was declared to be elected president of the republic. A series of revolutionary movements against the administration of President Alfaro occurred in the course of the next few years. Many of these risings were due to the intrigues of the Church party, and in view of these circumstances President Alfaro curtailed the influence of the clergy in several directions. On 31st August 1901 General Alfaro peacefully handed over the presidency to his elected successor, General Plaza.

(W. W. R.; C. E. A.)

**Edessa,** now called Urfa, one of the most important towns of Northern Mesopotamia. It stands at a height of 1700 feet above sea-level, on the right bank of the Scirtus (Syrian, *Daiẓon*), a winter torrent which discharges into the Belikh, a tributary of the Euphrates. Urfa is the capital of a sanjak of the same name, in the Aleppo viláyet, seat of a governor and of an Armenian bishop, situated on the border of a fertile plain noted for its wheat and fine pasture, on the great caravan road from Aleppo to Mosul, about 46 miles east of Birejik. It stands partly on the plain and partly on two rocky hills, between which runs a small stream. There are remains of the old walls, with their rock-hewn ditch, and of the citadel. The streets are narrow and winding, with well-built stone houses. Beneath the citadel are two springs, which supply tanks—one the Birket Ibrahím, with sacred fish, now under the protection of Abraham, as they formerly were under that of Atergatis. About one mile from the town is a spring connected by tradition with the healing of Abgar's leprosy by Thaddeus. The climate is healthy, but not in summer: the "Aleppo button" is common. The principal manufactures are fine cotton stuffs and yellow leather. The population numbers 20,000 (Moslems 8500, Armenians 7500, Syrians, Greeks, Protestants, and Jews 4000). On the 28th and 29th December 1895 there was a barbarous massacre, between 3000 and 4000 Gregorian, Roman Catholic, and Protestant Armenians perishing.

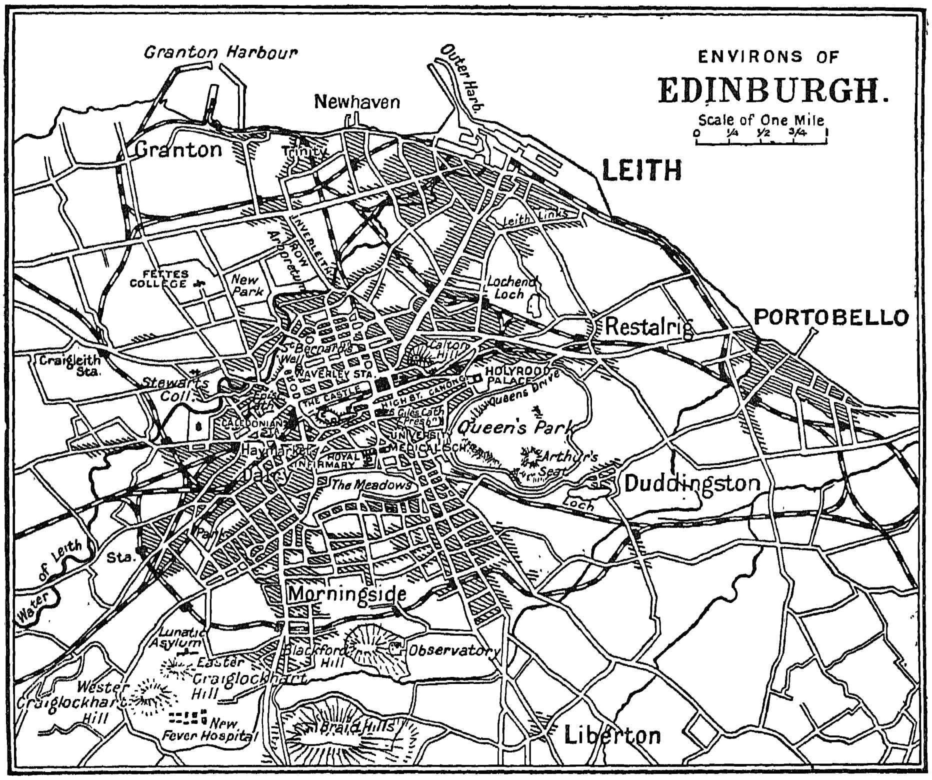
**Edinburgh,** a city, county, and parliamentary burgh, and the capital of Scotland, situated on the south shore of the Firth of Forth, and surrounded by the county of Midlothian, 396 miles by rail north of London, with which it is connected by the Great Northern, Midland, and London and North-Western Railways. Its progress since 1880, if not so rapid as that of some other towns more dependent for their prosperity on trade and manufactures, has been steady and great.

*Area.*—Its area has been enlarged by successive extensions of its municipal boundaries, especially towards the west and south, the directions in which growth has been most marked. An important accession of territory was obtained in 1896, when portions of the parishes of Liberton and Duddingston and the police burgh of Portobello were incorporated in the city. The attempt then made to secure the amalgamation of the contiguous burgh of Leith to the Scottish capital did not prove successful. Under the Edinburgh Corporation Act, 1900, a further addition of nearly 1800 acres was made to the city area. This embraces portions of South Leith parish (landward) and of Duddingston parish, including the village of Restalrig and the ground lying on both sides of the main road from Edinburgh to Portobello; and also part of Cramond parish, in which is contained the village and harbour of Granton. The total area of the city is now 10,597½ acres.



*Population and Wealth.*—The number of inhabitants, set down at 212,729 in 1877, increased to 234,402 in 1881, to 261,225 in 1891, and to 316,479 in 1901. In 1900 the birth-rate was 26·90 per thousand of population, 7·8 per cent. of the births being illegitimate; the death-rate, 19·40 per thousand of population, and the marriage-rate 10 per thousand. Of the total number of deaths 29 per cent. were those of children under five years, compared with 39·8 per cent. in Glasgow. The increase in wealth may best be measured by the rise in the assessed valuation of the town. The city rental was £1,727,740 in 1880, £2,106,395 in 1890, and £2,807,122 in 1900–1901.

*Municipal Government and Finance.*—There have been corresponding growth and change in the municipal and political organization of Edinburgh. By the Redistribution Act of 1885 the number of the city's representatives was doubled, and it was divided, for electoral purposes, into East, West, Central, and South Edinburgh, each returning a single member; the parliamentary and municipal boundaries have been made almost coterminous. The parliamentary constituency in 1901 numbered 42,375 registered electors, of whom 11,025 were in the East, 8926 in the West, 7630 in the Central, and 14,794 in the South divisions. The municipal constituency is 59,339. The Town Council has been increased to fifty members, and consists of a Lord Provost, 7 bailies, a dean of guild, treasurer, and convener of trades, 7 judges of police, and 32 ordinary councillors. Among the important new public duties and functions undertaken by the Corporation and its dependent bodies may be mentioned the acquisition of the gas-works, and of the horse and cable tramways; the electric lighting of the streets; the bringing in of an additional water supply from the Moorfoots, to be supplemented by the Talla Water scheme; and the purchase of

several public parks, including the Braid Hills and Blackford Hill.

*Finance.*—The debt of the city at 15th May 1900, existing and in immediate prospect, amounted to £3,515,585, made up as follows:—To be met out of the rates, £1,623,440; tramways, £1,147,817; electric lighting, £652,078; municipal debt to be met out of Common Good revenue, £92,250. The estimated net expenditure of the city, under the Municipal and Police Acts, for the year ending 15th May 1901, was £331,365, of which £303,098 was chargeable on the burgh assessment. The rates imposed for 1900–1901 were at 9½d. per £ on owners and 1s. 8¼d. per £ on occupiers, together 2s. 5¾d. per £, being the same as the rates imposed in the preceding year. The estimated capital expenditure contemplated on schemes sanctioned by the Council includes the sums of £116,000 on the improvement of the City Chambers, £57,000 for the purchase of the new park at Saughton, £193,000 for the erection of the new City Hospital, and £153,000 for acquiring and demolishing old property and erecting new houses on "Dwelling-House Improvement" account.

*Industries.*—Many new branches of industry have been started; and the older industries, like printing and brewing, for which the town has long been celebrated, have received further development. But Edinburgh is still, as it was in 1875, and as it has been during its recorded history, a residential rather than a commercial or manufacturing city. City improvements, some of them still in progress, have swept away, as "slum property," numerous buildings of venerable age and historic associations. Along with this inevitable process of change there has gone, however, an effort not only to preserve ancient and characteristic features of the street architecture of the Old Town, but to rescue from degradation, and to restore something of their long-lost social dignity to, the closes and front "lands" of the Lawnmarket, the High Street, and the Canongate. If the city is no longer, in the same sense as early in the 19th century, the home and centre of literary society, it can still claim to be a place whose main industry is education, which, whether as regards its University and Medical School, its secondary, technical, and endowed institutions, or its public elementary schools, has undergone immense development since 1875.

*The Castle.*—The Castle, which from its rock has always dominated the site and history of Edinburgh, has received a number of improving and restoring touches. The most important of these was due to the late Mr William Nelson, publisher, who, by his restoration of the Argyll Tower and of the Old Parliament Hall, furnished but one of the many instances of local patriotism and private munificence exhibited during their lifetime by citizens on behalf of the amenities and institutions of the town. The Parliament and Banqueting Hall forms a lofty, spacious, and beautiful hall of arms, with a fine collection of Scottish armour and weapons and old regimental colours, and the heraldic bearings of royal and distinguished figures in national history emblazoned on the windows overlooking the Grassmarket. A new hospital, in the Scottish baronial style, has also replaced the former ugly structure.

*Holyrood.*—The neglected and dilapidated royal vault in the Chapel Royal has been repaired and put in order. Clockmill House and grounds have been added to the area of the parade ground, and there have been improvements in the Abbey precincts and in the accesses to the King's Park. The privileges of sanctuary came to an end with the abolition of imprisonment for debt in 1881.

*Old Town Improvements.*—Time and the city improvements have laid heavy hands on the Old Town buildings. Other agencies that have been active in producing change have been railway extension and the necessity for forming new or widening old streets. Much that was ancient and interesting has had to yield place to the requirements of sanitation, social progress, and public convenience. On the other hand, it has been found possible in many cases to increase the amenity of the main thoroughfares and the closes of "Auld Reekie," while preserving, and even enhancing, the picturesque features of its architecture. The Canongate quarter has suffered comparatively little alteration. New buildings have arisen, however, in the Watergate and Horse Wynd, and in the North and South Back of Canongate. The Old White Horse Close has been tastefully renovated; a public board school has taken the place of Milton House, traditionally associated with Cromwell's residence in Edinburgh; New Street, a town improvement of more than a century ago, and the home of eminent men in law and letters of a past generation, has disappeared in the course of railway alterations. Much change has taken place in the vicinity of the Netherbow, where formerly the bounds and authority of the city met those of the Canongate. St Mary Street, the former "Rag Fair" outside the town wall, has been almost rebuilt; it was the first-fruits of the labours of the Improvement Trust. Jeffrey Street has supplanted what was once Leith Wynd, and is continued westwards in Market Street, which fronts the railway line with many handsome buildings, including the new Trinity College Church. In the place of the historic Blackfriars Wynd there is a new and prosaic thoroughfare; and "Beaton's Palace," the old Cunzie House, and other ancient dwellings have been removed from the adjoining Cowgate. Much more significant and more important are the changes produced by the rebuilding of the North Bridge. The bridge has been widened and heightened, and at its northern end, opposite the General Post Office, the North British Railway Company have built a magnificent new hotel. To make way for the lofty and handsome block of buildings fronting the new North Bridge Street on the east side, many old houses have been pulled down, including Robert Fergusson's birthplace in the Cap and Feather Close, and Allan Ramsay's wigmaker's shop, "at the sign of the Mercury, opposite Niddry Wynd." As great a sweep of ancient landmarks has been made on the other side of the thoroughfare, where the new and stately *Scotsman* buildings occupy the site of the many famous drinking "howfs" of the Fleshmarket Close and Milne's Square. In the part of High Street between the Tron Church and Parliament Square an important city improvement has involved the demolition of a host of noteworthy sites and dwellings in Stevenlaw's, Burnet's, Covenant, and Assembly Closes, all these narrow and unwholesome alleys being now opened to the air and light. The extension of the Municipal Buildings in Writers' Court and Warriston Close has caused the destruction of Clerihugh's tavern, the scene of the "high jinks" described in *Guy Mannering;* and the earlier improvement of opening St Giles Street, beside which stands the new Bank of Scotland, caused another great breach in the ranks of the old High Street houses. Opposite, at the corner of High Street and George IV. Bridge, the County Buildings, erected in 1818, will be replaced by a more commodious structure. Among the improvements and additions made on the adjoining Parliament House may be mentioned the Library of the Solicitors before the Supreme Courts, which presents to the Cowgate a lofty elevation in red sandstone. The Sheriff Court Buildings and the new Free Library also rise out of the depths of that hidden thoroughfare, and face each other on the higher level of George IV. Bridge. The latter structure is the gift to the city of Mr Carnegie, and cost £50,000. The Lawnmarket, the West Bow, and the Castle Hill bear many traces, in frontages and recesses, of change tempered by taste. The congeries of alleys on the north side of the Lawnmarket, from Paterson's Close to James Court, have been cleansed and connected; and here Lord Rosebery has acquired and restored the 17th-century dwelling in which was located the legend of "My Aunt Margaret's Mirror." Another model restoration of a historic Edinburgh close is found across the way in Riddle's Court, converted into a "University Hall." Quaint examples of Lawnmarket and Bow Head tenements have disappeared, partly through the extension of the Free Church Assembly Hall; a board school has usurped the place of the old Gordon mansion on Castle Hill; while a new and noteworthy addition has been made to the architectural features and the social amenities of this part of the Old Town by the development of Allan Ramsay's former residence of Ramsay Lodge into the imposing group of Ramsay Gardens.

*The University, &c.*—The "youngest of the Scottish universities" has continuously maintained and enhanced its reputation as a seat of learning, and more particularly as a medical school; and it has increased in wealth, in equipment, and in the number of its students, which in 1899–1900 reached 2789, compared with 2065 in 1875–6. The constitution, administration, and curriculum of the university have undergone great development, the most recent changes taking place under the Act of 1889. In 1883 it celebrated its tercentenary; it was one of the first universities to admit women students to its classes and degrees; and its alumni have been brought into closer bonds of sympathy and action by the formation of a handsomely housed Students' Union. The university buildings have received extension and embellishment to meet the needs and tastes of the age. The plan of the structure, designed by Adam and Playfair, has been completed by a dome and cupola crowning the façade in South Bridge Street; the opening up of the spacious thoroughfare of Chambers Street, on the site of College Wynd and Brown and Argyll Squares, has cleared the precincts of the old university buildings of unsightly obstructions and unsavoury neighbours; the Museum of Science and Art, structurally united to it, has been completed and enriched with additional collections illustrative of industry, art, and natural history; and opposite have arisen other new structures, the Minto House Medical College and the Heriot-Watt College, which may be regarded as adjuncts of the university. Within, the library hall has received restoration and decoration, largely through the generosity of Sir William Priestley, formerly member for the university; while munificent additions to the academic funds and resources have been made by the late Earl of Moray, Sir William Fraser, Mr John Usher, and others. The University will benefit also, like the other Scottish Universities, from Mr

Carnegie's noble endowment fund. The most splendid evidence of its growth and of the liberal and enlightened spirit in which it is supported is provided by the new Medical School, built in Teviot Row, adjoining George Square and the Meadows. To this fine and spacious group of buildings the Faculty of Medicine has been removed; and its suite of class-rooms, operating theatres, and laboratories equip it thoroughly for its work of teaching and healing. The Medical School is in the Renaissance style, from the designs of Dr Rowand Anderson, and when completed by a campanile tower will have cost over £300,000. A magnificently decorated hall, for academic and other public functions, is the gift of Mr William M'Ewan, M.P., to the university and city, and with the grand organ has cost a sum of £115,000. Closely associated with the Medical School, and separated from it by the Middle Meadow Walk, is the Royal Infirmary, removed hither from Infirmary Street. Its wards, in which nearly 10,000 patients receive treatment annually, are lodged in a series of turreted pavilions, and cover a large space of ground on the margin of the Meadows, from which, to make room for it, George Watson's College—the most important of the Merchant Company schools—has had to shift to a site farther west, while the Sick Children's Hospital has moved to the farther side of the Meadows. The Old Infirmary buildings have served the purposes of a City Fever Hospital, which soon, however, will be accommodated more spaciously and suitably on a site lying on the burgh outskirts at Wester Craiglockhart Hill. Similarly, the Royal Edinburgh Asylum for the Insane has been crowded from its old ground at Morningside, and has occupied a noble structure set on a commanding position on the easter hill of Craiglockhart; and the Royal Blind Asylum has moved from its former quarters in Nicolson Street to a new home at Powburn. A Home for Incurables has been erected in Salisbury Place. Among the host of benevolent, charitable, and other public institutions mention may be made of the Central Public Baths in Infirmary Street, and branch establishments in other parts of the town, including the new suburb of Portobello, and the Workmen's Institutes planted in crowded districts of the city with funds provided by the late Mr Thomas Nelson.

*Endowed and Public Schools.*—Among buildings more strictly educational in their purposes, notice must be taken of the host of new public schools, for the most part large, handsome buildings, which bear witness to the zeal and activity of the School Board in providing for the elementary and advanced instruction of the young, and fulfilling their other duties under the Act of 1872. A large number of these schools have been erected within the city bounds, and the expenditure of the board on building, including sites, and exclusive of schools now being built, has been £496,000. The estimated expenditure on two new schools which are approaching completion, and for additions that are being made to other schools, is over £73,000; and plans have been prepared for a new school for the Craiglockhart district, in the south-west of the city, at a probable cost of £30,000. Two of the existing schools have been graded and fitted with apparatus to meet the requirements of the secondary education grant, and a day industrial school for truant children has been provided. The new Merchant Company colleges have more than fulfilled the expectations of those who devised the scheme by which the buildings and endowments founded on the old "hospital" system, were devoted to the purpose of establishing highly-equipped day schools, which should carry the pupils through all the stages of primary and secondary education. In this way George Watson's College, Stewart's College, and the Queen Street Ladies' College, George Square Ladies' College, and Gillespie School, possessing an aggregate income of £66,000, have taken a high place among the educational institutions of the city and country, and have become important feeders of the university. The Heriot Trust, also, has devoted its funds, now reaching over £30,000 annually, mainly to the encouragement of secondary, technical, and higher education; in addition to the support thus provided for the Heriot-Watt College already mentioned, the fine and venerable structure of Heriot's Hospital is occupied as a technical school, and a large part of the revenue is spent on a school and university bursary scheme. The Royal High School—the old and famous burgh school of Edinburgh—has also been reorganized and enlarged to meet modern requirements; and on the northern outskirts there has risen in Fettes College—an endowed institution on the model of the English public schools—an architectural ornament of the city.

*New Town Improvements.*—The New Town has spread westwards and northwards in handsome streets, terraces, and crescents, which in both directions have crossed over the valley of the Water of Leith. By the purification of the stream, carried out at the cost of the city, a great addition has been made to the amenity of its neighbourhood, which has been further increased by the restoration and embellishment of St Bernard's Well and its surroundings, an improvement of which the whole cost was borne by the late Mr William Nelson. Beyond the Water to the north, between Inverleith Row and the Fettes College grounds the Arboretum, joined on one side to the Royal Botanic Gardens, and adjacent on the other to the new Inverleith Park, has become a favourite public resort. To the south and west of Haymarket a populous working-class district has sprung up at Dalry. In Atholl Crescent is a possible site of a public hall for musical and other purposes, for which the late Mr Thomas Usher gave the sum of £100,000. Important changes have been made upon the architectural appearance of Princes Street, George Street, St Andrew Square, and the adjoining thoroughfares, through the erection of new hotels, banking and insurance offices, and clubs; and at the east end of Queen Street a stately structure, designed by Dr Rowand Anderson, to accommodate the National Portrait Gallery and the Antiquarian Museum, has been raised through the liberality of the late Mr J. R. Findlay of Aberlour, who bestowed a sum of nearly £70,000 for the purpose, the Government providing the site. In Castle Terrace the Synod Hall of the United Presbyterian Church (now joined to the Free Church, under the title of the "United Free Church of Scotland") is flanked on either side by the School Board and Parochial Board offices; while behind it, in Grindlay Street, is the Lyceum Theatre.

*Churches.*—The most important addition made in recent years to the churches of Edinburgh is St Mary's Cathedral, belonging to the Scottish Episcopal Church. It is built on ground and chiefly from funds bequeathed by the late Miss Walker of Coates, and the Cathedral Close contains the early 17th-century mansion of East Coates, now occupied by the organist, and a Song School. The church, designed in the Early Pointed style by Sir Gilbert Scott, is 278 feet in length, and is surmounted by a spire 275 feet in height. A chapter-house has been added by the late Mr Hugh Rollo, and when the two western towers are completed the whole cost of the edifice will be some £140,000. Many other churches, of different denominations, have been built or rebuilt in the city and suburbs, the most noticeable, from an architectural point of view, being perhaps the Catholic Apostolic church at the foot of Broughton Street, one of the features of which is a fine set of mural paintings executed by Mrs Traquair. In all there are now 192 places of worship in the city, of which 46 belong to the Church of Scotland, 75 to the United Free Church and 4 to the other Presbyterian churches, and 26 to the Episcopalian, 7 to the Roman Catholic, and 34 to other denominations.

*Railway Improvements.*—Among the most important of the city changes are those that have taken place in the hollow between the Old and New Towns. The increase in the traffic of the North British Railway has rendered necessary successive alterations and enlargements of the Waverley Station, which will become one of the most extensive, as regards platform area and other accommodation, in the country. Additional tunnels of access have been formed from Haymarket on the west and Abbeyhill on the east; and it has been found necessary to appropriate strips of the East and West Princes Street Gardens. The Caledonian Railway, also, has built a handsome and commodious new station, with hotel attached, at the west end of Princes Street; and among the additions to the railway mileage of the city and its vicinity are the Caledonian branch lines to Leith and Cramond Bridge, and the suburban and Corstorphine lines of the North British Railway.

*New Parks and Monuments.*—Edinburgh is well provided with "lungs," in the shape of public parks. In addition to the magnificent open spaces previously existing within the city bounds, in the King's Park, the Meadows, the Calton Hill, the Princes Street Gardens, &c., a large area of new ground has been set apart of late years for the health and recreation of the citizens. Mention may be made of the Blackford Hill, on the shoulder of which the new Royal Observatory has been built and the great Dunecht telescope fitted up. Beyond is another spacious and breezy playground, the Braid Hills, mainly devoted to the game of golf. These are on the south side of the city. On the north of the Water of Leith are the Arboretum and Inverleith Park. The Harrison Park provides recreation ground for the dwellers in the crowded district around Fountainbridge; and another and larger public park for the western district of the city has been purchased by the Town Council at Saughton Hall. The numerous monuments of Edinburgh have been reinforced by a statue of the late Duke of Buccleuch in High Street, of Dr Thomas Chalmers in George Street, of Dr Livingstone, Adam Black, and Sir James Young Simpson on the line of Princes Street, of John Knox in the quadrangle of the Free Church College, and Sir William Chambers in Chambers Street. (J. GE.)

**Edinburghshire,** or **Midlothian,** a county on the southern shore of the Firth of Forth, bounded on the W. by Linlithgow, on the E. by Haddington, and on the S.-W. and S. by Lanark, Peebles, Selkirk, Roxburgh, and Berwick shires. Geographically it embraces the city of Edinburgh (administratively a separate county) and the parliamentary burghs of Leith and Musselburgh.

*Area and Population.*—With regard to area, so many alterations have been, and are in process of being, made upon it by the extensions of Edinburgh city, and by alterations in the boundaries by the Boundary Commissioners under the Local Government Act of 1889, that it would be a matter of considerable difficulty to arrive at a correct statement of the present acreage. The geographical area is given as 362 square miles, or 231,724 acres. The county and parish changes of boundary in 1889 were chiefly in the parishes of Cramond and Fala, and involved small transferences of population and acreage from West Lothian and East Lothian to the county. The population of the registration county, including Edinburgh city, was 388,811 by the census of 1881, 433,552 in 1891, and 488,647 in 1901. Outside of the parliamentary burgh areas the figures were 75,120 in 1881, 81,033 in 1891, and 83,807 in 1901. The principal centres of population within the bounds of Midlothian are Edinburgh (municipal burgh, including Portobello), 316,479 inhabitants in 1901; Leith, 76,667; Musselburgh, 11,704; Dalkeith, 6753; Loanhead, 3011; Bonnyrigg, 2926; and Penicuik, 2803. According to the latest corrected figures, the percentage of births within the registration area was 2·91; of deaths, 1·67; and of marriages, 0·83. Illegitimate births formed 7·43 per cent. of the whole.

The following table gives particulars of births, deaths, and marriages in 1880, 1890, and 1899:—

| Year. | Deaths. | Marriages. | Births. | Per cent of Illegitimate Births. |
|---|---|---|---|---|
| 1880 | 8558 | 3016 | 13,255 | 7·3 |
| 1890 | 8909 | 3266 | 12,571 | 7·4 |
| 1899 | 8901 | 4290 | 13,485 | 6·3 |

The following table gives the birth-rate, death-rate, and marriage-rate per 1000 of population at different periods since 1880:—

| | 1880. | 1881–90. Average. | 1890. | 1899. |
|---|---|---|---|---|
| Birth-rate | 34·52 | 31·50 | 29·22 | 28·27 |
| Death-rate | 22·29 | 19·53 | 20·70 | 18·66 |
| Marriage-rate | 7·86 | 7·75 | 7·59 | 8·99 |

*Constitution and Government.*—The county, generally spoken of in this connexion as Midlothian, forms a single parliamentary constituency, exclusive of Edinburgh city and the Leith burghs. The parliamentary constituency in 1900–1 numbered 14,077; the valuation (including railways and water-works) was £674,842. Under the Local Government Act of 1889, the county is divided into 38 electoral districts, and these have been by the County Council arranged into 4 county districts for the purposes of the Roads and Bridges Act, 1878, and the Public Health Acts. The management of special districts formed for water supply, drainage, and other sanitary purposes is committed to sub-committees appointed by the respective district committees. The grant under the Local Taxation (Customs and Excise) Act is administered by the Technical Education Committee appointed by the Council; and on the same authority, a special committee, called the Secondary Education Committee, looks after the distribution of the grant under the Local Taxation (Scotland) Act.

*Education.*—There are in the county, exclusive of Edinburgh and the other burghs, 30 separate school boards, managing 96 schools, the average attendance in these being 16,394 in 1899–1900. The grant for higher education earned in 1899 amounted to £1588 16s. 4d.

*Agriculture.*—The depression in agriculture has not affected Midlothian so severely as some other counties; compensation for the fall in the price of grain and other agricultural products has been found in the growth of population and the local demand. There have been comparatively few changes in the size of agricultural holdings, either in the shape of cutting up large farms into small ones, or amalgamating small farms in larger. The neighbourhood of Edinburgh has given considerable stimulus to dairy-farming. The area under crops has increased rather than diminished, but the area under corn crops is nearly 6000 acres less than in 1880. Fallow land has practically disappeared.

| Year. | Area under Crops. | Corn Crops. | Green Crops. | Clover, &c. | Perennial Pasture. |
|---|---|---|---|---|---|
| 1880 | 134,344 | 38,628 | 21,365 | 29,390 | 44,703 |
| 1890 | 139,764 | 34,367 | 18,779 | 37,296 | 48,928 |
| 1899 | 132,833 | 33,033 | 19,354 | 32,813 | 47,279 |

Wheat, notwithstanding the fall in prices, may be said to hold its own among the grain crops; the area devoted to wheat, some 5000 acres, is rather larger than in 1880, and represents practically the whole acreage of arable land on which this crop can be profitably grown at present rates. Oats also maintain their ground on the whole; the great reduction has been in barley. The following are the figures for live-stock:—

| Year. | Total Horses. | Total Cattle. | Cows or Heifers in Milk or in Calf. | Sheep. | Pigs. |
|---|---|---|---|---|---|
| 1880 | 3979 | 18,907 | 10,765 | 170,562 | 5309 |
| 1885 | 4143 | 21,472 | 12,308 | 168,873 | 7141 |
| 1890 | 4415 | 22,404 | 12,623 | 179,565 | 6888 |
| 1895 | 4540 | 19,451 | 11,096 | 183,322 | 8133 |
| 1899 | 4478 | 21,450 | 12,537 | 191,403 | 8194 |

*Industries.*—There are few changes to note with regard to the staple industries of the county of Edinburgh. The paper-mills, situated chiefly in the valleys of the Esk and the Water of Leith, have increased their production while improving their processes. Near the outskirts of the city a number of new brewing, distilling, and other works have sprung up; on the other hand, some of the Midlothian granaries have been closed through exhaustion. The quantity of coal raised in 1900 was 1,329,495 tons; and 9160 men were employed at the collieries above and below ground. The production of oil shale was 637,810 tons. The county output of sandstone was 132,761 tons, and of limestone 177,696 tons. For the year 1900–1, the quantity of white fish landed in the Leith district was 207,218 cwts., valued at £133,895; there were 364,616 barrels of herrings, exported mostly to Germany.

**Edison, Thomas Alva** (1847-——), American inventor, was born 11th February 1847, at Milan, Erie county, Ohio, but his parents moved to Port Huron, Michigan, when he was seven years old. At the age of twelve he became a train news-boy on the railway to Detroit, and managed to gratify his youthful interest in chemistry by performing experiments while travelling. At fifteen he became a telegraph operator, and was employed in many cities in the United States and Canada, but frequently neglected his duties in order to carry on studies and experiments in electrical science. Before he was twenty-one he had constructed an automatic repeater, by means of which a message could be transferred from one wire to another without the aid of an operator; and he had also directed his attention to the problem of duplex telegraphy, of which he later invented a successful system. In 1869 Edison came to New York City, and soon afterwards became connected with the Gold and Stock Company. He invented an improved printing telegraph for stock quotations, for which he received $40,000. He then established a laboratory and factory in Newark, N.J., for further experiments and for the manufacture of his inventions. In 1876 he removed to Menlo Park, and later to West Orange, N.J., where he continued his experiments. Since then his name has been prominently associated with all kinds of novelties in practical electricity. Among his principal inventions are his system of duplex telegraphy, which he later developed into quadruplex and sextuplex transmission; his carbon telephone transmitter; the microtasimeter, for the detection of small variations in temperature; the phonograph, which records and reproduces

all manner of sounds; and his method of preparing carbon filaments for the incandescent electric lamp. In 1878 Edison received the degree of Ph.D. from Union College, and in the same year was made a chevalier of the Legion of Honour by the French Government.

**Edmonton,** a suburb of London, England, in the Enfield parliamentary division of Middlesex, 9 miles north of the City by rail. There is an ancient church containing interesting brasses and tablets, town-hall, and a free library. Cowper and Keats lived here for a time, as did Charles Lamb, who died and was buried here. In 1881 Southgate was separated from Edmonton parish. Population of urban district (3890 acres), (1881), 15,174; (1891), 25,380; (1901), 46,899.

**Edmunds, George Franklin** (1828——), American lawyer and statesman, was born in Richmond, Vermont, on 1st February 1828. He began the practice of law in 1849. He served in each House of the Vermont legislature at different times between 1854 and 1862, and was elected to the United States Senate in 1866, where he remained until 1891, when he resigned in order to have more time for the practice of his profession. He took an active part in the attempt to impeach President Johnson. He was influential in providing for the electoral commission to decide the disputed Presidential election of 1876, and became one of the commissioners. In the Republican conventions of 1880 and 1884 he was a candidate for the Presidential nomination. From 1881 until 1885 he was president *pro tempore* of the Senate. As senator he was conspicuous on account of his legal attainments, industry, and liberal opinions. He was the author of the so-called Edmunds Act of 22nd March 1882 for the suppression of polygamy in Utah.

# EDUCATION.

FORMER articles on the subject of education have appeared successively in the various editions of the *Encyclopædia Britannica*, and have well illustrated the very different aspects under which the subject of education may be viewed. Mr James Mill's treatise in the Supplement of 1824 discussed with fulness and much acuteness various abstract questions—*e.g.*, the genesis of ideas; the qualities of mind which it should be the chief business of education to develop; the instruments of instruction; the circumstances, whether material or moral, which operate upon and control mental growth; and the right function of domestic, social, and political training respectively, as distinguished from formal didactic teaching by means of school lessons. Except for a descriptive reference to Jeremy Bentham's famous experiment of a "Chrestomathic" day-school, there is little in Mr Mill's article which deals practically with the provision or organization of schools, or with any proposals for legislative action. The whole of this valuable paper is speculative and philosophical, and is highly characteristic of its author and of the spirit in which the subject of popular instruction was at first approached by the leading thinkers of his day. Dr J. D. Morell, one of the most distinguished of the first group of inspectors, contributed to the edition of 1858 an account of German and Swiss education, and a description of the tentative efforts which at that date the Government of Great Britain was making in the department of public elementary instruction. He foreshadowed with much ability the probable future of a State system in England on the lines laid down by Sir James Kay Shuttleworth—a system then in an early and experimental stage, and only beginning to attract the serious attention of British statesmen. Mr O. Browning's article in the ninth edition is mainly concerned with the growth of educational ideas and theories. He followed the precedent set by Aristotle, who in book i. of the *Metaphysics* made a critical survey of the history of Greek philosophy from Thales to Plato, and an estimate of the merits of the chief metaphysical writers. As a descriptive history of the books and speculations which all through the Greek, Roman, and Renaissance periods have in different ways helped to shape opinion and policy on the subject of education, Mr Browning's article is invaluable to the student who desires to take a *vue d'ensemble* of the several parts of the educational problem, and to know what are the ideals which have from time to time prevailed on this subject, and how far it has been possible to give practical effect to those ideals. Other branches of the general subject will be found treated in detail in the articles UNIVERSITIES and TECHNICAL EDUCATION. In connexion with each of the countries of Europe and of the British colonies and dependencies there will be found facts relating to the educational provision made by their several Governments, and the way in which the law of public instruction is administered. The scope of the present article is thus definitely restricted. Its main purpose will be to trace the gradual growth of what may be called the English system, the forces which have controlled it, and the results it effected during the last quarter of the 19th century.

***Characteristics of English educational history.***

It should be observed *in limine* that England has a unique history so far as public provision for the education of the people is concerned. That provision is not the product of any theory or plan formulated beforehand by statesmen or philosophers. It has come into existence through a long course of experiments, compromises, traditions, successes, failures, and religious controversies. What has been done in this department of public policy is the resultant of many diverse forces, and of slow evolution and growth, rather than of clear purpose and well-defined national aims. It has been effected in different degrees by philanthropy, by private enterprise, by religious zeal, by ancient universities and endowed foundations, by municipal and local effort, and only to a small extent by legislation. The genius, or rather the characteristic mental habit, of the English people, is averse from philosophical system, and is disposed to regard education not as a science, but as a body of practical expedients to be discovered empirically and amended from time to time as occasion may require. The tendency to distrust theorists and to be afraid of legislation has in England been strongly reinforced, and indeed largely justified, by the fact that most of the legal enactments of the past were negative and restrictive only, and were neither calculated nor intended to encourage educational progress. Henry VIII.'s ordinances respecting grammar schools forbade the use of any other than the authorized primers and Latin books. Elizabeth's Act of Uniformity severely restricted the liberty of teaching; and the Act of Charles II. in 1662 obliged all schoolmasters, whether lay or clerical, to accept the declaration of Conformity, and to obtain a licence from the bishop or the ordinary. The Acts generally known as the Clarendon Code were even more stringent in their requirements, and the Occasional Conformity Act (1711) and the Schism Act (1713) put it out of the power of Dissenters to hold office or to keep any private or public school. Thus the

efforts of later reformers were during many years directed rather to the removal of disabilities and hindrances than to the actual encouragement of education by legal measures. It was not till the year 1779 that the Act was passed rendering it lawful for any person to act as schoolmaster without subscribing the Thirty-nine Articles. The Test and Corporation Acts survived to the year 1829; and subscription to the Articles was enforced as a condition of taking degrees at the Universities until 1871. It has thus happened that the habitual attitude of the English people was for a long period marked by watchful jealousy and dislike of all legislative action. In fact, the evil memories associated with the harsh and intolerant legislation of an older time caused many Englishmen in the beginning of the 19th century to suppose that no influence of the State in the spheres of charity, education, or religion could be otherwise than mischievous. Hence the popular faith in Voluntaryism. Hence, too, the resistance on the part of the Nonconformists during a part of the Victorian reign to the establishment of any system by which the Government proposed to aid and inspect primary schools. Nevertheless time has wrought a remarkable change in public opinion on this subject. Matthew Arnold, who devoted much time and thought to inquiries into the systems of foreign countries, tried in his reports to convince his countrymen that if once an enlightened democracy were animated by a progressive spirit and noble ideals, it would be the part of wisdom to invoke the collective power of the State to give effect to those ideals. Great Britain as a nation has not yet accepted this dictum in all its fulness. But it is not difficult to account for the slowness and hesitation with which English statesmen have approached this subject, and for the lack of symmetry and of scientific completeness in so much of the national system of education as already exists. What there is in that system, both of merit and of defect, will be better understood by a brief reference to three or four of the leading countries of Europe, in which the people, less hampered than in England by the traditions of the past, have felt free to recognize earlier their national obligations in this respect, and to make more systematic provision for the education of the people.

***France.***

In France, Turgot in 1775 drew the outlines of an elaborate system of national education. Talleyrand, even in the midst of the political and social storms of 1793, formulated proposals for the establishment, by authority, of a school for every 1500 inhabitants. The decrees of Napoleon made further provision for academic and higher instruction, for the establishment of a State University, and for the certification of qualified teachers. The whole of the legislation of the Consulate and the First Empire contemplated a system essentially laic, military, and highly organized, under the direct control of the Government. From that time, notwithstanding frequent aberration of opinion and political change, increasing and generous sacrifices have been made by the French people to complete their edifice of primary, secondary, and superior instruction. Ecclesiastical influence became more pronounced under the Restoration, and in 1816 public subventions were made for the maintenance of schools. Under the reign of Louis Philippe, Guizot, with the advice of Remusat and Cousin, made special efforts to secure the co-operation of the Churches in the business of national education. In a circular addressed to 300 elementary teachers in 1833, they are exhorted to bear in mind that "education has never really flourished when the religious sentiment has not been combined, in those who propagated it, with the taste for enlightenment and instruction." Accordingly, the law of 1833 expressly enacted that the wishes of the parent should always be consulted and followed in what concerned religious teaching. This was effected partly by multiplying schools of different confessions and types, forbidding proselytism, and exempting children in mixed schools from teaching which their parents disapproved. The Government said in effect to their Churches: "The State cannot make itself denominational, but we invite the denominations to make themselves more national." The response to this appeal was not very cordial; and when in 1860 Matthew Arnold made his report on *Popular Education in France*, he foresaw that the compromise was not likely to last. The efforts of Catholics were so far successful that in 1878 official statistics showed that more than a fourth of the primary public schools for boys and nearly two-thirds of those for girls were under "religious" masters and mistresses. But these efforts, in turn, to obtain increasing control over the State schools generated corresponding intolerance on the part of the extreme secularists, such as M. Paul Bert; and in 1877 a law was passed excluding the bishops from the Supreme Council of Education. Further measures in 1880 forbade the Jesuits to take any part in teaching, either in public or in private schools; and in 1886 it was enacted that none but lay teachers should be recognized in the public schools. The various stages by which the popular education of France has been gradually and completely secularized are clearly and fully described by Mr Lecky in chapter vi. of his *Democracy and Liberty*. Notwithstanding the liberal subsidies, both national and departmental, by which the common school system is now supported, it cannot be said that the system is coextensive with the needs of the nation, or that it satisfies the wishes of the people. In a parliamentary paper prepared by the writer of this article it was shown (*Memorandum on the Working of the Free School System in America, France, and Belgium*, 1891) that the complete secularization of the public school had aroused the hostility of the Roman Church, and had caused a large number of schools and scholars to be detached from the public school system and taught independently in voluntary or confessional schools. The statistics of that year showed that of the 5,545,000 scholars reported as enrolled in primary schools, 1,166,477, or more than one-fifth, were in private or denominational schools; of these, 370,772 were boys and 795,705 were girls. In Paris the disproportion was still greater, for while 111,112 scholars of the age from 6 to 13 were in the public schools, 71,850, or nearly two-fifths of the whole, were in schools outside the State system.

The returns for 1899 show how this tendency has continued, and that the number of the *écoles confessionelles* as compared with those aided and regulated by the State continues to increase. There were in that year in public primary schools 95,233 lay teachers and 9929 *congréganistes*, and in private schools 6994 lay teachers and 38,757 *congréganistes*. The total number of scholars in private or confessional schools had risen to 1,324,684. Besides these numbers in primary schools proper, the returns show that in *écoles primaires supérieures* or in *cours complémentaires* there were enrolled 56,051 scholars, and in the *écoles maternelles* or infant schools 532,077 younger children.

The most notable of recent changes in France concerns the higher academic education. At the time of the Revolution there were twenty-one universities governed by local academic bodies independent of each other, and for the most part feeble and inefficient. Napoleon created in their stead one Imperial institution, which was intended, under the name of the University of France, to co-ordinate and control the whole educational organization in the country, under the direction of the Minister of Public Instruction for the time being, who was to be *ex officio* Grand Master of the University of France and Rector of the Academy of Paris. The local academies had no power to confer University distinctions; but degrees in Letters and in Science were instituted by the State, and demanded by it as a guarantee for admission to certain professions and public offices. The University of France, thus constituted, continued all through the Restoration, the Government of July, the Second Empire, and part of the third Republic to dominate the education of the country, notwithstanding the efforts of Guizot and others to substitute for the separate faculties and schools a number of independent universities, and to make them centres of intellectual life. The general desire on the part of scholars and men of science for decentralization, and for restoring independence and some power of initiation to the local academies, found expression in the Act of 1896 and in the Decree of July 1897, which practically abolished the State University of France, and gave to sixteen institutions, at Paris, Bordeaux, Lille, Lyons, Montpellier, Nancy, Toulouse, Aix, Marseilles, Caen, Dijon, Grenoble, Poitiers, Rennes, Besançon, and Clermont, each comprising several faculties, larger liberty and autonomy—*e.g.*, the power to grant diplomas and certificates apart from the State degrees. The new law also handed over to these universities such fees for enrolment, and for the use of laboratories and other facilities for practical work, as were paid by the students of the faculties. The history and probable educational effect of this great reform are admirably summarized by M. Louis Liard in his article *Les Universités Françaises* in the fourth volume of Special Reports on Educational Subjects issued (1900) by the English Board of Education.

***Belgium.***

It is interesting to compare with these details the history of the neighbouring country of Belgium, which during the same period has gone through similar educational experiences, but has arrived at different practical conclusions. Though small, it is a highly prosperous country, full of industrial enterprise and activity, and it presents in a compact form illustrations of some of the more important problems concerning

education, especially those which affect the relation of the State to religion and the Church. Its history dates from 1831, when, on its separation from the kingdom of the Netherlands, it received its constitution under King Leopold. At that date its population was 2,800,773. In 1897 the numbers had reached 6,586,593. The rate of annual increase in the population is 14 per thousand, as compared with Germany, 11; Holland, 13; Austria, 9; Great Britain, 8; Switzerland, 7; Hungary and Sweden, 10; Italy and Spain, 4; and France, ·09. The density of its population is remarkable, there being 224 inhabitants *par kilomètre carré*, as compared with Great Britain, 126; Germany, 96; France, 71; Italy, 109; Spain, 36; Sweden, 11; and Norway, 6. (See article BELGIUM.)

One of the articles of the Constitution of 1831 asserts definitely the principle of the liberty of instruction. Private or individual enterprise and initiative are therefore not forbidden; but owing to the completeness of the State provision for primary, secondary, academic, and technical instruction, there is little room for such enterprise, and, except on the part of clerical authorities desirous to secure provision for religious instruction, hardly any private schools can be said to exist. But this exception is important. Its history has shown in Belgium since 1831 successive changes in popular opinion on the relations between Church and State which have from time to time profoundly modified the educational system. At first the law, as it was consolidated in 1842, required every commune to maintain a school or schools for primary instruction, that is to say, for children of ages from 6 to 14. The cost of building was to be defrayed by the commune, and the annual maintenance was to be provided partly by a subvention from the State, in addition to a nearly equal sum from the commune, partly and to a much smaller extent —about 3 per cent. of the total revenue—from the fees paid by parents. Practically primary education was gratuitous in all the large towns and in many rural districts; and provision was made that in all cases the children of indigent parents could claim, either from the local charity *bureau* or from the commune, the means of exemption from the payment of fees. "The law of 1842 made religious instruction obligatory, and placed it under the direction of the minister of the faith professed by the majority of the pupils in the school, children not belonging to the denomination of that majority being dispensed from attendance at the religious lessons. Supervision of this religious teaching, including inspection of its methods and results and the choice of text-books, was entrusted to the ecclesiastical authorities, who were represented (in a consultative capacity) in the Central Office, and were required to make an annual report to the Minister" (see "Recent Legislation in Belgium," vol. i. of *Special Reports on Educational Subjects*, 1897). This compromise lasted thirty-seven years; but meanwhile there was a steady growth of one section of public opinion hostile to any "association of the State with the action of a favoured Church," on the ground that it violated the spirit of the Belgian Constitution. The law of 1879 accordingly prescribed that religious education should be left wholly to the care of the families and to the clergy of different faiths. The system of religious inspection was abolished, religious instruction ceased to be included in the curriculum of the communal schools, and in its place instructors were enjoined "to give moral precepts and to inculcate sentiments of duty, of love for country, respect for national institutions, and attachment to constitutional liberty." This provision was not found to satisfy the educational requirements of a nation in which the Roman Catholic Church exercises an exceptionally powerful influence. The purely secular, or rather non-religious, character of the State schools was from the first distasteful to the authorities of that Church; parents were exhorted to withdraw their children from the communal schools, and private and denominational schools were established by the efforts of the congregations and the clergy. These schools received no subventions from the State, yet they attracted year by year a larger number of scholars. In 1883 there were in the public or communal schools 320,709, and in the private or Catholic schools 479,280 scholars. It was computed that in that year there were for every 100 inhabitants in the kingdom 14 children in elementary schools, of whom 8·47, or 59·9 per cent., were taught in *écoles confessionelles*, and only 5·67, or 40 per cent., in the schools provided by the State. A strong Catholic majority at the general election of 1884 led to the enactment of a new law, which, though not relieving the communes from the responsibility of providing schools, gave liberty to place religious and moral instruction at the head of the curriculum, and also to accept as *écoles adoptées*, and to assist by public funds and recognition, the confessional schools which had since 1879 been maintained by the private efforts of the Church. Provision was further made entitling any twenty parents of children of school age to demand either a school of the normal communal type, or one which gave separate religious instruction in the tenets of the Church. Subsequent legislation in 1895 took a further step in the same direction, gave additional subsidies to private or confessional schools, and made religious instruction obligatory in the first or last half-hour of each school attendance, children whose parents so desired being excused. It further required that the inspection of religious instruction shall be exercised by the ecclesiastical authorities. The effect of this change has been to cause a large diminution in the number of communal schools and a considerable increase in the influence of the clergy. There is no immediate prospect of any reversal of the policy which has thus made the Belgian system of public education essentially denominational, although the proportion of Catholics has somewhat declined. The general election of 1900 resulted in the return of 85 Catholics, 33 Liberals, and 34 Socialists to the Representative Chamber, and of 47 Catholics and 29 Liberals to the Senate or Upper House.

The returns for 1899 show that a total of 940,370 children, or nearly one-sixth of the population, are in attendance in primary schools. Of these, 475,487 (292,382 boys and 183,105 girls) are in communal schools, 168,397 (57,310 boys and 111,087 girls) in adopted schools, and 120,416 (46,513 boys and 73,903 girls) in private or confessional schools, besides 176,070 infants in *écoles gardiennes*. It will be observed that the proportion of girls under direct clerical influence is greater than that of boys. In the staff of teachers the effect of the new law has been very marked. There were in 1894 in the communal schools 9275 lay schoolmasters and 200 members of religious orders, and in the denominational schools now "adopted" 1252 lay schoolmasters and 411 *religieuses*. Out of the 7418 mistresses, 3419 (of whom 3225 are employed in adopted schools) are *religieuses*. There are in the whole country 19 training colleges for men and 34 for women, and the aggregate number of normal students is 3585, who furnish an annual supply of certificated teachers (*diplomés*) of 915. The total annual cost of primary education is 33,318,328 frs., of which the State contributes 13,868,045 frs.; the communes, 15,402,204 frs.; the fees of parents, 1,314,410; charitable endowments, 226,801; and the *bureaux de bienfaisance*, 334,372.

Some light is thrown on the degree of efficiency attained in primary education by the official returns of the examination of young men drawn annually for military service. These show that the number unable to read and write was in 1870, 29·23 per cent.; in 1880, 21·66 per cent.; in 1890, 15·92 per cent.; and in 1898, 12·83 per cent. In 2116 continuation schools, held for the most part in the evening and for adults, there were 91,269 scholars. The provision for secondary instruction may be regarded as ample. In the special normal schools for higher or intermediate teachers there were in 1898, 56 men and 92 women students. The High Schools or *Athénées Royales* were attended in 1897 by 5657 scholars, the State intermediate schools (*écoles moyennes*) by 13,923 boys and 5497 girls, and the communal secondary schools by 1518 boys and 1440 girls. Academic education (*enseignement supérieur*) in connexion with the four Universities of Brussels, Ghent, Liège, and Louvain is provided for a total number of 4951 students, or 75 for every 100,000 of the entire population. Of these, 536 are entered in the Faculty of Arts and Letters, 1028 in that of Science, 921 in Law, 1172 in Medicine, and 54 in Theology. For special instruction in the Fine Arts there are in the kingdom 87 academies and schools of design with 15,958 pupils, and 53 *conservatoires* or *écoles de musique* with 13,063 pupils. Thus the country may be said to possess, in proportion to its population, a very complete equipment of primary, secondary, technical, and academic or university education.

**Holland.**

A Dutch law of 1857 established throughout the Netherlands an excellent system of national education. Secular teaching alone was to be endowed with public funds. No schoolmaster in the national schools was allowed to give religious instruction, or "to say, do, or tolerate anything disrespectful to the religion of any class of pupils." Religious teaching was left wholly to the care of religious bodies, who were permitted to provide it in the schoolrooms, outside the regular school hours. This system was confirmed by the law of 1878. But it proved unsatisfying to the large and earnest minority of religious persons who had set up at their own expense schools for the denominational education of their children. In 1888 no fewer than 480 of these "Bible schools" were found to be maintained by voluntary gifts, with 11,000 teachers and 79,000 pupils (cf. Lecky, *Democracy and Liberty*, ii. p. 72). The law has since 1889 been so altered as to permit these schools, on fulfilling certain conditions of efficiency, to receive regular subsidies and inspection from the State. The result is in Holland a mixed system which, while leaving the public secular schools undisturbed, recognizes voluntary and religious schools, and offers to aid them with grants of public money.

The following statistics show the latest returns respecting primary education in Holland. Further details will be found in the important report of Mr. Balfour in the fourth volume of Special Reports issued by the English Board of Education.

In the school year 1898–99, 730,688 pupils were receiving primary education in Holland. This figure includes both girls and boys. The total population on 31st December 1898 was, according to the communal population returns, 5,074,632.

The 730,688 pupils were distributed among the various classes of schools as follows:—

| | | |
|---|---|---|
| *In Public Primary Schools—* | | |
| Boys . . . . . | 280,152 | |
| Girls . . . . . | 223,579 | |
| | | 503,731 |
| *In Subsidized Private Primary Schools—* | | |
| Boys . . . . . | 130 | |
| Girls . . . . . | 770 | |
| | | 900 |
| *In Private Primary Schools not receiving Government subsidies—* | | |
| Boys . . . . . | 99,340 | |
| Girls . . . . . | 126,717 | |
| | | 226,057 |
| Total, . . . | | 730,688 |

It is noticeable that whereas the figures for all primary schools amount for the year 1899 to 730,688, and for the year 1898 to 719,415, showing an increase for the attendance of all schools of 11,273, the increase has been mainly confined to the public schools and the unassisted private schools.

Possibly the explanation of these facts may be found in the conditions attaching to Government grants to private or denominational schools.

Such grants were first instituted by the law of 1889, which established the compromise by which the long-standing religious difficulty seems finally to have been settled. Yet after ten years of operation, the law of 1889 has enabled the Government to make grants to eighteen only out of 1448 private schools. And while the number of schools receiving Government grants has decreased, the unassisted private schools show a great increase, larger even than that of the public schools.

The following are some of the conditions that have to be fulfilled by a private school claiming a Government grant under the Act of 1889:—

1. It must be managed by an association or institution possessing the rights called "civil personality" (similar to the English "rights of a corporation").
2. Its headmaster must possess the rank of *instituteur-en-chef*, or "master-in-charge."
3. The instruction must comprise all the obligatory subjects of primary education.
4. Instruction must be given in obligatory subjects during at least eighteen hours per week.
5. The school must possess a body of rules and regulations which are binding upon it, and must annually receive the signature of the Inspector of the arrondissement, whose duty is to see that the rules are not contrary to school law.

It is, therefore, to the conditions which preclude private schools from applying for Government grants that we should look for an explanation of the figures already given. These negative conditions are as follows:—

No school can claim a Government grant
(1) in which there are not more than 25 pupils more than six years of age;
(2) in which the school fees exacted reach an average of 80 florins per pupil;
(3) which has been established or is managed for pecuniary profit.

It should further be noted that whereas Government grants are made to public schools, in aid of new buildings, repairs, &c., to the amount of 25 per cent., no such grants are made to any private school.

If the explanation of the small number of private schools receiving Government grants is not to be found in the conditions attached to them by the law of 1889,—and it will be generally agreed that those conditions are in no sense onerous,—then the only explanation is that the members of religious and charitable associations who direct the private schools of the country prefer partial freedom from Government control, and will not sacrifice this in order to gain Government assistance.

**Germany.**

In Matthew Arnold's report to the Schools Inquiry Commission in 1866, he said, "The school system of Germany, in its completeness and carefulness, is such as to excite the foreigner's admiration." There is, in fact, no country in Europe in which more skill, statesmanship, and public spirit have been brought to bear on national education. So early as 1649 the General Synod of Würtemberg (G. Perry, *German Elementary Schools*, p. 24) required that parents should send their children to school. Similar regulations were enforced in Saxony in 1764, in Prussia in 1736, and in Bavaria in 1802. The Prussian Constitution of 1850 declares "that adequate provision for the education of the young is made by means of public schools; and that parents and their representatives may not leave their children and foster-children without the instruction prescribed for the public elementary schools." The laws in the several German states differ slightly in some details, but generally enforce attendance from the age of six to fourteen, and an additional attendance at a *Fortbildungschule* is frequently required in the evenings or on Sundays, *e.g.*, in Saxony, Saxe-Weimar, Saxe-Coburg-Gotha, and Hesse, for either two or three years after attaining that age. In the kingdom of Saxony alone there were 1900 such institutions, with 77,808 boys. Long habit and tradition and the public opinion of the industrial classes have rendered the attendance laws easy of enforcement, and it is computed that the absences from school vary from 3·6 to 7 per cent., and seldom exceed 6. Moderate school fees are exacted in Prussia, Saxony, and Bavaria; but some municipalities—notably those of Berlin and Dusseldorf—have made the instruction in the communal schools gratuitous. (Arnold, *Report to Education Department*, 1886, p. 4.) On the average of the whole kingdom of Prussia, school fees meet 20 per cent. of the cost of teaching in the popular schools, endowments 12 per cent., the municipalities 55 per cent., and the State 12 per cent. In Bavaria the fee is fixed at a minimum of eightpence and a maximum of one shilling and fourpence per quarter. In Saxony the minimum fee is three shillings per annum, but a higher charge is made according to the means and social status of the parents. But in all the states provision is made for the gratuitous instruction of the very poor. The general rule in Germany is "a school fee where the scholar can afford to pay it, remitted where he cannot." As to the quality of the school instruction, Arnold, in the same report, describes a fuller programme for the elementary schools than in England: religion, German, English, history, geography, arithmetic and algebra, geometry, writing, drawing, singing, and gymnastics being all included. In the opinion of that acute observer, the methods of teaching in Germany were more gradual, more natural, and more rational than the English; and the religious teaching, chiefly in the form of Bible history and extracts and evangelical hymns, appeared to him to be specially interesting and intelligent. In 1896 Prussia had a population of 31,840,795 persons. It was then computed that 223 out of every thousand of the population were between the ages of five and fifteen, and that the number of scholars actually in attendance in the Volkschulen was 5,236,826.

The famous Prussian Minister of Instruction, Dr Falk, sought energetically in his anti-clerical campaign (the *Kultur-Kampf*) to make national education more completely secular in its character. The drastic "Falk Laws" of 1873 were chiefly directed against the Catholic Church and the influence of the priests in education. They gave to the State the right to inspect all educational institutions, both private and public, and resulted in the closing of many seminaries and establishments of religious orders. But after the death of Pius IX. in 1878, diplomatic relations between the Government and the Vatican were restored, and Prince Bismarck succeeded, after direct negotiations with Rome, in mitigating the severity of the Anti-Catholic Laws. Subsequent efforts of the Catholic party in the Reichstag to increase clerical influence over education have, however, failed. But from 1887 a more conciliatory policy towards the religious bodies has been adopted in Prussia, and provision has been made in the State schools for the separate religious instruction of Roman Catholics, Protestants, and Jews in accordance with the wishes of the parents. Dr Falk resigned office in 1879, and died in 1900.

It is evident that Germany owes as much as any other country to a strong sense of the national importance of education, and to the consistent and resolute efforts of her statesmen during many years to develop and to perfect it. Hence, as Mr Sadler has said (*Problems in Prussia, Special Reports*, vol. iii. p. 89), "Through the labour of generations the public higher schools for boys stand, from several points of view and in many important respects, as models to the world. They are unrivalled in their high level of many-sided attainments. Thought has been lavished on the planning and concentration of their studies. The quality, the range, and the method of their teaching are under the watchful care of State inspectors, themselves experienced in the work of secondary education. All the schools are thus scrupulously kept up to an exacting standard of excellence. Prussia, in particular, owes much to Stein, to Humboldt, to Wolf, and to Schleiermacher, and in the department of primary education to the ideas of Pestalozzi and to the inspiration of Fichte." So early as 1794 the *Allgemeines Landrecht* formally declared schools and universities to be State institutions. In 1808 there was established a special section of the Home Office for worship and public instruction, and from the year 1817 this section has been separated from the Home Office and has constituted an independent Education Department.

**Switzerland.**

Switzerland, with its small population of 2,993,334, has long been distinguished for its educational efforts and resources. It was the home of De Fellenberg and of Pestalozzi; and it is here that some of the most fruitful experiments in public instruction have been tried. An article in the Federal Constitution requires that throughout the country "primary instruction shall be obligatory, and in public schools gratuitous."

All the cantons comply with this general law of the Constitution; but each of them has its own school law, and the right to provide and to regulate their local schools is jealously guarded by the several cantons. Every proposal to extend the power of the Bund over primary education has been met with strenuous opposition.

The total expenditure from public funds on all the grades of education amounts to £1,617,201; that is to say, £948,788 on primary education, £223,118 on higher primary and continuation schools, £30,530 on training colleges, £167,089 on lycées and other secondary and intermediate schools, £97,250 on universities, and £150,426 on technical instruction. The contribution of the communes amounts to 51·7 per cent. of the total expenditure, that of the cantons to 42·2 per cent., and that of the Bund to 6·1 per cent., this last being mainly a recent grant for technical instruction only, and appropriated chiefly to the *Polytechnicum*, or Technical University at Zurich, which is a federal and not a cantonal institution. The entire revenue for general education may thus be said to be derived from local resources. There are differences of some importance in the proportion of revenue assigned in different cantons to primary and secondary instruction respectively; *e.g.*, in Bern and Lucerne secondary and higher schools are gratuitous and the public subvention is large; in Zurich and other cantons moderate fees are charged.

By a decree of April 1891 the Swiss Confederation proposed to grant subsidies for the encouragement of technical and commercial instruction, and also to furnish bursaries for scholars specially qualified by their capacity and industry, to enable them to attend the higher courses of a local commercial school. These must be boys of fifteen, who are to undergo three years' instruction, and at the end to receive a diploma. There are fourteen such schools in Switzerland. The chief subjects of instruction are: mathematics, arithmetic (including book-keeping, office work, and commercial law), political economy, some branch of technology, natural science, chemistry and industrial geography, one foreign language at least, type-writing, shorthand, gymnastics and military exercises, visiting factories under supervision, and writing descriptive accounts of the same. Fees are paid amounting to from 30 to 100 frs. for natives and 60 to 200 frs. for foreigners. In 1895, in the school subsidized by the Federal Government, the fees paid by students amounted to 47,891 frs., and the Federal subsidy to 63,250 frs. The total number of pupils was 542.

The provision for the training of teachers is ample. There are 24 State and 13 private normal colleges, with 2600 students. Most of these institutions are training colleges pure and simple, but ten of them form parts or appendages of higher primary schools.

There are no pupil teachers, but candidates for admission to a training college must have been in a higher primary school for two years. The curriculum extends over two or three years. Prominent importance is given to music, to pedagogy, theoretical and practical, and every student is required to study one language other than the mother-tongue, and some branch of experimental science. Arrangements are also made for an annual Alpine excursion of three or four days for botanical or geological research, or for visits to famous institutions. The annual cost is about £22 for each student, the State and the communes contributing three-fourths; the rest is partly derived from voluntary contributions and partly from the fees paid by parents; but by means of bursaries, graduated to suit the private circumstances of the students, these fees are so reduced that they seldom amount to £6 per annum. Certificates of competency are granted by the Council of Education for each canton, and not by the Federal Government. There is only one (in Canton St Gall) training college for higher primary or for secondary schools, but candidates who have had the full qualification of an elementary teacher, and have in addition served one year as assistant teacher and studied for two years at a university, may come up for the higher teacher's certificate (*Sekundärschullehrer*). The teacher is not, as in England, required very early to pursue his professional and his general education *pari passu;* he must up to 17 at least continue in a course of liberal training, and not attempt to take up pedagogic study or practice until after that age. The religious difficulty appears to have been for the present satisfactorily solved. Matthew Arnold (*Special Report to the Education Department*, 1886) cites the article of the Swiss Constitution: "The public schools shall be capable of being attended by adherents of all confessions without injury to their freedom of faith and conscience." He adds that no difficulty has arisen in giving effect to this principle. The Swiss communes have in every popular school religious instruction in the faith of the majority—Catholic instruction in cantons like Lucerne, and Protestant in Protestant cantons like Zürich. Where there are enough children of the confession of the minority, a separate school is established for them; where there are not enough, the children often attend the religious instruction of the majority, if the parents consent. In the great town school of Lucerne, 400 Protestant children were found attending in class with 2900 Catholics, the Catholic children receiving their religious instruction in the school, and the Protestant children out of school and out of hours.

**Scotland.** The foregoing details as to four of the most progressive countries of Europe will serve as a basis of comparison, and will render more intelligible the fact that in Great Britain the educational problem has from the first presented special difficulties, and has been less systematically and more tardily solved. In the northern part of the island the solution of that problem has proved less complex than in England and Wales. Some of the conditions in Scotland have been exceptionally favourable. So early as 1560 the Church Assembly, largely owing to the influence of John Knox, put forth its *Book of Discipline*, containing provisions, soon afterwards ratified by the Estates of the realm, requiring that every parish kirk in a town should have its Latin school, and that in the rural districts there should be elementary schools, and in large towns colleges for teaching logic, rhetoric, and the Greek and Roman languages. This legislation, confirmed by Acts of the Scottish Parliament in 1633 and 1696, and further enforced in 1803 by requiring each parish to provide a house and stipend for a schoolmaster, has resulted in the gradual production not only of a higher level of education in the country, but also of a universal recognition of the value of instruction on the part of the community, including peasants and persons of all ranks. The parochial schools, the burgh schools or academies, have for many generations been in close relation to the Universities. The religious difficulty so acutely felt in the southern portion of the island has been greatly reduced in Scotland owing to the practical unanimity of the people in the adoption of the Presbyterian form of faith. Hence the educational progress of Scotland has in many respects been more steady than in England, and has not been confined to the primary schools. The report of the Scottish Education Department for 1899 shows that with an estimated population of 4,290,619, the country possesses 3535 separate departments in primary schools, with an attendance of 681,334 scholars, and 1016 evening continuation schools, with 57,729 scholars. The return of teachers shows that 10,676 are fully certificated, 2371 are assistants, and 4111 are pupil teachers. The experience of the Scottish Education Department, like that of the English, has led by degrees to the gradual abandonment of the practice of individual examination of children in standards as the basis for the computation of the parliamentary grant, and to the substitution of a normal or block grant for one determined by the number of passes in separate subjects. Otherwise the features of the Scottish system which distinguish it from that of England are: (1) the provision that "the normal grant may, on the recommendation of the inspector, be reduced by not less then one-tenth nor more than one-half for faults of instruction and discipline," thus retaining the principle that public aid shall be proportioned to the efficiency of the school (Art. 32); (2) the award of a merit certificate after the age of twelve to all who pass a satisfactory examination in the ordinary subjects of an elementary school course, thus recognizing the importance of an individual examination of scholars at the end of their course; (3) the special encouragement given to advanced departments in elementary schools; (4) the larger proportion (more than two to one) of trained to untrained teachers, and of head teachers who have graduated at the Universities; (5) the increasing influence of the Scottish Education Department over secondary and technical schools, exercised by means of inspection, by direct subsidies under the Education and

Local Taxation Account Act (Scotland) of 1892, and by the award of leaving certificates and bursaries after the examination of pupils.

In Ireland the problem of national education has assumed a shape differing in many ways from that prevailing in other parts of the United Kingdom. Its present system owes less to local initiative—either private or municipal—and more to the direct action of the Government. The population is more sharply divided in religious profession, at least 75 per cent. being Roman Catholics, about 11 per cent. members of the Anglican Church, and 11 per cent. Presbyterians, chiefly in the province of Ulster; the minor dissenting communities, so numerous in England, being almost unknown. These conditions should be borne in mind in any attempt to estimate the historical development of the Irish system or to compare it with that of Great Britain. In 1831, two years after the enactment of Catholic emancipation, Lord Grey's Government established a Board of Education composed partly of Roman Catholic and partly of Protestant members. To this body was entrusted the control of all funds which might be annually voted by Parliament for the purpose of erecting schools, visiting and inspecting them, making gratuities to teachers, establishing a model school for the training of teachers, and supplying school-books and necessaries. Before this date grants had been made in aid of the Charter Schools, the Foundling Hospital, and the Kildare Place Society—a body which had been founded in 1811, and had sought to provide a system of schools wherein Catholics and Protestants might be instructed together, and the Bible might be read without note or comment. This society did not wholly succeed in obtaining the co-operation of the heads of either the Catholic or the Established Church. The Commissioners, however, in the earlier stages of their administration endeavoured to obtain such co-operation by means of a system of combined moral and literary instruction, and separate religious instruction for children of different faiths. At first the Board also prepared for general use books of Scripture extracts from the historical portions of the Bible and from the Psalms, the Gospel of St Luke and the Acts of the Apostles; and for a time the use of such books continued in the schools with the partial approval of the authorities of both Churches. But this compromise ultimately failed. The story of its failure, and of the gradual steps by which the Commissioners have abandoned the attempt to secure a mixed and comprehensive plan and have adopted a practically denominational system, is fully told by Mr Sadler (*Special Reports*, 1896–97, p. 211), and is further described in careful detail in a memorandum in the same volume by Mr C. T. Redington, late Resident Commissioner. It must suffice here to refer to the most recent changes, especially to those which have resulted from the Report of the Viceregal Commission of Inquiry into Manual and Practical Instruction, 1897. With regard to the administration of the public grant, there is a fundamental difference between the conditions under which the Irish Commission acts and those which have controlled the English Education Department. This Department does not appoint teachers nor dismiss them, promote them or pay them. It neither builds nor furnishes the schools, nor regulates the duties of the staff, the choice of books, or the course of instruction. It simply makes a grant in aid to local managers, who have full power to supply these things at their discretion. Hence there was no other way open to the central Department to secure the efficiency of a school than by withholding a grant, or graduating it in accordance with the result of examination. But in Ireland the Central Board generally erects the school buildings of the "vested schools," it has the power to fix the stipends of teachers, to augment those stipends for good service, and to make all needful provision for the equipment of the school and for determining the course of instruction. Thus the Board has ample means of securing a good educational equivalent for its outlay. Nevertheless, until recently a considerable portion of the grant paid to teachers was made to depend on the answers given by the scholars when examined individually in each separate subject of a very extensive programme. The Commissioners have lately recommended a considerable modification in the system of distributing the grant. New rules were sanctioned in 1900 providing that teachers should in future be paid (*a*) a fixed salary, called a *grade* salary, there being three grades of teachers; (*b*) an additional salary called *continued good service* salary, which may be increased triennially; and (*c*) a capitation grant on the average attendance of the scholars. The teacher's position in the school, his length of service, and the goodness of his teaching, as attested by the proficiency of the scholars and the reports of the inspectors, are all taken into account in determining the salary of the teachers and their promotion from one grade to a higher. In this way the administration of the funds is calculated to secure efficiency by other means than that of payment by the results of individual examination, a plan now definitely abandoned. Other provisions in the newest regulations of the Board, for increasing the responsibility of local managers, for the preparation of reports of progress, and for giving to parents a more direct interest in the educational welfare of their children, have been very carefully framed in the light of recent experience, and are full of promise for the future.

**Ireland.**

A new department has been created for the promotion of technical instruction, and an active society, for Irish Agricultural Organization, is already trying some valuable and most hopeful experiments in the establishment in the rural districts of creameries, fruit-growing, poultry-yards, and the economy and distribution of farm produce.

The estimated population of Ireland being 4,531,051, the returns show that the number of pupils on the rolls of the national schools was 796,163, or more than one-sixth of the population. The number in average daily attendance, however, was 513,852, or only 64·5 per cent. as compared with the number on the rolls. Of the scholars in (*a*) schools under Roman Catholic teachers exclusively, 192,278, or 94·7 per cent., are Catholics, and 11,103 are Protestants; in (*b*) schools under Protestant teachers exclusively, 7512, or 9·8 per cent., are Catholics, and 69,240, or 90·2 per cent., are Protestants; and in (*c*) schools under Catholic and Protestant teachers conjointly, 3818, or 58·8 per cent., are Catholics, and 2672, or 41·2 per cent., are Protestants. The proportion of schools which are specially denominational schools, and are solely attended by Roman Catholic or by Protestant scholars, has steadily though slowly increased, and the last returns show that it reaches 62·5 per cent. The total revenue of the schools is £1,215,816, of which £1,149,692 is derived from the State, including £83,818 from the Customs and Excise grant. From all local sources together, including subscriptions and endowments and the fees paid by parents, the amount available is only £66,124. It is computed that the sum needed per head for elementary education is £2, 7s. 11½d., of which £2, 5s. 3d. is contributed by the State and 2s. 7½d. from all other sources.

The Board of Education maintains one Training College (undenominational), in Marlborough Street, Dublin, under its own management, and subsidizes four other Training Colleges, of which two for men and one for women are under the care of the Catholic hierarchy, and one for men and women is managed by the Protestant Episcopal

Church of Ireland. These institutions provide training for 380 students in the two years' course, and for 217 in the course for one year. The total number of students who passed the final examination qualifying them for recognition as teachers was in 1899, 159 men and 159 women.

The Board does not provide or support secondary schools, but encouragement is furnished by the examinations and certificates, with result fees, under the Irish Intermediate Education Act of 1878. All schools, whether denominational or not, including those of the Christian Brothers, are admitted to participate in the distribution; and in 1890 the sum allocated under the Local Taxation Act made it possible to augment the result fees, and was placed at the disposal of the Intermediate Education Board for that purpose.

***England and Wales.***

In England the problem of national education has been rendered more difficult, partly by the complete absence until 1846 of any national recognition of the necessity of public education, partly from the great variety of Churches and of theological beliefs in the nation, and partly from the practical isolation of the Universities, the intermediate schools, and the public elementary schools from one another. Of these difficulties, one which has given most concern and trouble to English statesmen has doubtless been that of determining the religious basis of national education. As one studies the history of thought and controversy in other countries in regard to religious teaching, it is seen that there are possible three sharply-defined forms of opinion on this subject:—(1) There are those who contend that the State being a secular institution, having no religious creed of its own, and yet composed of persons of very different religious belief, ought to confine itself absolutely to secular instruction, and to leave the teaching of theology to the several Churches. This is the principle on which the school systems of France and of the States of the American Union are founded. (2) There are others who contend that education is wholly incomplete without religion, that the teaching of religion means the enforcement of a creed, that the proper exponents of a creed are the authorized ministers of religion, and hence that a system of national education should be essentially denominational, and that if the State helps or controls primary education at all, it should do so through the agency of the Churches and their ministers. Throughout all Europe the Roman Catholic Church has always insisted on this view, and has been unwilling to entertain any proposals for a compromise. In some sections of the English Church the same belief exists, although to a much smaller extent. (3) There is another and a large class of the friends of education who dread the exclusion of the Bible and religious teaching from the common schools, but who do not desire to make such schools the propaganda for any particular sect. They regard the reading of the Bible, with simple undogmatic explanation, as appropriate to the intellectual needs of childhood, and well suited for general adoption by Christian parents, so long as full liberty is given to the minority to withdraw their children from any religious instruction which they may disapprove. This is the principle which was adopted by the supporters of Joseph Lancaster, and by the British and Foreign School Society in 1811, and recognized in the Education Act of Mr Forster in 1870. Clause 14 of that Act, generally known as the Cowper-Temple Clause, enacts that "in any school provided by a School Board, no religious catechism, or religious formulary which is distinctive of any particular denomination, shall be taught." The School Boards are not bound to include religion in their course of instruction. But in 83 per cent. of the School Boards of England, including that of London, it is the custom to give careful scriptural teaching, to make the children familiar with Bible history, with the life and teaching of the Founder of Christianity, with the poetry and literature of the Old Testament, and with such devotional or ethical parts of the Bible as are suited to the comprehension of children, it being understood that controversial teaching on points on which the several Churches differ shall be wholly excluded. This comprehensive and scriptural but unsectarian ideal has proved very acceptable to English people, and especially to parents. At this moment it prevails over a considerable and increasing majority of the schools aided and inspected by the State.

There is, however, nothing inconsistent between the views of those who hold this third opinion and the recognition of the denominational principle within certain limits. Accordingly, the Act of 1870 leaves full liberty to the schools attached to the several Churches to give to their scholars the distinctive dogmatic teaching to which the managers attach special importance, provided that the secular instruction shall fill four-fifths of the day's exercises, and shall be thoroughly efficient. On these conditions, which are verified and certified after examination by H.M. Inspectors, the State recognizes voluntary schools and makes liberal grants for their maintenance. And in consequence there is not a single religious body in England or Scotland which does not, in so far as it is concerned with elementary education, comply with the regulations of the State and receive aid from it; nor is there a remote corner in either country where the inhabitants are not within reach of a public elementary school under Government inspection.

The particulars given in vol. vii. p. 679 of the *Encyclopædia Britannica* (ninth edition) bring up the story of administrative changes to the date of 1877, and show what was the constitution of the newly-formed School Boards and what were their powers. Mr Forster had hesitated to make school attendance compulsory by the Act of 1870, but in Clause 36 of that Act he plainly contemplated such an early change in public opinion as would justify local bodies in enforcing attendance. Hence a later Act in 1876 enforced the duty of every parent to send his child to school between the ages of 5 and 14, forbade employment under that age except to those who procured a labour certificate, and provided that indigent parents might claim from the guardians the payment of school fees. The same Act provided that the grant payable to a school should not exceed the limit either (*a*) of 17s. 6d. per scholar in average attendance, or (*b*) the total income derived from other sources than the grant. These limitations have since disappeared. In 1880 Mr Mundella's Act established direct and universal compulsion, and empowered the local school authorities to enforce it. In 1891 Sir W. Hart Dyke's Act practically abolished the payment of school fees, and thus threw upon the State the duty of compensating school managers for the loss of nearly two millions of annual revenue hitherto contributed by parents. A subsequent Act in 1896, introduced by the Vice-President, Sir John Gorst, provided a Special Aid Grant for the further relief of voluntary school managers. In the year 1890, before these great changes were made, the Government grants to elementary schools amounted to £3,326,177, the voluntary subscriptions to £758,670, the local rates levied by School Boards to £1,320,487, and the contributions of parents in the form of fees to £1,940,546. Later legislation during the administration of Lord Salisbury had the effect of altering materially the proportions in which the educational revenue is provided.

The whole of that revenue for the year 1899–1900

amounted to £12,336,986. This sum was made up as follows:—

| | |
|---|---|
| Endowment | £156,012 |
| School Board rates | 2,959,717 |
| Voluntary contributions | 812,104 |
| Fees and payment for books | 262,135 |
| County Council grants for technical instruction | 35,930 |
| Other local sources | 108,107 |
| Government grants, viz:— | |
| Annual grants | 4,993,115 |
| Fee grant under the Act of 1891 | 2,327,416 |
| Special aid grant to voluntary schools under Act of 1896 | 669,772 |
| Science and Art Department | 12,678 |
| | £12,336,986 |

Thus it is seen that the contributions from public sources, including the grants from the Treasury and from local taxation, amounted to £11,106,735, out of a total expenditure of £12,336,986. In the near future the contributions of parents and of voluntary subscribers may reasonably be expected to bear a yet smaller proportion to the total expenditure, and public control will in corresponding measure supersede private management.

These financial changes have not been without an important influence on the character of elementary education. It should be remembered that the Department does not appoint or dismiss the teachers, nor pay them, nor recognize them as civil servants. The curriculum of instruction is largely in the hands of the local managers, and from the first the main influence of the Education Department has been exercised through its methods of awarding grants to these bodies. In fact, during many years the prime function of the Department was not to direct education or to set up a national system, but to distribute a grant in aid of local effort, and to do this on a graduated system under such conditions as would stimulate improvement and ensure to the nation a good educational return for its expenditure. In this respect the English system has materially differed from more imperative forms of educational administration adopted in other countries. A Royal Commission of 1853, presided over by the Duke of Newcastle, recommended the adoption of the principle of payment by results in the crudest and most uncompromising form, and Mr Lowe's Code of 1860 was designed to give effect to that recommendation. He said in effect: "We do not insist on the adoption of any educational system, but we say if the Voluntary managers will show us certain results we will help them with a grant. Thus if our conditions are not fulfilled, the nation will find the plan economical. If the plan proves not to be economical, it will be very efficient, for the instruction will be worth paying for." Thus originated the system commonly known as payment by results. The grants were to be proportioned to the efficiency of the school, as determined by the individual examination of the scholars in reading, writing, and arithmetic alone. Later experience has by slow degrees materially modified the application of this principle, and has, indeed, partly discredited the principle itself. The plan of measuring the efficiency of the school solely by the number of scholars who were able to pass the examination led to the adoption by teachers, in many cases, of merely mechanical methods, designed rather to secure the maximum number of passes than to cultivate the intelligence of the scholars or to subserve the higher purposes of school discipline and training. Mr Forster, in 1870, was one of the first to see the inadequacy of the system, and in the Code of that year he added grants for history, grammar, science, and other humanizing subjects. Subsequently special grants were made for discipline and organization; and in 1881 Mr Mundella sought to enlarge the curriculum by permitting a wider option of additional scientific subjects and otherwise, by encouraging for the first time the Frobelian system of training and manual exercise in the infant classes; and by the introduction of a supplementary "Merit Grant," carefully graduated and designed to recognize and reward any form of excellence in discipline or organization or general intelligence which was not capable of measurement by the results of individual examination as tabulated in a schedule of "passes." A second Royal Commission of 1887, presided over by Lord Cross, was instituted to inquire into the operation of the Elementary Education Acts, and in its final report declared its opinion

> "That the distribution of the Parliamentary grant cannot be wholly freed from its present dependence on the results of examination without the risk of incurring graver evils than those which it is sought to cure. Nor can we believe that Parliament will continue to make so large an annual grant as that which now appears in the Education Estimates without in some way satisfying itself that the quality of the education given justifies the expenditure. Nevertheless we are unanimously of opinion that the present system of payment by results is carried too far and is too rigidly applied, and that it ought to be modified and relaxed in the interests equally of the scholars, of the teachers, and of education itself."

Accordingly, the Commissioners proceeded to recommend some modifications of the plan by which the amount of the grant payable to schools was at that time awarded; *e.g.*, that there should be a fixed grant of 10s. per scholar, and a variable grant of not less than the same amount, dependent partly on the results of individual examination and partly on various conditions hitherto recognizable for the purpose under the name of the "Merit Grant," the principle of which they sought to retain, though under a slightly altered form. These were moral training, order, obedience, general intelligence, and right classification. The Commission added, however, that in distributing the variable grant special stress should be laid upon proficiency in elementary subjects. These recommendations were substantially enforced by subsequent changes made during the Vice-Presidencies of Sir W. Hart Dyke and Mr Arthur Acland. Later experience, however, has led the Education Department to abandon altogether the attempt to graduate the grant according to the degrees of efficiency in the schools. In place of testing the proficiency of individual scholars, there is to be one summary estimate of the work of the school; in place of an annual examination, occasional inspection without notice; in place of a variable grant dependent on a report in detail on the several subjects of instruction and on particular educational merits and defects, one block grant payable to all schools alike. This grant is fixed at either 17s. or 16s. per head in infant schools or classes, and at either 22s. or 21s. for older children; the gain or loss of one shilling being the only difference recognized between the best schools and those which are not so bad as to justify the withholding of the grant altogether. It is hardly to be expected that this arrangement will be regarded as the final solution of the problem. It may possibly have the effect of reproducing the state of things which provoked the censure of the Duke of Newcastle's Commission of 1853, and which led to the novel and somewhat drastic expedient of determining the amount of the grant solely on the results of individual examination of scholars. Various expedients have been suggested for neutralizing the effect of so large a relaxation of the conditions by which it has been hitherto sought to secure accuracy and thoroughness in teaching. Among these, two have already been referred to as having been adopted in

the Scottish Code: a provision enabling an inspector to recommend deductions for specified faults in instruction, and a provision for the award of a merit certificate, to be given to a scholar as the result of an individual examination at the end of his or her school course; this latter plan of a leaving certificate having been in practical working, with very satisfactory results, in France for many years. Neither of these expedients has yet been adopted by the Board of Education for England and Wales, but by this or by some other means it will probably be found necessary to make greater provision than the newest Code furnishes for stimulating apathetic school managers and teachers to make efforts for improvement, and for assuring Parliament that its large annual grants are wisely, economically, and fruitfully expended.

The character of the instruction in the public elementary schools has in other ways been materially affected by the system on which the central Department has awarded money payments. Successive Codes and Acts of Parliament have recognized the age of fourteen as the limit of primary instruction; and after that age, and the completion of the curriculum known as the "seventh standard," the ordinary grant to elementary schools ceased to be payable in the case of any scholar. But increasing numbers of scholars have shown a readiness to remain and pursue an advanced course of instruction, without going on to schools of the higher or secondary rank. The Science and Art Department has been for many years administering special grants for drawing, design, and various branches of science; and these grants have been still available for scholars who had completed the elementary school course. Hence School Boards and Voluntary managers who have desired to retain scholars after the age of 14 have been led by financial considerations to give special prominence to those subjects for which grants were claimable from the Science and Art Department. But this has proved to be a partial and very inadequate provision, since the developed programme of what are called "higher grade schools" is often needed in the literary and general as well as in the specific and technical direction. A demand has arisen for schools or upper departments analogous to the *écoles primaires supérieures* which have proved so successful in France. This want is being recognized by the Government. By the Act of 1900 the Science and Art Department ceases to have a separate existence and to make separate payments for special branches of science. The new Board of Education, by which title the whilom Education Department is now known, is charged with the general supervision of primary and secondary, including technical and scientific, instruction, and will doubtless bring the various educational agencies into due relation to each other and make them take their places as parts of one coherent system. In such a system a place must certainly be found for "higher grade schools" such as have proved highly popular, especially in the great industrial cities of the North. They are not secondary schools, but merely places for continuing the instruction for an additional two or three years on the general lines followed in good elementary schools. The precise relations which are to subsist between these institutions and others, and indeed the true delimitation of the respective provinces of primary and secondary instruction, are matters which have been the subject of judicial decision and much debate. But they remain at present unsettled, and await the decision of Parliament and the new Board. One result of the existence of higher grade schools occupying, as they do, a kind of borderland between primary and secondary instruction, will probably be that the future local authorities will no longer be School Boards charged with the interests of elementary instruction only, nor new bodies concerning themselves with secondary instruction only, but single local authorities having cognizance of all the public educational resources of a district.

The statistical returns of public elementary education for the year ending 31st August 1900 show that while the population of England and Wales was 32,526,075, there were 31,313 separate departments under head teachers, of which 4060 were for boys, 3912 for girls, 15,300 for boys and girls (mixed), and 8041 for infants only. The total numbers on the register were: in Church of England schools, 2,300,150; in Wesleyan schools, 156,666; in Roman Catholic schools, 316,769; in British and other unsectarian schools, 269,421; and in schools under School Boards, 2,662,669. Thus the total of registered scholars is 5,705,675, of whom only 6823 were 15 years of age and over. Accommodation was provided for 6,544,092, or about 20·11 per cent. of the estimated population. But the total average attendance was 4,687,646. The staff of teachers was composed of 64,038 certificated masters or mistresses, 32,436 adult assistants, 29,393 pupil teachers, and 17,512 additional assistants.

There are at present no data from which similar statistics can be compiled respecting secondary schools.

**Secondary instruction.**

Experience has proved that the differentiation of primary and secondary and higher instruction cannot be determined by enumerating the subjects proper to be taught under each head. The true distinction is to be found by considering the probable age to which the period of instruction is to be extended. A course of educational discipline which is to end at the age of fourteen is a primary or elementary course. The school which seeks to retain its pupil to the age of sixteen or seventeen, and to prepare him to enter a skilled trade or one of the minor professions, is a secondary or intermediate school; and one which has a curriculum designed to suit the requirements of a youth till the nineteenth year, and to qualify him for entrance to a University or one of the learned professions, is an academic school of the highest educational rank. In various degrees, science, technology, manual instruction, classics, a modern language, history, geography, and mathematics may enter into the curriculum of all three; but the character of the teaching must in the main be dominated by the length of the school-life. Local circumstances and the probable destination of the majority of the scholars will rightly influence the choice and the co-ordination of subjects; but we may conclude, generally, that whatever may be taught honestly and without pretension within the limits of age may be regarded as a legitimate part of a primary, a secondary, or a high school course. Of Greek, for example, it may be safely said that, as a rule, it could not be wisely introduced as a subject either into a primary or an intermediate school, because in such a school there would be no chance of carrying the course of instruction to the fruit-bearing stage; but otherwise there is no good reason for excluding from a school of any one of the three grades the elements at least of some subject which will stimulate the appetite for self-improvement and serve as a good foundation for further acquisition after leaving school.

The existing provision for secondary instruction in England has been hitherto furnished chiefly (*a*) by endowed grammar schools, (*b*) by proprietary schools established by religious bodies or public companies, and (*c*) by private enterprise. An inquiry instituted by the Education Department in 1898 with a view to ascertain the number of pupils in public and private, secondary and other schools in England, not being public elementary or technical schools, resulted in a report to Parliament which was very significant of the varied and incoherent character of the

provision made for secondary instruction. The report says:—

"Some are boarding schools, some are only for day-scholars. Some are the property of private individuals or of partners in private enterprise; some are controlled by committees representing bodies of subscribers; some are the property of companies formed under articles of association with limited liability; some are controlled by local public authorities; some are regulated by Royal Charter, by Act of Parliament, by scheme under the Charitable Trusts Act or under the Endowed Schools Acts, or by some other legal instrument. Some are for boys only, some for girls only, some for both boys and girls. But as there is no general system of inspection applying to all the schools alike, it is not possible, with any approach to accuracy, to classify the whole number of schools, private and public, into grades of educational service. Nor is there in existence any list or register of these schools which pretends to be exhaustive. The whole subject is exceedingly obscure and has never been brought within the scope of comprehensive statistical inquiry."

The statistics in this return are based on information from 6309 schools, of which 1958 are for boys, 3273 for girls, and 1078 are mixed. The total number of boys was 158,502, and of girls 133,642. In 343 schools—224 for boys, with 13,248 scholars; 101 for girls, with 3864 scholars; and 18 mixed, with 2147 scholars—no day pupils were admitted.

***Endowments.*** Endowments have furnished from the earliest times a larger part of the provision for education in England than in any other country. But it is only within the present generation that a systematic attempt has been made to bring them under control and to provide a special tribunal for dealing with them. Before the Reformation there were schools attached to monasteries, chantries, cathedrals, and guilds; and the education given in them was chiefly directed to the training of choristers or priests. The description given by Mr J. B. Mullinger (in *The Schools of Charles the Great*) applies, not inaptly, to the schools attached to religious houses in England before the time of Henry VIII.: "They were designed mainly for the monastic life: boys were taught to read, that they might study the Bible and understand the services; to write, that they might multiply copies of the sacred books; to understand music, that they might give with due effect the Ambrosian chant. Even arithmetic found a place in the course of instruction, mainly on the plea that it enabled the learner to understand the *Computus*, and to calculate the return of Easter and the festivals." Mr A. F. Leach, whose industry has unearthed the names of 200 such schools, does not in his well-known book, *English Schools at the Reformation*, enable us to tell to what extent these schools were available for laymen, or how far they helped to provide general liberal education. Among them Winchester and Eton are the only notable survivors. The dissolution of monasteries and the policy of the Protector Somerset, under Edward VI., caused many of these schools to disappear in their old form; but a resolute effort was made to liberate them from purely ecclesiastical control, to re-establish them on a new footing, and to provide by these means a liberal education for all classes. The reign of Henry VIII. witnessed the foundation of 63 grammar schools; that of Edward VI., 51; that of Mary, 19; that of Elizabeth, 138; of James I., 84; and of Charles I., 59. The general characteristic of these schools was the provision in them for teaching the Latin and Greek languages, and for encouraging quick-witted and diligent learners in all classes of the community to qualify themselves for entrance to the Universities. After the time of the Commonwealth, and especially in the time of William and Anne, scholastic endowments took a new form, and were directed rather to the establishment of charity schools for the children of the poor than to the encouragement of liberal studies in the community at large. The 18th century endowments provided, in what were popularly called charity schools, gratuitous instruction of a very elementary kind, besides clothing and apprentice premiums for the children of the poor. These schools were in almost every case closely connected with the Established Church, and designed to attach scholars to that communion. Lord Brougham in 1816 persuaded Parliament to make an elaborate inquiry into the condition and resources of endowed charities generally, and the reports made in that and the following years gave many particulars respecting the incomes of the several trusts and the way in which they were administered. But the Commissioners to whom the work was entrusted were not charged with the duty of reporting on the educational efficiency of the schools. It was not till the year 1865 that the first serious attempt was made by the Legislature to ascertain the condition of secondary education and to take measures for its improvement. Two previous Commissions—that of Lord Clarendon in 1861 and that of the Duke of Newcastle in 1859—had reported, the former on the nine great foundations known *par excellence* as the "public schools"—Eton, Harrow, Winchester, Shrewsbury, St Paul's, Westminster, Merchant Taylors', Charterhouse, and Rugby—and the latter on the condition of popular or elementary education. Between these two there was a wide field for investigation and report, which was entrusted to the Schools Inquiry Commission of 1865. This body, under the presidency of Lord Taunton, made, with the assistance of Sir Stafford Northcote, Dr Temple, Matthew Arnold, and others, an elaborate investigation into the whole subject and an estimate of the provision then afforded, not only by endowed foundations, but also by private and proprietary establishments, for education other than elementary. The general character of the report, so far as ancient endowments were concerned, was extremely disappointing. A large number of the grammar schools were found to be in a feeble or decaying condition. The writer of this article was Assistant-Commissioner for the purpose of this inquiry, and his testimony, confirmed by that of all his colleagues, was that the number of scholars who were receiving the sort of classical education contemplated by the founders was very small and was steadily decreasing; that the general instruction in other subjects was seriously defective; and that the existence of statutes prescribing the ancient learning often served as a reason for withholding any modern addition to it. The causes of this deterioration were carefully examined and reported on by the Commission. They were declared to be (1) the faulty composition of the governing bodies, who were often little groups of persons renewing the trusts from time to time by co-optation, and in no wise representative of local wishes or needs; (2) the system of freehold masterships, which made it nearly impossible to remove incompetent teachers or to effect improvement; (3) the absence of any public or other supervising authority to ensure efficiency; and (4) the haphazard distribution of endowments, often in places where they were least suited to the requirements of the population. The elaborate reports of this Commission made a great impression on the public. They revealed a lamentable state of decay and uselessness in regard to many of the ancient "classical" foundations; they showed the supply of good intermediate schools, whether private or public, to be wholly inadequate; and they urged the necessity for legislation, to correct the abuses and revise the schemes of the grammar schools, and to co-ordinate, extend and improve, and bring under public supervision the work done by local and private bodies. The Endowed Schools Bill, brought into Parliament by Mr Forster in 1869, was the immediate fruit of this report. Its author contemplated a large and comprehensive measure

for the organization of secondary education. But the Bill consisted of two parts: the first calling into existence an executive body—the Endowed Schools Commission—to frame new schemes for educational endowments generally; and the second providing for the creation of local authorities and a central authority, also for a register of qualified teachers, and for the due examination and supervision of all intermediate and secondary schools, whether private or public. Of this great and statesmanlike proposal, the first part only received the sanction of Parliament, and the second was never revived. But the Endowed Schools Act—at first administered by a separate body of Commissioners, created *ad hoc*, under the presidency of Lord Lyttelton; and afterwards, in 1874, by a department of the Charity Commission—proved during the last quarter of the 19th century to be one of the most fruitful and most beneficial measures ever passed by Parliament. Under it new schemes were framed, which restored the vitality of hundreds of ancient and feeble endowed schools: governing bodies were reconstituted; obsolete and outworn restrictions were removed; freehold masterships were abolished; scholarships and free places, obtainable by merit only, were substituted for nominations by private favour and patronage; and many valuable reforms were effected in general harmony with the recommendations of the Schools Inquiry Report, which was, in fact, referred to in the preamble of the Act, and which serves as the key to the general policy which the Commissioners were enjoined to adopt. According to a return furnished by the Charity Commissioners to Parliament, schemes under the Endowed School Acts have provided for the reconstitution of 902 educational foundations in England, and received the Royal assent, since the passing of the Act of 1869. In the case of 203 charities which in their origin were partly educational and partly eleemosynary or religious, schemes for the due apportionment of the revenue to educational and non-educational objects respectively were framed so as to apply funds, in the form of scholarships or otherwise, to the improvement of education in the districts concerned. A later Royal Commission on Secondary Instruction, which was charged in 1894 with the duty of making a new inquiry, and which was presided over by Professor Bryce, himself one of the ablest and most influential of the Assistant-Commissioners under Lord Taunton's inquiry, brought down the history of the facts to more recent times, and made elaborate recommendations with a view to a more complete reorganization of secondary instruction in the light of the new resources and requirements of the times. It estimated the total annual value of the endowments applicable to secondary education in England at £735,000, excluding the value of sites and buildings. The principal legislative result of this Commission was seen in the enactment in 1899 of the statute creating a Board of Education for England and Wales, which took the place of the Education Department, the Science and Art Department, and also of the Charity Commission and the Board of Agriculture in matters appearing to the Sovereign "to relate to education." The Act abolishes the office of Vice-President of the Council, and the Board is to consist of a President, and of the Lord President of the Council (unless he is appointed President of the Board), the principal Secretaries of State, the First Commissioner of the Treasury, and the Chancellor of the Exchequer. With this Board is associated a Consultative Committee consisting, as to not less than two-thirds, of persons qualified to represent the views of University and other bodies interested in education, for the purpose (1) of framing a register of qualified teachers, and (2) of advising the Board of Education on any matter referred to the committee by the Board.

*Wales.*

The educational requirements of the Principality of Wales were dealt with in accordance with the recommendations of a special Royal Commission, which resulted in the enactment in 1889 of the Welsh Intermediate Education Act, providing for the creation in every county in Wales and in the county of Monmouth of a Joint-Education Committee, to consist of three persons nominated by the County Council, and two others, "being persons well acquainted with the condition of Wales and with the wants of the people," to be nominated by the Lord President of the Council. To these Education Committees is entrusted the duty of framing schemes for the establishment of intermediate and technical schools, for the right application of endowments, and for administering a contribution out of the county rate for the purposes of intermediate education generally. This Act has exercised a marked influence in the Principality, has multiplied secondary schools, and has been received with much favour by the inhabitants. In 1899 the Central Welsh Board was able to report that they had examined and inspected 93 intermediate schools, under the charge of 72 headmasters and 21 headmistresses, and that 7390 scholars (3877 boys and 3513 girls) were in attendance in these schools. The subsequent grant of a charter to the Welsh University, with which are federated the Colleges of Bangor, Aberystwyth, and Cardiff, has gone far to complete the equipment of Wales in the department of higher education.

*The University local examinations.*

In several notable ways the ancient Universities of Oxford and Cambridge have in recent years sought to enlarge the range of their intellectual influence beyond the traditional academic studies and discipline, and have exerted themselves with great effect to improve secondary schools. In 1857 the University of Oxford established a scheme for annual examinations of persons not members of the University. This step was taken chiefly at the instance of Sir Thomas Acland and Dr Temple, afterwards Archbishop of Canterbury, and in the following year a similar scheme of external examinations was adopted by the Senate of the University of Cambridge. Local examinations were established, and during the first seven years boys only were admitted. Each University offered two forms of certificate, the one for junior and the other for senior candidates. Besides the ordinary subjects of a good school course, these examinations offer a wide range of option, "in order to give as free a scope as possible to the development of schools belonging to different types." The far-reaching effect of these open examinations on intermediate schools, and on the aims and plans of their teachers, may be partly estimated by the fact that the report of the *Oxford Delegacy* for 1900 shows that in that year the total number of candidates examined was 9772, of whom 3391 (1739 boys and 1652 girls) were presented at the preliminary examination, 4455 (2590 boys and 1865 girls) were juniors, and 1926 (636 boys and 1290 girls) were senior candidates. The total number who satisfied the examiners was 6265, the numbers of the two sexes being nearly equal. Statistics for 1900 from the University of Cambridge show that examinations were held at 238 centres for boys and 221 for girls: 16,247 candidates presented themselves for examination, of whom 3423 boys and 2158 girls were entered for the preliminary examination, 5414 boys and 2965 girls under sixteen for the junior examination, and 921 boys and 1366 girls for the senior. The failures at the preliminary and at the junior examinations vary from 22 to 26 per cent., and at the examination for senior candidates under nineteen, from 23·8 to 29. Both at Cambridge and at Oxford arrangements have been made for the inspection and examination of schools, and a Joint Board of Examiners has been established by the

Universities for awarding to a scholar in a secondary or higher school a leaving certificate, which may be regarded either as a *terminus ad quem*, testifying that the scholar has reached a fair standard of general proficiency, or as a *terminus a quo*, serving as an entrance examination to the University, and accepted by nearly all the colleges of Oxford and Cambridge as an equivalent for a matriculation test. These particulars do not, however, furnish an adequate estimate of the influence which the ancient Universities have exercised on schools at a distance from academic centres. That influence has helped largely to widen and improve the standard of education in the schools, to encourage students, to give them a truer estimate of their own acquirements, and to give new suggestions and stimulus to teachers. The general confidence in the fairness of the examinations may safely be said to increase year by year.

**University extension.**

The Oxford Royal Commission of 1850, which reported in 1853, discussed several schemes for extending the usefulness of the University—*e.g.*, the establishment of new halls, as independent societies or in connexion with colleges; the permission to undergraduates to lodge in private houses, and to become members of the University; and the admission to professorial lectures of persons not matriculated members of the University. On these points the recommendations of the Commissioners were favourable, and had the effect of leading speedily to desirable reforms. On the thorny question of the abolition of religious tests at matriculation and graduation the Commissioners abstained from direct recommendation, although they expressed their "conviction that the imposition of subscription in the manner in which it was then imposed in the University of Oxford habituates the mind to give a careless assent to truths which it has never considered, and naturally leads to sophistry in the interpretation of solemn obligations." It was not till 1871 that full legislative effect was given to these views by the abolition of religious tests for the higher degrees, except theology, the obligation to sign the Thirty-nine Articles at matriculation having been previously removed in 1854. Another proposal by Mr Sewell for founding, by way of experiment, at Manchester and Birmingham, and in conjunction with Cambridge, local centres of academic teaching for persons who resided at a distance from the Universities, was considered by the Commissioners, but was not embodied in their recommendations. The project, however, was not allowed to drop. Lord Arthur Hervey, afterwards Bishop of Bath and Wells, put forth in 1855 a pamphlet urging the University to supply the literary and scientific and mechanics' institutions of Great Britain and Ireland with lecturers from the Universities, and so to furnish to the students more systematic and more continuous courses of instruction than the isolated popular lectures commonly given in these institutions. But it is to Professor Stuart of Cambridge that the honour of taking the first practical step in this new direction must be ascribed. In 1867 he gave several courses of scientific lectures to ladies at Leeds, Liverpool, Manchester, and Sheffield, on the invitation of the North of England Council for Promoting the Higher Education of Women, and in 1871 he addressed a letter to the resident members of the University of Cambridge describing his experience, and urging strongly that the Universities were not local clusters of private establishments, but national institutions, and that they should seek to enlarge the scope of their intellectual influence by taking up the question of "University extension" in a serious spirit. A syndicate was appointed in 1872 to consider the whole subject, and in the following year it reported in favour of adopting for an experimental period the proposed new scheme of local lectures. In 1876 a society was founded in London, under the presidency of Mr (afterwards Lord) Goschen, for organizing, with the help of representatives of the three Universities of Oxford, Cambridge, and London, the scheme of University extension lectures for the metropolis and its neighbourhood. At the second Oxford University Commission in 1877 evidence was given by Dr Jowett, afterwards Master of Balliol, in favour of the establishment of an office, and the appointment by the University of a secretary for University extension. He further suggested that the tenure of non-resident fellowships should be extended in the case of persons taking or holding professorships in the large towns. In the following year, 1878, the scheme was formally established, and Mr Arthur Acland, afterwards Vice-President of the Committee of Council, was appointed as the first secretary to the Delegacy. From that time the system has continued to develop steadily, with increasing public favour and usefulness, and with friendly co-operation and division of labour on the part of the two Universities. By degrees lectures became supplemented by class-work and the systematic direction of private reading. In 1885 travelling libraries were formed; and in 1888 the first of a most successful series of summer meetings, to assemble at Oxford and Cambridge in the long vacation in alternate years, was held at Oxford. At two or three centres—notably at Exeter and at Colchester—a strong local desire has had the effect of establishing a permanent college in connexion with the University. In a single session 192 courses of lectures were delivered in connexion with Oxford, 135 with Cambridge, 130 with London, and 7 with the Victoria University, giving a total of 464 courses, the number of lectures in a course varying from 8 to 12. The total of lectures in that session was 4408. In the same session 20,148 persons attended the Oxford courses, 10,947 the Cambridge courses, 12,923 the London courses, and 910 the Victoria courses. Besides the 1100 members who attended the Oxford summer meeting, there was thus a total of 46,028 attendants at the courses, the number of lecturers employed being 88.

**Provincial colleges.**

To this record of increasing activity in the older Universities is to be added the remarkable growth of local colleges of University rank in some of the most important industrial towns. In 1846 Mr Owens endowed with nearly £100,000 the college at Manchester which bears his name, in 1874 the Yorkshire College of Science at Leeds, and in 1878 University College at Liverpool, were founded; and these three institutions became federated, and received in 1880 a Royal Charter under the name of the Victoria University. The Durham College of Science was founded at Newcastle-on-Tyne in 1871, and has since become incorporated with the University of Durham. Mason College, Birmingham, was founded in 1875, and has been absorbed in the new University of Birmingham, which received a charter of incorporation in 1900. University College, Bristol, was established in 1876; Firth College, Sheffield, in 1879; and University College, Nottingham, in 1881, the last two owing their origin in large measure to the stimulus afforded by successful courses of local "extension" lectures. No one of these institutions was founded by Government. All of them owe their origin to local patriotism, and to the large gifts which have been made to them by rich citizens; the equipment in Manchester, Liverpool, Nottingham, and Newcastle being on an exceptionally liberal scale. But a Treasury Minute was issued in 1889 containing a provision that £15,000 a year should be distributed among these and similar colleges in sums varying from £1200 to £1800 a year each. King's College and University College and Bedford College for Women, in London, were admitted to participate

in this grant. There can be little doubt that all these modern developments of academic life and usefulness have supplemented the activity of the ancient Universities in a remarkably effective way. The provincial colleges are yearly adding to the number of their students. Their freedom from traditional restrictions has enabled them to adapt their courses of study to the industrial requirements of the several communities in which they are placed; and hence practical and experimental science in its special bearing on the manufacturing interests of the district has taken a conspicuous place in some of the programmes of the local colleges. Yet in all of them ample provision is made for the teaching of language, history, and philosophy, and generally for the "humanities," as the basis of a liberal education. Nor would it be right to overlook their indirect effect on the social and intellectual life of the great industrial centres, for this has been scarcely less valuable than the actual teaching given in the colleges themselves. It has long been a subject of concern that many of the richer and some of the more cultivated inhabitants of great manufacturing towns ceased after a time to reside in them, and betook themselves to London or the country. The permanent inhabitants were for the most part absorbed in business, and the lack has been felt of a class of persons engaged in intellectual pursuits, and obliged by the nature of their duties to become habitual residents. The professors of the new provincial colleges form such a class; and experience has shown that they have received cordial welcome, and that their influence on the local society has been generally recognized as a clear gain.

***University education in Ireland.***

The future organization of University education in Ireland is not yet (1901) finally decided, and is still a subject of much controversy in the sister island and in Parliament. A Royal Commission has been engaged in investigating the whole subject. The principal existing provision for academic education in Ireland consists of the ancient University of Trinity College, Dublin, the Royal University founded in 1880, and the Queen's Colleges. The Provost and Fellows of Trinity College were until recently required to be members of the Established Church, and the institution was long regarded as a stronghold of Evangelical Protestantism. But these restrictions and all religious tests have now been abolished. The Royal University consists of a Board empowered by charter to examine students and to confer degrees, but exercises no direct teaching functions. These provisions are not satisfactory to the heads of the Roman Catholic Church, who have made a strong effort to induce the Government to grant a charter to a new Roman Catholic University, which shall be largely under the supervision and influence of the hierarchy of that Church. The question thus raised is of great importance to the whole empire, since by recent legislation all theological tests, whether for the students or for the governing bodies, have been abolished at Oxford and Cambridge and at the Scottish Universities, and since every one of the newer academic institutions which are empowered to confer degrees, either in the United Kingdom or in the Colonies, is wholly unsectarian in its character. The University of Laval, in Lower Canada, is almost the only exception—and not a very important one—to this general statement. Those persons who object to the proposed new departure from all these precedents in the case of the Roman Catholics of Ireland, urge that there is a fundamental difference between a College and a University. While Colleges with a pronounced denominational character deserve full recognition and public aid, a University is something more than a College. It is a chartered corporation empowered to set up a standard of general scholarship and science, and to award degrees and distinctions, such as may have a recognized value in the learned world. In the discharge of this duty it is urged that theological considerations should have no place; and the establishment of a University under the management, and charged with the interests, of a particular Church would be a reactionary step of very serious import in a nation which has deliberately divested all its Universities of their exclusive sectarian privileges, and in which there is not, in fact, an Anglican, a Presbyterian, or a Wesleyan University. Accordingly, a very general opinion has been expressed that, while providing amply to meet the reasonable desire of Roman Catholics to maintain *teaching* institutions adapted to their own needs, the University which is to possess the degree-conferring power should be governed by persons distinguished for learning and science only, and not necessarily identified with a theological creed. It yet remains to be seen how far a compromise on these lines can be arrived at in view not merely of political exigencies, but also of the higher interests of scholarship and of intellectual progress.

***The University of London.***

The reconstitution of the University of London in the year 1900, under the Act of 1898, is a fact of great significance in the history of the higher education in England. That institution was founded in the first year of the reign of Victoria with a view to place the means of University training within the reach of students who were prevented by distance, by the existence of religious tests, or otherwise, from availing themselves of Oxford or Cambridge. At first its scope was limited to two or three colleges in London, and to a small number of provincial colleges; and the Senate was empowered, after due examination, to confer degrees on such students of these colleges as had fulfilled certain conditions of residence. But in the year 1858 a new charter practically abolished the connexion of the University with the affiliated colleges, and empowered the Senate to confer degrees and honours on all candidates, collegiate and non-collegiate alike, who could satisfy the examiners. After that time the University was mainly an examining board; year by year upwards of two thousand young persons presented themselves for matriculation, and the number of degrees conferred in the Faculties of Arts, Laws, Science, Medicine and Surgery steadily increased. A strong desire arose, however, that the Metropolitan University should influence teaching as well as examination, and that it should be brought again, though under altered conditions, into organic connexion with the great teaching bodies of London. After the reports of two Royal Commissions entrusted with the duty of making inquiries on this subject — the first under the presidency of Lord Selborne, in 1882, and the second, in 1892, under Lord Cowper—an Act of Parliament in 1898 reconstituted the University, on the principle that while continuing to discharge all its functions as an examining body for collegiate and non-collegiate students in all parts of the empire, it should also establish closer relations with the great London colleges and medical schools, give to the authorities of those institutions a larger share in the government of the University, and seek in other ways to co-ordinate and control the higher education of London. Statutes designed to give effect to this proposal received the royal assent in the year 1900. These statutes contemplated a wide extension of the usefulness of the University under its new conditions. In particular, they recognized it as a large part of the business of a University to ennoble and liberalize the higher professions generally, without the limitation to Divinity, Law, and Medicine, which have for so many years been regarded as *par excellence* the learned professions. To bring a high standard of general literary

culture to bear on the practice, *e.g.*, of engineering, of commercial and economical science, and of education considered both as an art and as a science, and to aid by means of post-graduate courses the practitioners of these and other callings in their efforts to find a scientific basis for their several professions, is part of the task which awaits the Senate of the reorganized University, and on which they entered under the most hopeful auspices.

But, on the whole, it cannot yet be said that the part played by the English Universities in the higher professions, or in the general culture of the nation, is so important as could be desired. In 1871 Professor Bryce computed that whereas in Germany, with a population of 45 millions, there were 24,187 University students, England, with a population of 26 millions, had fewer than 5500 such students. Notwithstanding all the recent additions to her academic resources, England is still far behind other countries in the provision it makes for University education.

***Continuation schools and polytechnics.***

Successive Acts of Parliament have recognized the age of 14 as the limit of primary education; and the Codes of the Education Department have from time to time prescribed that after passing the "standard" of instruction appropriate to that age, the grants on behalf of a scholar in a day-school should cease to be paid. Evening schools have, however, long been encouraged by special grants to give supplementary instruction to young people who had left the day-school. For a time these grants were made conditional, as in the day-schools, on the passing of the scholars in the examination in elementary subjects. Mr Acland, however, in 1893 framed new regulations for evening continuation schools. The Code of that year gave greater variety of choice to managers in relation to the subjects of instruction, and substituted grants, calculated on the number of hours of regular teaching, for payments on the results of examination. These regulations gave a considerable impetus to the establishment of evening continuation schools, and the report of the Committee of Council (1900) records a total of 6154 such schools or departments, and of 206,335 scholars in average attendance. Of these, the number of boys and men nearly doubles that of girls and women, and the total number of evening scholars in Board schools as distinguished from Voluntary schools is in the ratio of three to two.

In the article on Technical Education will be found particulars respecting the provision which has been made for the encouragement of scientific and manual training in its special relation to skilled industry. A strong feeling had, however, become manifest, that both in the primary schools and in the supplementary evening courses the instruction was too literary in its character, and that the practical side of life—that which is concerned with the training of hand and eye, the use of tools and measurement, and the study of those branches of science which are most nearly related to the arts of life—had been unduly neglected. How far the defects thus apparent could be remedied by an altered curriculum in either the primary or the secondary school, or by the establishment of new and separate agencies, is a question not without difficulty, and one on which neither the public nor the higher educational authorities are yet clearly in accord. The young men and women who have acquired at the elementary school the habit of application and an interest in their own mental improvement, and especially those who desire to devote part of their leisure to the attainment of such scientific, technical, artistic, or literary knowledge as is most closely akin to their own business or profession, form a class for which the provision has hitherto been inadequate, and which sorely needed, and still needs, further help and guidance.

In London part of the help thus needed came from an unexpected quarter. In 1878 a Royal Commission was appointed, with the late Duke of Northumberland as the chairman, for investigating the condition of the City parochial charities. It was proved that many of them had become, under the altered conditions—social and residential—of the present day, obsolete and useless. Doles and Christmas gifts, pensions and apprentice funds, and other like forms of benevolence which had once been of service when the citizens of London lived at their places of business, were no longer needed when the residents had flocked to the suburbs and lost all association with the London parishes. Moreover, the revenues of the charities had in many cases, owing to the greatly increased value of City property, grown out of all proportion to any wants of the few remaining City residents. The Commissioners, *e.g.*, refer to one parish, with a population of only 150 consisting chiefly of bank clerks, in which there was a pension fund of £1800 a year. Accordingly, Parliament in 1883, mainly at the instance of Mr Bryce, passed the City Parochial Charities Act, which empowered a small body of Commissioners, after making due reservation of ecclesiastical and other prior claims, to apply the revenues to other objects of utility more suited to the present needs and circumstances of the London population. The sum of £155,000 was appropriated to the purchase of open spaces and recreation grounds in London and its suburbs, and a like sum to the establishing of Free Libraries and of Polytechnics. Besides the capital sum thus expended, an annual revenue of about £50,000 was retained in the hands of the Commissioners, and has been employed in the maintenance and extension of similar institutions. The People's Palace in Mile End and the Borough Road and Battersea Polytechnics are among the best-known examples of the institutions which have thus been aided. In them provision has been made for evening classes and lectures of a varied and attractive kind; for manual and industrial training in workshops and in class-rooms; for gymnastics, and for field-naturalist, musical, debating, and similar clubs, as well as for drawing and design and other forms of art. There can be little doubt that these institutions, all of which are crowded with students, are exercising an important and increasing influence on the intellectual culture of London, and especially on the career of the more thoughtful and more aspiring of young people engaged in commerce or in manufactures in the City and its environs. Other grants from the fund have been made, and will probably continue to be made, at the discretion of the trustees, in aid of smaller classes and institutes, the colleges for working men and women, and the like useful objects.

Another windfall became available in the year 1890, which had a large influence in extending the opportunities for the literary and the industrial improvement of young men and women after quitting the elementary school. In the previous year the Technical Instruction Act had empowered local authorities to supply, by means of rates, technical or manual instruction, and had defined such instruction as "instruction in the principles of science and art applicable to industries, and in the application of special branches of science and art to specific industries or employments." But in 1890 certain local taxation (customs and excise) duties having been directed to be paid to the same local account as the local taxation probate duty, it became necessary to make legal provision for the distribution and application of the duties so paid. At first it was proposed by the Government to employ a substantial part of this sum in compensating publicans for the loss of their business. But Parliament showed great unwillingness to assent to

such an appropriation of the funds, and, mainly on the initiative of Mr A. H. Acland, the Local Taxation (Customs and Excise) Act was passed, practically permitting the application of the whole fund, after the deduction of a fixed sum reserved for the superannuation of the police, to the encouragement of technical instruction as defined by the Act of 1889. The total annual sum thus available was nearly one million sterling, and it was placed at the disposal of County Councils and County Boroughs, in proportion to the ratable value of the property in the several populations which they represented. The share of London, which in 1890 was £162,572, has since increased, until in the year 1900 it amounted to £225,728, of which £180,000 is allotted to technical education. The County Council appointed a special Board for the administration of this fund, and has applied it in various ways. The estimated expenditure for 1900–1 includes (*a*) Technical departments of Polytechnics, including contributions towards the erection of buildings, £36,650; (*b*) other technical schools and institutes, £24,664; (*c*) establishment and initial equipment of new institutions, £22,000; (*d*) technical departments of public secondary schools, £28,470; (*e*) higher education, £3500; (*f*) county scholarships, £30,362; (*g*) teaching in Art, Science, Technology, and manual instruction, including scholarships and pioneer lectures, £16,506; (*h*) domestic economy, £5874; (*i*) commercial subjects, £4798; (*j*) museums (art examples), £383; and (*k*) expenses of administration, £7860. One of the chief features of the London scheme is the liberal provision of scholarships offered annually by the Technical Education Board. There are 600 junior scholarships open to all London children under thirteen, and carrying with them the right of free education in some approved secondary or technical school, and in addition a gratuity of from £8 to £12. Other scholarships—*e.g.*, intermediate, commercial, art and artizan, domestic economy, horticulture and practical gardening, and cooking—are also provided; the general principles of award being that the scholarships are open to all residents in London, that boys and girls are alike eligible, and that the sum granted is partly expended in the payment of their fees in some school or technical college, and partly in a money payment in aid of the scholars' maintenance during the period of study. The number of such scholarships granted in 1899 was 1710, and the total sum thus expended by the Board was nearly £40,000. Throughout the country the sums of money thus specially assigned by the Act have been employed by the County Councils on educational objects more or less akin to the industrial and commercial requirements of the several districts. Without precedents to guide them in the exercise of their novel trust, many of the Councils have tried various experiments—*e.g.*, in seaports, schools of navigation; in Newcastle and other places where great engineering works existed, the study of mechanical science has been helped, partly by providing laboratories and apparatus and special teachers in existing schools, and partly by scholarships and exhibitions tenable in science colleges; in rural districts, the study of agriculture and horticulture, and the encouragement, by the help of peripatetic lecturers and otherwise, of systematic instruction in dairy work, bee-keeping, or cheese-making. The total effect of this beneficent Act in reviving many local industries, in encouraging educational enterprise and new forms of manual and scientific instruction, has already been powerfully felt, although the full application of the special fund thus received from the Exchequer still yet awaits further experience, and may require some modifications in the plans originally tried.

*Public libraries.*

The influence of the Public Libraries Acts, of which the first was passed mainly at the instance of Mr William Ewart in the session of 1850, has been very extensive and beneficial. At first the maximum rate which the various municipalities were empowered to levy was a halfpenny in the pound, but the Act of 1892 removed this restriction and empowered the inhabitants to determine for themselves the amount which might be applied to this object. A rate of one penny is generally found to suffice, but in Wigan the library rate has reached twopence in the pound. English municipalities were slow to recognize the great intellectual and social advantages of the Free Library, or to avail themselves of the permission given by the Act of 1850. In 1860 there were only twenty-one such libraries and reading-rooms; in 1870 there were thirty-five; in 1880 fifty more were added. In 1890 the total had reached 187; and there are now 340 free libraries in England and Wales. Of these, 36 are in the metropolitan districts. The total number of volumes in use, for reference or for distribution, is about six millions. Manchester furnishes 280,000; Birmingham, 215,000; Liverpool, 200,000; Leeds, 195,000; Sheffield, 110,000; Bristol 90,000; and Nottingham, 85,000. Most of these libraries are housed in costly and convenient buildings provided by the several municipalities, and all of them are visited by increasing numbers of readers. It is becoming more and more evident that the public library is an indispensable adjunct to the other agencies by which primary, secondary, and technical education are being promoted. Within the last few years the growth of public libraries has been stimulated to a large extent by the remarkable munificence of a private citizen. Mr J. Passmore Edwards has devoted more than a quarter of a million sterling to the erection, maintenance, or equipment of libraries, picture galleries, or other kindred institutions. He has been singularly fortunate in the wise choice of objects, which are wholly outside the category of ordinary charities, and are all intended in various ways to help forward the intelligence and the social enjoyment of the people.

*Women's education.*

No survey of the educational history of the Victorian era would be complete if it omitted all reference to the remarkable increase of late years in the public and professional activity and in the intellectual influence of women. Access for the first time in English history has been found for them not only to the medical profession, and to high and responsible employments in the Civil Service, but also to many posts in connexion with commerce and with journalism; to engagements as librarians and secretaries, and as superintendents of skilled labour, in gardens, in offices, and in factories. Women have also been employed, both by the Central Education Department and by local Boards, as inspectresses and organizing mistresses. In art also, and in literature, and in scientific research, women have achieved success, and even eminence, to an extent unknown two or three generations ago. Besides new avenues to honourable and lucrative employment in professions and trades, there has been a large increase in the amount and value of the unpaid public services which women are now rendering to the community. Many have become members of School Boards and of Boards of Guardians, trustees of endowed foundations, or skilled administrators of charity. Some have been placed by the Government on various Royal Commissions of Inquiry; three were included in the Consultative Committee to be attached to the new Board of Education; and three have recently been nominated as members of the Senate of the University of London. In all of these ways, and in many others, women are taking daily a larger and more important share in the public life of England, and are rendering signal service. It cannot be doubted that in this way the whole

community has been enriched by the application of powers and talents which, under other conditions, would have remained undiscovered and therefore unused; and that in enlarging the range of intellectual interests open to women, they themselves have found new opportunities of useful activity, and new means of adding to the dignity and the happiness of their lives.

But all these important changes have presupposed as essential conditions increased educational advantages, and a higher standard of what is suitable and necessary for the instruction of girls. In the sphere of primary education the action of the Education Department has from the first been favourable. The standards of instruction which have been prescribed from time to time have, except so far as needlework is concerned, been practically the same for girls as for boys. The qualifications of pupil teachers and for head teachers of both sexes have, with a few unimportant exceptions, been identical. The total number of certificated mistresses recognized by the Board of Education is 36,435, as compared with 23,439 certificated schoolmasters; while of assistant teachers 4065 are young men and 22,671 are young women. This disproportion has a tendency to increase year by year, as a larger share in elementary work falls into the hands of female teachers. In this connexion it is interesting to consider the experience of the United States. The statistics of the American Bureau of Education include teachers of all ranks, from the kindergarten to the higher colleges and universities, and the last returns show that in all 131,750 men and 277,443 women were engaged in education, and that the proportion of men to women had since 1870 steadily diminished. In 1870 it was 42 per cent., in 1889 it had fallen to 34·5 per cent., and in 1898 to 32 per cent. In the Department of Secondary Education in England a like change is taking place. Formerly all the more pretentious private "seminaries" for girls prided themselves on the number of visiting masters, who gave lessons in arithmetic, or history, or music, or astronomy and the use of the globes. But in just the proportion in which a liberal education has become accessible to women, the need for masters is fast disappearing; since it is a familiar fact of experience that, given an equal amount of knowledge, women are likely to be better teachers of the young than men, as they have greater natural aptitude and a finer intuitive insight, enabling them to know the needs of childhood and to adapt lessons to these needs. What they know they can teach. The only reason why this fact has been so slowly recognized, is that the opportunities for obtaining sound and thorough scholarship were so long withheld. Of the public measures that have affected the intermediate education of women in England, one of the most effective was the report of the Schools Inquiry Commission in 1867, in which the defects of girls' secondary instruction were characterized as "want of thoroughness and foundation; want of system; slovenliness and showy superficiality; inattention to rudiments; undue time given to accomplishments, and those not taught intelligently or in any scientific manner; and a complete absence of proper organization." In the Endowed Schools Act of 1869 there was inserted the 12th clause, "In framing schemes under this Act provision shall be made, as far as conveniently may be, for extending to girls the benefits of endowments." The last report of the Charity Commission shows that, in obedience to this clause, eighty-two new secondary schools for girls had been established, and that sixty-two other schemes contain *inter alia* special provisions for enabling girls to share, either by scholarships or otherwise, the advantage of ancient grammar school endowments. Schemes for some of the wealthier foundations, notably St Paul's School and Christ's Hospital, provide liberally for the future application of large funds to the maintenance of secondary and higher schools for girls. The opening of the local examinations of the two Universities to girls has already been referred to, and has had a marked effect in raising the standard of efficiency in the intermediate schools for girls. In 1874, when the public had been much impressed with the serious revelations of the Schools Inquiry Commission, Mrs William Grey and her sister Miss Shirreff, with the subsequent aid of Miss Mary Gurney, founded the Girls' Public Day School Company, with a view to familiarize the public with an improved type of schools. The experiment has proved remarkably successful. The company possessed in 1900 thirty-three high schools, with upwards of 7000 pupils; and its example has been followed in many places, where schools of a similar character, under the care of qualified teachers and the government of responsible public bodies, have been founded independently. Before this effort, two of the most remarkable institutions for the secondary instruction of girls had furnished the pattern which the company to a large extent followed. The Ladies' College at Cheltenham had been founded in 1854, and under the skilful supervision of Miss Dorothea Beale had grown into one of the most important institutions in England. It is unrivalled in the completeness of its material equipment, in the qualifications of its teachers, and in the successes it has won in all the most important examinations open to women. Including its kindergarten and its training department for teachers, it numbers upwards of nine hundred pupils, of whom about half are boarders, and the rest are the daughters of residents in Cheltenham, many of whom have settled in the town and neighbourhood for the express purpose of availing themselves of the exceptional advantages which the college offers. The North London Collegiate School for Girls, which originated in the remarkable efforts of Miss Frances Buss in the year 1850, and which has gradually become a public foundation school of a high type, has served as a model, since largely imitated by the founders of local high schools for girls. Bedford College and Queen's College in London were established in 1848, with a view to place opportunities of higher education within reach of girls who desired to prolong their education beyond the ordinary term of school-life; and the names of Professor F. D. Maurice, Charles Kingsley, Miss Anna Swanwick, and Miss Frances Martin have been honourably associated with the early successes of these institutions.

But the most important aid which women have received in regard to advanced education has been furnished by the English and Scottish Universities. In 1867 the first attempt was made to establish in England a college of University rank for women. A house was taken at Hitchin, midway between London and Cambridge, and fitted for the reception of six students. In 1873 the college was removed to new premises at Girton, near Cambridge. By successive additions it has been enabled to receive 150 students, and it will probably be still further enlarged. From the first the governing body of Girton College, prominent upon which were Miss Emily Davies and Lady Stanley of Alderley, sought to avail itself to the full of the academic education provided by the University, and to maintain the standard of learning in the college on the same level as that prescribed for men. In 1871 a similar enterprise was started under the care of Miss A. J. Clough, who took a house at Cambridge to prepare students for such examinations as were then open to women, and in this way established the institution known as Newnham College, which has been from from time to time enlarged, until it contains three halls of residence and accommoda-

tion for 150 students. Both colleges are thriving, and have always been well filled. In some minor respects the arrangements of Newnham are more elastic than those of Girton, since its students are not all required to pass through the regular University curriculum. But from the first both institutions have sought recognition from the University; and steps were taken to obtain for the students of the colleges admission to the examinations for degrees. At first personal application was made by Girton to the examiners, with the cognizance of the Council of the Senate, requesting them to examine some of the college students, and to conduct the *vivâ voce* examination, reporting on the attainments of the students according to the University standard; and up to 1881 degree examinations were carried on by the courtesy of the examiners, on an informal but strictly regular system, simultaneously with those of undergraduates of the University. In 1881 the Senate by formal grace extended to women the "Little-go" and the Honour examinations, though not the examination for the ordinary degree; and since that date the students of both colleges have been admissible to the Previous and to the Tripos examinations, and have received from the University a formal certificate attesting the result of the examination, though not at present conferring the actual academic title. The total number of students admitted to Girton from the time the college was opened till 1901 was 757, of whom 496 obtained honours according to the Cambridge University standard, 146 having passed in the Classical and 134 in the Mathematical Tripos, and others in History, Mediæval and Modern Languages, or Natural Science. Newnham College also secured between 1880 and 1900 upwards of 500 places in the Tripos examination. In the single year 1899, 12 students passed in the first class, 29 in the second, and 20 in the third, besides 3 students who attained the standard qualifying for the ordinary degree.

The University of Oxford has followed the example of Cambridge somewhat slowly and gradually, but with very notable results. Three colleges for female students have been established—Somerville College, Lady Margaret Hall, and St Hugh's Hall. The University instituted special examinations for women in 1875; but in 1884 these special examinations were practically abolished, and a statute was passed in Convocation opening to women the ordinary Honour Moderations (Classics and Mathematics), and the Final Honour Schools of Mathematics, Natural Science, and Modern History. In 1886 women were admitted to Responsions, in 1888 to the Honour School of *Literæ Humaniores*, in 1890 to the Honour School of Jurisprudence, in 1893 to the Honour Schools of Theology and of Oriental Studies, and in 1894 to the remaining examinations for the degree of B.A. In all, between 1884 and 1900, 56 women presented themselves for honours at moderations in Classics, and 17 in Mathematics; for final honours, 146 in Modern History, 22 in Natural Science, 7 in Mathematics, 17 in *Literæ Humaniores*, 2 in Jurisprudence, 22 in English Language and Literature, and 47 in Modern Languages; of these, 56 passed in the first class and 119 in the second at the Final Honour School.

Holloway College, near Egham, founded and munificently endowed by the late Mr Thomas Holloway in 1876, has taken high rank as a college for women, and is recognized as one of the schools of the University of London in the Faculties of Arts and Science. In the year 1899 it had 108 students, and a large staff of professors and lecturers. It is exceptionally rich in scholarships, of which 12 are open for competition on entrance, and 2 others for students of merit in the college.

The University of London, as a comparatively modern institution, unhampered by tradition or ancient statutes, has found itself free to take a step which has at present proved impossible in the two older Universities. In 1878 the Senate, with the concurrence of Convocation, obtained from the Crown a charter enabling persons of both sexes to graduate in all the Faculties on perfectly equal terms. Up to the year 1900, 5185 women passed the examination for Matriculation, 1383 the Intermediate examination in Arts; 861 obtained the full degree of B.A., and 63 that of M.A. In the Faculty of Science, 266 passed the Intermediate examination, and 145 obtained the degree of B.Sc., while 9 proceeded to the D.Sc. degree. In Medicine, 74 obtained the degree of M.B., 21 that of M.D., and 23 that of Bachelor in Surgery.

The example of the London University has since been followed by the Victoria University, by the Scottish and Welsh Universities, and by Durham University, with which is now incorporated the flourishing College of Science in Newcastle-on-Tyne. The University of Birmingham also receives as students, and admits as candidates for degrees, women as well as men. Proposals have sometimes been put forth by influential persons for establishing a women's University. But they have not proved acceptable to academic or public authorities, nor indeed to women themselves. Women's *colleges* supply already a great want, and they will probably increase in number and in usefulness. But for a women's *University*, which shall give a separate feminine degree, and set up a special standard of liberal education supposed to be adapted to the intellectual needs of women only, there is at present no general demand. Nor is it probable that such a demand will arise in any practical form until philosophy and experience shall have enabled us to differentiate the mental characteristics of men and of women, and to determine in what departments of human knowledge each of them should be encouraged or required to excel. Meanwhile the chief advocates of the intellectual progress of women are content to ask the Universities to afford access to the same variety of optional courses, and the same rigorous tests of attainment which experience has shown to be needed by men, and then to leave female students at liberty to exercise their own choice. Hitherto the British Universities have given a generous response to this appeal, and there can be little doubt that in any future development of academic institutions in England the claims of women to share in the highest intellectual privileges will be more and more recognized.

***A notable endowment for women's higher education.***

It is right to record here a recent and significant fact in the history of educational endowments. Mr Pfeiffer, a London merchant, and his wife, Mrs Emily Pfeiffer, determined in 1884 to bequeath the whole of their residuary estate, amounting to nearly £70,000, "to charities and educational establishments on behalf of women, and of women solely"; and the will expressly specified that what the testator desired most was the intellectual or professional training of women, "theirs being to my mind the great influence of the future." The persons entrusted with the distribution of this fund were the Vice-President of the Council of Education, Miss Anna Swanwick, and the writer of this article. The bequest became available in 1890, and under the sanction of the Court was distributed, in sums varying from £2000 to £5000, to Girton and Newnham and Somerville Colleges, the training colleges for secondary teachers at Cambridge and in London, Bedford and Queen's Colleges, the Halls of Residence for women students attached to Universities and Colleges in London, Edinburgh, Dublin, Cardiff,

St Andrews, and Aberystwyth, the London School of Medicine for Women, the College for Working Women, and similar institutions. In this way, either by the erection of new buildings or by the establishment of studentships and prizes, substantial help has been given to some of the most promising of the modern enterprises by which the intellectual advance of women has been stimulated in the United Kingdom.

*Training of teachers.*

Recent years have witnessed a great change in the state of public opinion in regard to the professional qualifications of teachers. That teaching is a fine art, that underneath its rules and processes there lie principles which deserve investigation, and that the skilled practitioner is distinguished from the unskilled by his knowledge of the history and philosophy of his art, and of the reasons why some methods of instruction and discipline are right and others are wrong, are truths which are being slowly recognized by public authorities, as well as by teachers themselves. The full appreciation of the importance of training began at the lower end of the social scale. Shuttleworth and Tufnell in 1846 urged the necessity of special training for the primary teacher, and hoped to establish State Training Colleges to supply this want. The opposition of the Churches prevented the fulfilment of this design, and the one college at Battersea which was founded as an experiment was soon transferred to the National Society. Before this, Bell and Lancaster had made arrangements in their model schools for the reception of a few young people to learn the system by practice in the schoolroom, and to pursue their studies in the after hours. In Glasgow, David Stow, who founded in 1826 the Normal Seminary which afterwards became the Free Church College, was one of the first to insist on the need of systematic professional preparation. The religious bodies in England, notably the Established Church, availed themselves promptly of the failure of the central Government, and 12 diocesan colleges for men and 16 for women have been since established. In 1854 the British and Foreign School Society placed their establishments at the Borough Road and Stockwell on a collegiate footing, and subsequently founded other colleges at Swansea, at Bangor, at Darlington and Saffron Walden; the Roman Catholic Church provided two colleges for women and one for men; and the Wesleyans two—one for students of each sex. Other training institutions have since come into being. The newly founded provincial colleges of University rank have been invited by the Education Department to attach normal classes to their ordinary course, and to make provision for special training and for suitable practice in schools for those of their students who desired to become teachers, but who pursue their general literary and scientific studies in common with other learners who are not intending to enter the profession. Thus the Education Department came to recognize two kinds of training institutions—the residential colleges of the old type, and the day colleges attached to institutions of University rank. Both are subsidized by liberal grants from the Treasury, and are regularly inspected. The report of the Department for 1899 showed that in that year there were 3700 students in residence and 1230 day students. As the period of training is two years, these figures show a yearly increment to the ranks of certificated teachers of about 2400. But this supply is insufficient to meet the annual demand; and 28·57 per cent. of masters and 51·18 per cent. of mistresses still enter the profession by serving as assistants and passing the certificate examination, but without receiving regular collegiate training. There is thus still need of more training school accommodation, and this is being gradually furnished by voluntary and municipal effort. But regular provision for training has hitherto been available for elementary teachers only. Fashions, either in social usages or in dress, descend readily from one stratum of society to a lower, but they seldom ascend; and the accident which caused the earliest pedagogic experiments to be tried in connexion with the teachers of primary schools has led to a general impression that training was needed for lower but not for higher educational work. Hence it has happened that only slowly, and not without reluctance, teachers and public authorities have come to the conclusion that a like training and discipline might with great advantage be made available in higher and intermediate schools. The University of Cambridge in 1879 took a step which has had far-reaching consequences in this direction. It entrusted a special syndicate with the duty of providing public lectures on educational principles and practice, and of examining candidates for a special teacher's diploma. Since 1882 the University has awarded certificates in the theory, history, and practice of education to 60 men and 1477 women. The University of London in 1883, and the Victoria University in 1895, instituted similar examinations; and in such great provincial colleges of University rank as have been founded in Manchester, Liverpool, Newcastle, Bristol, Birmingham, Nottingham, Leeds, and Cardiff, as well as in the older Universities, efforts are already made to provide courses of special preparation for secondary as well as for primary teachers. More recently, the University of Oxford has adopted a scheme for granting certificates in education. This scheme, while providing special courses of instruction and a comprehensive syllabus of examination, insists on evidence of regular and continuous practice in teaching under due observation as an indispensable qualification for the University diploma. The two permanent institutions for the training of high school mistresses are the Maria Grey Training College, near London, and the Training College at Cambridge; but several of the leading high schools for girls—notably the Ladies' College at Cheltenham and the Datchelor School at Camberwell—have attached to themselves a training department which is becoming year by year more efficient. These institutions prepare their students for the Teacher's Diploma of either Cambridge or London University. All these movements are symptoms of an increased sense of the need of skilled training for the teacher's profession, and all will be greatly strengthened and encouraged by the clause in the Board of Education Act of 1899 which provides for a public registration of qualified teachers, and for the gradual elimination from the profession of those who are unqualified. But the question will still remain, How and where are the needful qualifications to be obtained, since the Government has not established a Training College of its own, and since it is hardly to be expected that the want will be supplied by the voluntary efforts of societies or by private initiative? In London and some of the larger towns it is already proposed to apply some of the funds available under the Excise Act to the training of teachers. It is to the Universities chiefly that the public has a right to look for at least a partial solution of this difficult problem. Experience is gradually revealing to us the conditions under which those corporations will be able to take an increasing share in the duty of giving professional training to teachers, and thus to render new and signal services to the State. These conditions are: (1) that the function of the teacher shall be recognized as one of the learned professions, and take honourable rank with Law, Medicine, and Theology; (2) that the University shall provide a Professor of Didactics or Pedagogy, whose duty it shall be, by means of post-graduate courses of study and by requiring systematic practice in the art of teaching under due supervision and criticism, to give to the future schoolmaster both a practi-

cal and a theoretical acquaintance with the principles of his profession; (3) that the University shall institute an examination for all students who may have passed through the prescribed course, and that this examination shall set up a high standard of qualification in regard to the practice and the history of education, and to so much of mental and moral philosophy as stands in the closest relation to teaching, whether considered as an art or as a science. The third of these requirements is already fulfilled by Oxford and Cambridge and by most of the English and Scottish Universities, although there is at present no general agreement as to the ideal standard of professional qualifications, or as to the best way of testing these qualifications. In regard to the second of these conditions, the Universities of Edinburgh and St Andrews were enabled, by means of the fund bequeathed by Dr Andrew Bell, to be the first British Universities to create a Professorship of Education; and the Victoria University has lately taken the bold step of establishing a special Chair, whose occupant shall have the same rank as the other Professors of Science or of the Humanities. But until all three of the conditions here described shall have been fulfilled, the British Universities will fail to exercise their legitimate influence on public education, and will neglect a great opportunity of ennobling and liberalizing the teacher's profession.

**Administrative co-operation.** Among the administrative reforms yet needed there is one which will probably engage the early attention of Parliament. Several of the great departments of the public service are incidentally and in a subordinate sense concerned with education, and are at present in no official relation with the central Board of Education. For example, Marine and Dockyard Schools have long been maintained at the various naval stations by the Board of Admiralty, with a view to supply elementary instruction to the children of the sailors and workmen employed at these stations. The supervision of these schools has for many years been entrusted to the Chaplain of the Fleet and to various naval officers. A like arrangement has long prevailed in the army. The Local Government Board, under which the Poor Laws are administered, is necessarily concerned with the maintenance of schools for all the children whose maintenance is chargeable to the rates, and this Board has its own staff of inspectors, both for workhouses and for workhouse schools. The management of industrial and reformatory schools falls within the province of the Home Office, which is responsible for the efficiency of those institutions, but which is in no sense aided or advised by the Board of Education. The newly-constituted Board of Agriculture also is in a position to exercise much influence over rural education. It is manifest that in all those departments of the public service which have been created for other than educational objects, and have nevertheless been incidentally charged with educational responsibilities, there should be established such a *rapport* between them and the Board of Education as would result in a division of labour and in greater administrative simplicity. If all the schools under the care respectively of the War Office, the Admiralty, the Local Government Board, the Home Office, and the Board of Agriculture were subject to the visitation of H.M. Inspectors, and to the same tests and influences by which public elementary schools are yearly controlled and improved, many advantages would accrue. There would be less waste of power; the schools and teachers would benefit by stimulus and comparison; and the several public departments would be relieved of a duty which they are not in a position to fulfil satisfactorily. Moreover, they would yet retain, as recognized local managers, all their present influence in respect of the non-educational and special interests pertaining to the several establishments. The need of such a simple measure of administrative reform has been strongly urged upon the Government by three Departmental Committees or Commissions—that on the Marine and Dockyard Schools, that on the Poor Law Schools, and that on the Reformatory and Industrial Schools; but at present recommendations to this effect have only been adopted in one case, that of the navy. By an agreement, the annual inspection of the Marine Schools and of Greenwich Naval School has been entrusted by the Lords of the Admiralty to the Board of Education, and the result has proved so satisfactory as to furnish a very valuable precedent for future imitation.

**Voluntary efforts needed.** Notwithstanding the far-reaching effect of recent legislation, especially the establishment of a Board of Education charged with the duty of co-ordinating the varied provision for primary, secondary, and technical instruction, there is still, and will probably long remain, ample room for voluntary effort on the part of societies, and for personal initiative on the part of individual thinkers and teachers. The two great societies which took the lead in promoting elementary education—the British and Foreign School Society, founded in 1808, and the National Society for educating the poor in the principles of the Established Church, founded in 1811—still continue to flourish and to render valuable public service, although the area of their useful action is practically restricted to the vindication of the principles which they represent, the encouragement of voluntary effort, and the training of teachers, a work in which both societies, by means of their Normal Colleges, take a leading and effective part. The Roman Catholic Poor School Committee, and the Wesleyan Connexional Committee, are charged with their respective denominational interests, and co-operate heartily with the central government. The *National Association for the Promotion of Secondary and Technical Education* has given a powerful stimulus to public opinion, and has been of special service in furnishing information to County Councils in relation to the duties which the Local Taxation Act cast upon them. Other Voluntary societies have been formed with a view to give greater solidity and corporate life to the teaching profession itself. The *Head Masters' Conference*, which met for the first time at Uppingham in 1869, at the instance of Mr Thring, has become in the course of years very influential, by holding periodical conferences, and by concentrating for the benefit of the schools and of the public at large the experience and knowledge of headmasters of the public schools of the highest rank. Another society, the *Incorporated Association of Head Masters* (1890), admits to membership a larger body of teachers engaged in endowed or other public secondary schools. It numbers 450 members, and in connexion with recent legislation affecting the work of the Board of Education, the registration of teachers, and the organization of higher grade schools, its representations to the Government and to the public have exercised considerable influence. The *Association of Head Mistresses of Endowed and Proprietary Schools* was organized in 1874, with Miss Buss as its first president, and numbers 180 members. Other societies, such as that of *Head Masters of Private Schools*, of *Higher Grade and Science Schools*, and of *Preparatory Schools* respectively, have since been founded, with successful results. The *College of Preceptors*, a chartered society chiefly composed of private teachers, was incorporated in 1849, and was one of the first professional bodies to institute regular courses of pedagogic lectures, and to award after due examination the titles of Licentiate and Associate to teachers. It has also, by means of its

system of examining pupils, given a valuable stimulus to educational progress, especially in many schools which, while distinctly above the rank of elementary, have not availed themselves of the Oxford and Cambridge local examinations. The conferences and discussions which are held at the college during each session have proved of considerable value, both as a help to the members and other teachers in dealing with professional problems, and also as a means of enlisting the attention and sympathy of the general public in relation to these problems. By far the largest of the professional associations is the *National Union of Teachers.* It was established in 1870, and is composed mainly of teachers engaged in public elementary schools. It has 20 district unions, 430 local associations, and nearly 44,000 members; and it holds in turn at each of the great provincial centres an annual conference, generally attended by 1500 members. It has a considerable revenue, and maintains two orphanages, a system of annuities, and a provident fund. Three of its most active officers became Members of Parliament.

All of these are sectional organizations, concerned mainly with the professional interests of one class of teachers. All of them have tended to promote mutual helpfulness and a sense of corporate life among particular groups of members of the teachers' calling. One only of the professional associations has a broader and more comprehensive design. The *Teachers' Guild*, founded in the year 1885, aims at bringing together teachers of both sexes and of all ranks. It has held from time to time many influential public meetings and discussions on questions of educational principles and policy, and it already numbers 4300 members. It has sought from the first to associate in one strong society teachers of all classes; it has concerned itself rather with those problems and discussions which are common to all enlightened teachers alike than with the narrower professional or pecuniary interests of particular classes of teachers or of schools. The combined effect of all these efforts will probably be to raise the profession in public repute and influence. It would be a misfortune, however, if it tended to create a close profession, or to exclude from the ranks of teachers persons distinguished by originality, enthusiasm, and natural aptitude, though unqualified by formal membership. The *National Home Reading Union*, a society which seeks, by the formation of local centres for reading, and by the suggestion of lists of books, to encourage efforts after self-improvement, exercises a beneficent and increasing influence in many parts of England, especially in places and among persons remote from the chief centres of educational activity. It now numbers 13,500 members. The *Working Men's College*, founded in 1854 by Frederic Denison Maurice, and the *College for Working Women* have proved to be the exemplars of many similar institutions in London and the provinces.

**Competition for the public service.**

In estimating the various agencies by which, in England, educational progress has been influenced, it is impossible to overlook the importance of the opening of various employments in the public service to general competition. The number of persons so engaged has increased as new departments have been created and new functions have been assumed by the central Government. The appointment to these offices once rested largely in the hands of the political heads of the several departments, and entailed considerable responsibility. In 1853 Sir Stafford Northcote and Sir Charles Trevelyan reported on the unsatisfactory results of this system, and recommended the formation of a separate and independent Board to test the fitness of candidates for public employment in certain offices. In 1855 the Civil Service Commission was created, and for a time its duties were limited to the holding of qualifying examinations and to the ascertainment of necessary facts respecting age, health, and character. In 1859 the Civil Service of India was thrown open, mainly at the instance of Lord Derby, the Secretary of State for India, and with the energetic support of Macaulay, whose own experience during his four years of office (1834–1838) as legal member of the Supreme Council of India had led him to take great interest in the question. Since that date the principle of open competition has been applied in succession to many branches of the public service. In 1870 an Order in Council made it applicable to home clerkships generally, as well as to many other offices; and more recently candidates for the colonial, the naval, and the military services have been examined by the Civil Service Commissioners. The following statistics are from the report of the Commission for the year 1899:—In all, 38,739 cases have been dealt with, of which 11,478 were those of candidates nominated singly, 4891 were nominated to compete, and 22,360 were examined for open competition. Of these, 3306 succeeded at an open competition, and 7094 in the restricted competition after nomination. The list of offices thus rendered available includes clerkships in the Foreign and Colonial Offices, the Treasury, and the higher departments of the public service, the Indian Civil Service, commissions in the army and navy, surveyors, dockyard schoolmasters, writers, post and telegraph clerks (male and female), and many minor offices in all the Government departments.

The effects of this great revolution in the administrative work of the State are far-reaching, and cannot even yet be fully estimated. The first and most obvious is that thereby Ministers and members of Parliament are saved from much importunity, and from a personal responsibility which it was very difficult for them to exercise with entire fairness and a sole regard to the public interests. The practical abolition of favouritism and of personal patronage in Great Britain has in itself done much to purify the public service and to satisfy the national sense of justice. As a democratic measure, the invitation to persons of all classes, without distinction of rank or social position, to compete on equal terms for honourable employment, has been generally welcomed and valued. There can be little doubt that an effective stimulus has been given to the efforts of many young people towards self-improvement, by the opening of a career as a reward and an encouragement to intellectual merit alone. There remain, however, some questions to which experience has not yet given a final answer, although the evidence which has been already accumulated is weighty and, on the whole, highly encouraging. They are: (*a*) Is the effect of the system to give to the State a more capable and better qualified body of public servants than would be procurable under other conditions? (*b*) What effect has open competition had on the character of the education in the schools and colleges from which the candidates are drawn? and (*c*) How far has it tended to improve or to lower the national estimate of the true worth of education, and its relation to the active business of life? To the first question the answers are not absolutely unanimous. There will always be some cases in which the system of selection by competitive examination appears to be unsatisfactory. But, *exceptis excipiendis*, the general testimony of experience is emphatically favourable, and leads to the conclusion that on the whole the system does succeed in bringing to the front the best men. The warmest advocates of the system cannot, however, overlook its necessary limitations. There are virtues which do not "pay" in examinations, and there are grave faults of character which cannot be detected by any examination, and yet which are not

incompatible with intellectual success. Manliness, courtesy, promptitude, flexibility of mind, a conscientious sense of duty, and a respect for the feelings and the rights of others are all valuable and indeed indispensable attributes for an efficient public officer either in the civil or the military service. But these are precisely the qualities which no conceivable system of examination can adequately test. We can examine only what is examinable. The qualifications which can be tested by examination are accurate knowledge, general intelligence, ability to think and to express the result of thinking in an orderly, coherent, and logical way. These qualifications are not less valuable than the others, and are at least as likely to coexist with them as to be possessed independently. And on this point the judgment expressed by the Civil Service Commissioners in their thirty-third report is on the whole ratified by subsequent experience and by the general verdict of responsible statesmen and of the public. The Commissioners say :—

"We think it sufficient to refer to the reports of the Royal Commission on Civil Establishments, the report of the Public Service Commission (India), and the statements of the military authorities, which show that the persons selected by means of our examinations are well qualified for the public service. The Royal Commissioners on Civil Establishments, in their second report, paragraph 32, say of the lower division clerks: 'As stated in our former report, paragraph 109, we are of opinion that the young men of this grade who have entered the service since the Order in Council of 1876 are of excellent quality and capacity.' This statement is further confirmed by the fact that out of 3241 men clerks appointed between 1876 and 1888 only 23 have been rejected on probation on the score of inefficiency. A favourable opinion is also expressed of the officers of the higher division in paragraph 109 of the first report. The Public Service Commission (India) reports that 'on more than one occasion inquiries have been made by Government into the working of the competitive system, with the result that it has been generally acknowledged to have procured for the ranks of the Indian Civil Service officers who, as a body, are eminently qualified for the performance of the duties which devolve upon them, and many of whom have earned a reputation for administrative capacity of a high order.' They believe themselves to be justified in the conclusion that, 'apart from questions of detail as to the age of candidates, and the subjects, standards, and conditions of examination, the general results of competition, as applied to the India Civil Service, have been satisfactory, and that the system should accordingly be maintained.' We have reason to believe that the military authorities are equally satisfied with the officers who have entered the army by means of our examinations."

The medical officer who in 1900 examined the selected candidates for the Civil Service of India reported most favourably of their physique. He said: "They presented no indication of physical depreciation or damage to be attributed to the influences of study. For the most part they presented the evidence of vigorous health, and bore the stamp of the University and the public school."

The Civil Service Commissioners provide for several grades of examination, which may roughly be described as falling under one of these five heads :—

(1) *University type :* Indian Civil Service and Class I. of the Home Civil Service.
(2) *First Grade or Public School type :* Army and Navy Examinations, *e.g.*, Sandhurst and Woolwich.
(3) *Second Grade School type :* Second division clerks.
(4) *Elementary School type :* Boy copyists and minor offices.
(5) *Technical and Professional groups :* Various special examinations.

The subjects and the scope of these several examinations are in all cases determined by the Commissioners, after full communication with the heads of the various departments concerned and with the Treasury.

It is important to consider the influence exerted by the competitive system on the aims and work of the places of education from which the ranks of public servants are from time to time recruited. At first there was on the part of teachers and professors a disposition, easily explicable, to object to the setting up by any external body of an independent standard of attainment; and the examinations of the Civil Service Commissioners were for nearly thirty years practically ignored by University authorities and by the masters of the great public schools, notwithstanding the great variety of optional subjects offered to candidates. Hence parents who desired to obtain commissions or public employment for their sons were fain to resort to private tutors, who made it their business to understand thoroughly the conditions of success in examination, and who often achieved great success in passing their candidates. They were sometimes vaguely denounced as "crammers," and their methods as contrivances for enabling young learners to deceive the examiners by the appearance without the reality of knowledge, and by crude and hasty efforts of memory rather than by diligent and solid study. There was no doubt some real danger in this direction, a danger from which the Universities themselves, in preparing undergraduates for Honour examinations, are not wholly free. But the best of the private tutors sought to guard against possible evil of this kind, partly by declining to accept as pupils youths who, owing to deficient preliminary training or to any other cause, had no reasonable prospect of success, and partly by insisting on diligent attention to a serious course of study and discipline, such as would enable candidates to systematize and arrange their knowledge and express it in the best form. Nevertheless it has been more and more strongly felt that the break in the continuity of a youth's studies caused by his premature removal from a public school or a University to a private teacher had often an unfavourable effect both on his moral and his intellectual discipline. Hence it has become evident that the standard of qualification required for entrance into the public service ought to be as nearly as possible assimilated to the standard which is attained in a good school. To a large extent this object has been achieved. On the one hand, all the recent policy of the Commissioners has been in favour of taking the course prescribed in the Universities and public schools, from which the candidates are recruited, as the best practical measure of the qualifications which ought to be required at the competitive examination. And on the other hand, the public schools and University authorities have co-operated with the Commissioners by widening their curriculum, and helping to render the services of special tutors outside the schools to a large extent unnecessary, except in the case of special technical departments. On this point the testimony of Dr Magrath, the Provost of Queen's College, and lately the Vice-Chancellor of the University of Oxford, is significant and valuable. He says :—

"I strongly feel that, as at present conducted, the higher of these examinations directly and efficiently contribute to the maintenance of a considerable element of general culture in the studies of those schools in England which keep their pupils to seventeen or beyond. The excessive and unreasonable desire for the introduction of what are called useful, *i.e.*, professional, subjects into all forms of education, from the highest to the lowest, would, I believe, have much more extensively affected the curricula of these schools if the Civil Service Commissioners had not framed their examinations with a view to securing for the higher class of posts in the service those who have received the best general education. It is a curious example of the funny paradoxical way in which we blunder eventually into the best course, that it was not professional educators, or even members of what might be called our educational hierarchy, who have brought about this result, but persons appointed to secure fair play among those who aimed at administrative posts thrown open on the abolition of patronage and favouritism. It is the fact that these posts have been secured to a large extent by lower middle class men who have had the ability and the good fortune to be able to continue their general studies for a longer period than usual, which has set before the parents of such boys an object of ambition on the boys' behalf, which has stimulated these parents to make often very considerable efforts to secure for their sons such educational

advantages as might enable them to compete with some degree of success for these posts; and this result has reached already down to schools of a much lower educational class than could have been supposed to be affected by it. Its effects have been, I think, wholly beneficial."

To this weighty experience may be added that of Dr Warre, the headmaster of Eton, who says, in reference to competition for the army:—

'The army examination has had a very considerable influence here. It has caused the institution of an army class, the aim of which is to send boys straight from the school to Woolwich and Sandhurst, saving them from having to go to a private tutor for special preparation.

"The institution of the army class has reacted distinctly upon the school and its work. Formerly the boys who chose the army for their profession (mostly vigorous and high-spirited lads) were as a rule the idlest and the most difficult to manage, and consequently maintained a low standard of industry and discipline and of interest in their work. The army class has changed all this, and these lads are now among the hardest working and steadiest in the school.

"This has had its effect upon the rest. The consequence, briefly stated, is that the rank and file throughout the school do better as regards work. The general average of work has, in my opinion, distinctly improved in the last ten years, and among the causes I think that the institution of the army class has no small share, and this is therefore due to the public competition for entrance into Woolwich and Sandhurst."

In another great public school—that of St Paul's in London—the master of the army class points out "that although the aim of the form is mainly admission to Woolwich, and is based upon the syllabus of the Woolwich Entrance Examination, not more than two-thirds of the boys are candidates for the army. Others desire to proceed to Cooper's Hill, the City and Guilds of London Technical Institute, or the navy as engineer-students, or to prepare for such examinations as the Institute of Actuaries, in which mathematics play an important part. In respect of the qualities of character and intellect, the army form may be fairly taken as representative of the school as a whole, and discipline is maintained with the same ease. The intimate association of the two elements, the military and the civil, benefits the whole form, and the boys in this department have always taken a prominent part in the athletics of the school." From many quarters other evidence comes showing that, in the opinion of the teachers, the examinations of the Civil Service Commissioners have been much improved, and that as experience grows there is greater similarity in aim and method between the views and plans of good teachers and the requirements of the Civil Service Commissioners.

**Educational literature.**

The last quarter of the 19th century was characterized by considerable activity and productiveness in the literature of education. Except Ascham's *Scholemaster*, Mulcaster's *Positions*, Milton's *Tractate*, and Locke's *Thoughts*, the England of former generations had contributed little to pedagogic theory. But in recent years contributions to the history, the philosophy, and the practice of education have been very numerous in Great Britain as well as in Germany, France, and the United States. For a general bibliography of the subject the student will do well to consult, in German, W. Rein's *Encyclopädisches Handbuch des Pädagogik*, and K. A. Schmid's *Encyclopädia der gesammten Erziehungs- und Unterrichtswesens;* in French, F. Buisson's *Dictionnaire de pédagogie;* and in English, W. S. Munroe's *Bibliography of Education*, Henry Barnard's *English Pedagogy*, and Sonnenschein's *Cyclopædia of Education.* The history of the growth of ideas and theories on education can best be studied in Professor S. Laurie's *Historical Survey of Pre-Christian Education* and *Life of Comenius*, Oscar Browning's *Educational Theories*, H. T. Mark's *Outlines of the History of Educational Theories*, Compayré's *History of Pedagogy*, Mahaffy's *Old Greek Education*, and Donaldson's, Hailmann's, or Joseph Payne's *History of Education*, J. B. Mullinger's *The Schools of Charles the Great*, J. H. Newman's *Rise and Progress of Universities*, R. H. Quick's *Educational Reformers*, J. M. Leitch's *Practical Educationists*, Sir J. K. Shuttleworth's *Four Periods of Education*, Matthew Arnold's article on "Schools" in Humphry Ward's *Reign of Queen Victoria*, and his *Popular Education in France* and official *Reports to the Education Department*, edited by Lord Sandford, Stanley's *Life of Dr Arnold*, Meiklejohn's *Life of Dr Andrew Bell*, Lupton's *Life of Dean Colet*, three *Lives of Pestalozzi*, by De Guimps, Dr Biber, and Karl von Raumer, John Morley's *Rousseau*, J. P. Richter's *Autobiography*, Hugh Miller's *My Schools and Schoolmasters*, Sir Henry Craik's *The State and Education*, the volumes of *Special Reports* issued by the Board of Education, and the series of *Great Educators* published by Heinemann. From the theoretical or speculative as well as the practical side, other additions to educational literature have been Herbert Spencer's *Education; Intellectual, Moral, and Physical*, Bain's *Education as a Science*, Herbart's *Science of Education*, F. Fröbel's *Education of Man*, Pestalozzi's *Leonard and Gertrude*, J. P. Richter's *Levana*, the Reports of the American *Committee of Fifteen*, *Educational Aims and Methods*, and the *Lectures on Teaching*, delivered before the University of Cambridge by the present writer, M. Bréal's *Quelques mots sur l'instruction publique*, Lloyd Morgan's *Psychology for Teachers*, Edward Thring's *Theory and Practice of Teaching* and *Education and the School*, President Eliot's *Educational Reform*, and Professor N. Murray Butler's *The Meaning of Education*, P. A. Barnett's *Common Sense Applied to Education*, and Bernard Bosanquet's *The Education of the Young* (in the *Republic* of Plato). The official Reports of *Royal Commissions*, notably those of the *Schools Inquiry* of 1867, Lord Cross's Commission on *Primary Education*, 1887, and Mr Bryce's Commission on Secondary Instruction, 1894, deserve special attention, and the Annual Reports of the Department now known as the Board of Education will always be found to give the latest financial and other statistical details respecting the number of teachers and scholars in the elementary and other schools under the supervision of that Department.

**The problems of the future.**

At the beginning of the 20th century the outlook on the future of English education is, though somewhat obscure, full of promise. The latest Act of the Government, constituting a central Board with power to co-ordinate the scattered agencies hitherto concerned with public elementary schools, with science and art, and with technical education, as well as with the administration of the Endowed Schools Acts, has possibilities of usefulness in it which are not yet fully realized. It will, it may be hoped, succeed in giving unity of purpose to the whole educational machinery of England, and will define the several duties of the School Boards, the County Councils, and other local authorities, and their relations to the central Government and to each other. It will provide for the information of parents an annual register of qualified teachers and of approved schools. It will furnish large and equal opportunities to promising learners in all classes of the community to pursue their studies and to cultivate their different powers and aptitudes. It will so far stimulate local authorities as to secure that there is as ample a provision of secondary as already exists for primary schools all over England. It will afford to the public a guarantee of efficiency, by means of a judicious combination of inspection with examination, following in this particular the weighty recommendation

of the Royal Commission of 1895. "Education," says the Report (vol. i. p. 120), "needs organization, but it would be destroyed by uniformity: it is stimulated by inspection, but it would be crushed by a Code. In the public service, where the chief object is administrative efficiency, the individual officer is necessarily subordinate; in education, where a chief object is the discovery of more perfect methods of teaching, the individual teacher must be left comparatively free. Every good teacher is a discoverer, and in order to make discoveries he must have liberty of experiment." It is not by larger grants of public money alone that educational progress can be secured. The subsidies already paid out of the Treasury to elementary schools are very liberal, and the various religious bodies cannot reasonably ask for more pecuniary help than they at present receive, unless they are prepared to give their schools a more national character by accepting representatives of the public as colleagues in the management. But public funds for the erection of good secondary, technical, and commercial schools will, however, be needed, and the source from which these funds will be derived, and the constitution of the authority which is to control their administration, have yet to be determined. Endowments for schools and scholarships need to be made still more efficient; they are inadequate in amount, and too capriciously distributed, to supply all modern needs. The parent who does not desire to avail himself of the public elementary school, and whose sons are not likely to succeed in a competitive examination, has still to complain that advanced education is more costly in England than in any other country, and that institutions with moderate fees such as the *Lycées* of France, or the *Realschulen* or the *Gymnasien* of Germany, are not accessible to him. There is therefore room for some further action on the part of the State. But it is not to legislation exclusively, or even mainly, that we must look for the completion of the edifice of public education. That part of the work of the future "which kings or laws can cause or cure" is comparatively a small part. Parliament must in the last resort receive its mandate from the people, and can do little more than seek to fulfil the national ideals. The motive force which we need must be found in a higher and truer popular conception of a liberal education, and of its relation to the formation of character and to the duties of industrial, civic, and family life. That the acquisition of knowledge, though obviously the prominent business of a school, is not the whole of education, and that knowledge consciously directed to the special professional and industrial needs of life is of far less real value than the knowledge which helps to bring out the best powers of the reflective and accomplished man, are truths which are yet imperfectly recognized. We yet need a more general agreement as to the place which the training of the hand and eye, and the constructive and inventive faculties, should hold in a scheme of intellectual culture. And in an age in which merely ecclesiastical influence over public education is waning, we need to hold fast by all such agencies as exist for the cultivation of the spiritual part of man, his emotions, and his aspirations after goodness, and his love of truth. How to cultivate in schools a genuine yet modest patriotism, and a desire to render service in municipal or public life; how to give to parents a stronger interest in the education of their children, and increased opportunities of co-operating with the teachers; how to enlarge the boundaries of educational science, and to give increased freshness and vitality to the methods of instruction—all these are problems which await solution in the 20th century. They were only partially and imperfectly solved in the 19th. (J. G. F.)

## Education in the United States.

***Beginnings.*** The first white settlers who came to North America were typical representatives of those European peoples who had made more progress in civilization than any other in the world. Those settlers, in particular those from England and from Holland, brought with them the most advanced ideas of the time on the subject of education. The conditions of life in the New World emphasized the need of schools and colleges, and among the earliest public acts of the settlers were provisions to establish them. The steps taken between 1619 and 1622 to provide schools for the colony of Virginia were frustrated by the Indian war which broke out in the latter year, and were never successfully renewed during the colonial period. In New York, where the influence of the Dutch was at first predominant, elementary schools were maintained at the public expense, and were intended for the education of all classes of the population. This policy reflected the very advanced views as to public elementary education which were then held in the Netherlands. The assumption of control in the colony of New York by the English was a distinct check to the development of public elementary education, and little or no further progress was made until after the Revolution. The most systematic educational policy was pursued in the colony of Massachusetts. As early as 1635, five years after it was founded, the town of Boston took action to the end that "our brother Philemon Pormort shall be entreated to become schoolmaster for the teaching and nurturing children with us." The General Court of the colony in 1636 made the first appropriation for what was to become Harvard College, taking its name in honour of the minister, John Harvard, who died in 1638, leaving his library and one-half of his property, having a value of £800, to the new institution. The amount of this appropriation of 1636 (£400) was remarkable in that it was probably equal to the whole colony tax for a year. In 1642 followed a legislative Act which, while saying nothing of schools, gave to the selectmen in every town power to oversee both the education and the employment of children. It is made the duty of the selectmen to see that the children can read and understand the principles of religion and the capital laws of the country, and that they are put to some useful work. Five years later, in 1647, was enacted the law which is not only the real foundation of the Massachusetts school system, but the type of later legislation throughout the United States. This epoch-making Act, the first of its kind in the world, represented the public opinion of a colony of about 20,000 persons, living in thirty towns. It required every town of fifty householders to establish a school, the master of which should be paid either by the parents of the children taught or by public tax, as the majority of the town committee might decide; and it further required every town of one hundred families or householders to set up a grammar school in which pupils might be prepared for the "University," as the new institution at Cambridge was designated. Moreover, a penalty was attached to neglect of this legislative requirement, in the form of a fine to be devoted to the maintenance of the nearest school. Horace Mann said of the Act of 1647: "It is impossible for us adequately to conceive the boldness of the measure, which aimed at universal education through the establishment of free schools. As a fact, it had no precedent in the world's history; and, as a theory, it could have been refuted and silenced by a more formidable array of argument and experience than was ever marshalled against any other institution of human origin. But time has ratified its soundness. Two centuries of successful operation now proclaim it to be as wise as it was courageous, and as beneficent as it was disinterested." The significance

of these Acts of 1642 and 1647 is that they foreshadow the whole American system of education, including elementary schools, secondary schools, and colleges, and that they indicate the principles upon which that system rests. These principles as summarized by George H. Martin in his *Evolution of the Massachusetts Public School System* are the following:—(1) The universal education of youth is essential to the well-being of the State. (2) The obligation to furnish this education rests primarily upon the parent. (3) The State has a right to enforce this obligation. (4) The State may fix a standard which shall determine the kind of education and the minimum amount. (5) Public money raised by general tax may be used to provide such education as the State requires. The tax may be general, though the school attendance is not. (6) Education higher than the rudiments may be supplied by the State. Opportunity must be provided at the public expense for youths who wish to be fitted for college. These principles have now found expression in the public Acts of every State, and upon them education in the United States is founded.

*Development.* Despite the praiseworthy attempts made in New York, New Jersey, and Pennsylvania to develop schools and school systems, very little was accomplished in those colonies which was permanent. The sentiment in the more southern colonies was, as a rule, unfriendly to free schools, and nothing of importance was attempted in that section of the country until the time of Thomas Jefferson. Through religious zeal or philanthropy colleges were founded as far south as Virginia, and no fewer than ten of these institutions were in operation in 1776. Their present names and the dates of their foundation are: Harvard University, Massachusetts (1636); College of William and Mary, Virginia (1693); Yale University, Connecticut (1701); Princeton University, New Jersey (1746); Washington and Lee University, Virginia (1749); University of Pennsylvania, Pennsylvania (1751); Columbia University, New York (1754); Brown University, Rhode Island (1764); Rutgers College, New Jersey (1766); and Dartmouth College, New Hampshire (1770). In the colleges the ecclesiastical spirit was at first almost uniformly dominant. The greater number of their students were preparing for the ministry in some one of the branches of the Protestant Church. These facts caused the grammar schools to take on more and more the character of college-preparatory schools; and when this was brought about they supplied the educational needs of but one portion of the community. As time passed, the interdependence of governmental and ecclesiastical interests began to weaken in the colonies, and there arose among those who represented the new secularizing tendency a distrust of the colleges and their influence. This gave rise to a new and influential type of school, the academy, which took its name from the secondary schools established in England by the dissenting religious bodies during the latter part of the seventeenth century at the suggestion of Milton. These academies were intended to give an education which was thought to be more practical than that offered by the colleges, and they drew their students from the so-called middle classes of society. The older academies were usually endowed institutions, organized under the control of religious organizations or of self-perpetuating boards of trustees. Their programme of studies was less restricted than that of the grammar schools, and they gave new emphasis to the study of the English language and its literature, of mathematics and of the new sciences of nature. For two generations the academies were a most beneficent factor in American education, and they supplied a large number of the better-prepared teachers for work in other schools. These schools were in a sense public in that they were chartered, but they were not directly under public control in their management. Early in the 19th century there arose a well-defined demand for public secondary schools—high schools, as they are popularly known. They were the direct outgrowth of the elementary school system. Boston, Philadelphia, Baltimore, and New York were the first of the large cities to establish schools of this type, and they spread rapidly. These public secondary schools met with opposition, however, springing partly from the friends of the academies, and partly from those who held that governmental agency should be restricted to the field of elementary education. The legal questions raised were settled by a decision of the Supreme Court of Michigan, which contained these words: "Neither in our State policy, in our constitution, nor in our laws do we find the primary school districts restricted in the branches of knowledge which their officers may cause to be taught, or the grade of instruction that may be given, if their voters consent, in regular form, to bear the expense and raise the taxes for the purpose." This decision gave marked impetus to the development of public secondary, or high schools, and they have increased rapidly in number. The academies have relatively declined, and in the Western States are almost unknown.

Meanwhile the elementary school system had grown rapidly. The school district, the smallest civil division, was created in Connecticut in 1701, in Rhode Island about 1750, and in Massachusetts in 1789. From the point of view of efficient, well-supported schools, it has been felt since the time of Horace Mann that the substitution of the small school district for the town as the unit of school administration was a mistake. Yet the school district has exercised a profound influence for good upon the American people. In New York State, for example, there were in 1900 over eleven thousand school districts, and in Illinois over twelve thousand. The districts are small in extent and often sparsely settled. Their government is as democratic as possible. The resident legal voters, often including women, hold a meeting at least once a year. They elect trustees to represent them in the employment of the teacher and the management of the school. They determine whether a new schoolhouse shall be built, whether repairs shall be made, and what sum of money shall be raised for school purposes. In the rural districts this system has often been itself a school in patriotism and in the conduct of public affairs. Recently the tendency is to merge the school districts into the township, in order that larger and better schools may be maintained, and that educational advantages may be distributed more evenly among the people. Most of the Southern states have the county system of school administration. This is because the county, rather than the township, has been the political unit in the South from the beginning. Special laws have been made for the school system in cities, and the form of these laws differs very much. In nearly every city there is a separate board of education, sometimes chosen by the voters, sometimes appointed by the mayor or other official, which board has full control of the schools. The city board of education has as its executive officer a superintendent of schools, who has become a most important factor in American educational administration. He exerts great influence in the selection of teachers, in the choice of text-books, in the arrangement of the programme of studies, and in the determination of questions of policy. Sometimes he is charged by law with the initiative in some or all of these matters. He is usually a trained administrator as well as an experienced teacher. The first superintendent was appointed in 1837 at Buffalo. Providence followed in 1839, New Orleans in 1841, Cleveland in 1844, Baltimore in 1849, Cincinnati in 1850, Boston in 1851, New York, San Francisco, and Jersey City in 1852, Newark and

Brooklyn in 1853, Chicago and St Louis in 1854, and Philadelphia in 1883. In general, it may be said that the progress of public education in the United States is marked by (1) compulsory schools, (2) compulsory licensing of teachers, (3) compulsory school attendance, and (4) compulsory school supervision, and by the increasingly efficient administration of these provisions. The compulsion comes in each case from the State government, which alone, in the American system, has the power to prescribe it and to enforce it. Each one of the 45 States is therefore an independent educational unit, and there is no single, uniform American system of education in any legal sense. In fact, however, the great mass of the American people are in entire agreement as to the principles which should control public education; and the points in which the policies of the several States are in agreement are greater, both in number and in importance, than those in which they differ. An American educational system exists, therefore, in spirit and in substance, though not in form.

***National policy.***

Neither in the Declaration of Independence nor in the Constitution of the United States is there any mention of education. The founders of the nation were by no means indifferent to education, but they shared the common view of their time, which was that the real responsibility for the maintenance of schools and the expense of maintaining them should fall upon the several local communities. The relation of government to education was not then a subject of ordinary consideration or discussion. Later, when this question did arise and the power of taxation was involved, the several States assumed control of education, as it was necessary that they should do. Nevertheless, from the very beginning the national government has aided and supported education, while not controlling it. This policy dates from 13th July 1787, when there was passed the famous "Ordinance for the Government of the Territory of the United States North-West of the River Ohio," meaning the territory north and west of the Ohio river now represented by the states of Ohio, Indiana, Illinois, Michigan, Wisconsin, and the eastern side of Minnesota, embracing more than 265,000 square miles of territory. This Ordinance contains this declaration: "Religion, morality, and knowledge being necessary to good government and the happiness of mankind, schools and the means of education shall for ever be encouraged." The Ordinance of 1787 also reaffirmed the provisions of the so-called Land Ordinance of 1785, by which section No. 16 in every township (a township consists of 36 numbered sections of one square mile each), or one thirty-sixth of the entire North-West Territory, was set aside for the maintenance of public schools within the township. The funds derived from the sale and lease of these original "school lands" form the major portion of the public school endowment of the States formed out of the North-West Territory. The precedent thus established became the policy of the nation. Each State admitted prior to 1848 reserved section No. 16 in every township of public land for common schools. Each State admitted since 1848 (Utah being an exception, and having four sections) has reserved sections No. 16 and No. 36 in every township of public lands, for this purpose. These national grants of land in aid of common schools amount to 67,893,919 acres. In addition, the national government has granted two townships in every State and Territory containing public lands for seminaries or universities. These grants amount to 1,165,520 acres. A third land grant is that made in 1862 for colleges of agriculture and the mechanical arts; this amounts to 9,600,000 acres. The sum total of these three land grants is 78,659,439 acres, to which there must be added various special grants made from time to time to the States and devoted to education. The portion of the public domain so set apart amounts in all to 86,138,473 acres, or 134,591 English square miles. This is an area greater than those of the six New England States, New York, New Jersey, Maryland, and Delaware added together. It is a portion of the earth's surface as great as the kingdom of Prussia, about seven-tenths as great as France, and considerably greater than the combined areas of Great Britain (including the Channel Islands) and the kingdom of Holland. Besides the enormous grants of land in aid of education, the national government has maintained since 1802 a military academy at West Point, New York, for the training of officers for the army, and since 1845 a naval academy at Annapolis, Maryland, for the training of officers for the navy. It has also taken charge of the education of the children of uncivilized Indians, and of all children in Alaska. It has voted, by Act of 1887, a perpetual endowment of $15,000 a year for each agricultural experiment station connected with a State agricultural college, and, by Act of 1890, an additional endowment of $25,000 a year for each of the agricultural colleges themselves. The aggregate value of land and money given by the national government for education in the several States and Territories is about $300,000,000.

***Bureau of education.***

In 1867 the Congress established a bureau of education, presided over by a Commissioner who is under the jurisdiction of the Secretary of the Interior, the purpose of which is declared to be to collect "such statistics and facts as shall show the condition and progress of education in the several States and Territories, and of diffusing such information respecting the organization and management of school systems and methods of teaching as shall aid the people of the United States in the establishment and maintenance of efficient school systems, and otherwise promote the cause of education throughout the country." The bureau has therefore no direct power over the educational policy of the several States. It has, however, exercised a potent influence for good in its advisory capacity. Up to 1900 this bureau had published 360 separate volumes and pamphlets, including 31 annual reports, covering from 800 to 2300 pages each. These are standard works of reference, and are distributed gratuitously in large numbers to libraries, school officials and other persons interested, and to foreign Governments. The several commissioners of education have been: Henry Barnard of Connecticut, 1867–1870; John Eaton of Ohio, 1870–1886; Nathaniel H. R. Dawson of Alabama, 1886–1889; William T. Harris of Massachusetts, 1889 to date.

***State governments and education.***

In the United States the sovereign powers are not all lodged in one place. Such of those powers as are not granted by the Constitution to the national government are reserved to the States respectively, or to the people. The power to levy taxes for the support of public education has been almost universally held to be one of the powers so reserved. The inhabitants of the several local communities, however indisposed they may have been to relinquish absolute control of their own schools, have been compelled to yield to the authority of the State government whenever it has been asserted, for except under such authority no civil division—county, city, township, or school district—possesses the power to levy taxes for school purposes. Moreover, since the exercise of State authority has uniformly improved the quality of the schools, it has usually been welcomed, not resisted. In general, it may be said that the State has used its authority to prescribe a minimum of efficiency which schools and teachers must reach, and it enforces this minimum through inspection

and the withholding of its proper share of the State school fund from any locality where schools or teachers are permitted to fall below the required standard. In extreme cases the State authorities have interfered directly to prevent the evil results of local inefficiency or contumacy. In addition, the States, almost without exception, maintain at their own expense schools for the training of teachers, known as normal schools. Many of the States also offer inducements to the cities, towns, and districts to exceed the prescribed minimum of efficiency. Through the steady exercise of State supervision the school buildings have improved, the standard for entrance upon the work of teaching has been raised, the programme of studies has been made more effective and more uniform, and the length of the school term has increased. The Constitution of every State now contains some provision as to public education. Each State has an executive officer charged with the enforcement of the State school laws. Sometimes, as in New York, this official has plenary powers; sometimes, as in Massachusetts and Ohio, he is little more than an adviser. In twenty-nine States this official is known as the superintendent of public instruction; in Massachusetts and Connecticut he is called secretary of the State board of education; other titles used are commissioner of public schools, superintendent of common schools, and superintendent of public schools. The schools are administered, on behalf of the taxpayers, by an elected board of school trustees in rural school districts, and by an elected (though sometimes appointed) board of education or school committee in cities and towns. In 836 cities and towns there is a local superintendent of schools, who directs and supervises the educational work and acts as the executive officer of the board of education. The schools in the rural districts are under the direct supervision of a county superintendent of schools or similar official, who is often chosen by the people, but who sometimes is named by the State authorities. The county and city superintendents are often charged with the duty of holding examinations for entrance upon the work of teaching, and of issuing licences to those persons who pass the examinations. This system works best where it is carefully regulated by State law. Thirty States, one Territory, and the District of Columbia have enacted compulsory education laws, but the enforcement of them is usually very lax. In fifteen States and Territories there are no compulsory education laws, although there are in existence there fully organized school systems free to all children. The usual age during which school attendance is required is from 8 to 14. Provision is made in Maine, New Hampshire, Massachusetts, Rhode Island, Connecticut, New York, New Jersey, Pennsylvania, Indiana, Minnesota, and Michigan, for sending habitual truants to some special institution. Laws forbidding the employment of children under a specified minimum age in any mercantile or manufacturing establishment are in force in twelve States, and are usually administered in connexion with the compulsory education laws. The universal establishment of public secondary schools (high schools), and the existence of State universities in all of the States south and west of Pennsylvania, has brought into existence a system of State education which reaches from the kindergarten and the elementary school to the graduate instruction offered at State colleges and universities. This system includes (1) about 1500 free public kindergartens scattered over fifteen States; (2) free public elementary schools within reach of almost every home in the land; (3) free public secondary schools (high schools) in every considerable city or town and in not a few rural communities; (4) free land grant colleges, supported in large part by the proceeds of the nation's endowment of public lands, paying particular attention to agriculture and the mechanical arts, in all the States; (5) State universities, free or substantially so, in all the States south and west of Pennsylvania; (6) free public normal schools, for the professional training of teachers, in every State except Nevada and Wyoming, and in every Territory except Indian Territory; (7) free schools for the education of defectives in nearly all the States; and (8) the national academies at West Point and Annapolis for the professional training of military and naval officers respectively.

*Kindergartens.*

Miss Susan E. Blow, herself the leading exponent of kindergarten principles in the United States, has pointed out that the history of the kindergarten movement reveals four distinct stages in its development: the pioneer stage, having Boston as its centre; the philanthropic stage, which began in the village of Florence, Mass., and reached its climax at San Francisco, California; the national or strictly educational stage, which began at St Louis; and the so-called maternal stage, which from Chicago as a centre is spreading over the entire country. During the first stage public attention was directed to a few of the most important aspects of Froebel's teaching. During the second stage the kindergarten was valued largely as a reformatory and redemptive influence. During the third stage the fundamental principles underlying kindergarten training were scientifically studied and expounded, and the kindergarten became part of the public school system of the country. The fourth stage, which, like the third, is fortunately still in existence, aims at making the kindergarten a link between the school and the home, and so to use it to strengthen the foundations and elevate the ideals of family life. In 1898 there were 4363 kindergartens in the United States (1365 of which were public), employing 9937 teachers (2532 in the public kindergartens) and enrolling 189,604 children (95,867 in the public kindergartens). Of the 164 public normal schools, 36 make provision for training kindergarten teachers. The scientific and literary activity of some of the private kindergarten training classes is very great, and they exert a beneficial and stimulating effect on teaching in the elementary schools. It is generally admitted that from the point of view of the children, of the teachers, of the schools, and of the community at large, the kindergarten has been and is an inspiration of incalculable value.

*Elementary schools.*

The elementary school course is from six to nine years in length, the ordinary period being eight years. The pupils enter at about six years of age. In the cities the elementary schools are usually in session for five hours daily, except Saturday and Sunday, beginning at 9 a.m. There is an intermission, usually of an hour, at midday, and short recesses during the sessions. In the small rural schools the pupils are usually ungraded, and are taught singly or in varying groups. In the cities and towns there is a careful gradation of pupils, and promotions from grade to grade are made at intervals of a year or of a half-year. The best schools have the most elastic system of gradation and the most frequent promotions. In a number of States there are laws authorizing the conveyance of children to school at the public expense, when the schoolhouse is unduly distant from the homes of a portion of the school population. Co-education of the sexes in the elementary school is the salutary and almost uniform practice in the United States. Fewer than 6 per cent. of the cities offer exceptions to this rule, and in most of these the separation of boys and girls has arisen from the position or original arrangement of the school buildings, and is likely to be discontinued under more favourable conditions. The programme of studies in the elementary school includes English (reading, writing, spelling, grammar, composition), arithmetic (sometimes elementary algebra

also, or plane geometry in the upper grades), geography, history of the United States, and elementary natural science, including human physiology and hygiene. Physical training, vocal music, drawing, and manual training are often taught. Sometimes a foreign language (Latin, German, or French) and the study of general history are begun. Formal instruction in manners and morals is not often found, but the discipline of the school offers the best possible training in the habits of truthfulness, honesty, obedience, regularity, punctuality, and conformity to order. Religious teaching is not permitted, although the exercises of the day are often opened with reading from the Bible, the repetition of the Lord's Prayer, and the singing of a hymn. Corporal punishment is not infrequent, but is forbidden by law in New Jersey, and in many States may be used only under restrictions. Text-books are used as the basis of the instruction given, and the pupils "recite" in class to the teacher, who, by use of illustration and comment, makes clear the subject-matter of the prescribed lesson. The purpose of the recitation method is to make the work of each pupil help that of his companion. Skilfully used, it is the most effectual instrument yet devised for elementary school instruction. In 1897–98 there were 14,589,036 pupils enrolled in the public elementary schools. The average length of the school term was 143·1 days. There were about 380,000 teachers engaged in the elementary schools. About 1,250,000 pupils were at the same time receiving elementary instruction in private or parochial schools.

***Secondary schools.***

The secondary school course is normally four years in length. The principal subjects studied are Latin, Greek, French, German, algebra, geometry, physics, chemistry, physical geography, physiology, rhetoric, English literature, civics, and history. Although but 11·36 per cent. of the students in public high schools, and 25·36 per cent. of those in private secondary schools, are preparing for a college or scientific school, yet the conditions prescribed by the colleges for admission to their courses affect powerfully both the secondary school programme and the methods of teaching. Of late years no educational topic has been more widely discussed than that as to the proper relations of secondary schools and colleges. As a result, special examinations for admission to college are either greatly simplified or entirely abolished, and the secondary studies are much more substantial and better taught than formerly. An increasing proportion of secondary school teachers are college graduates. In 1897–98 there were 5315 public secondary schools and 1990 private secondary schools, or 7305 in all. In these schools 27,298 teachers were employed, 14,681 of them being women. The secondary school students numbered 554,825, of whom 449,600 were in public high schools. The boys numbered 241,359 and the girls 313,466. The most extraordinary characteristic of secondary education in recent years is the rapid increase in the number of students taking Latin as a school subject. In nine years the number of such students has increased from 100,144 (33·62 per cent. of the total) to 274,293 (49·44 per cent.). Meanwhile the proportion of those studying physics and chemistry has fallen off slightly. The rate of increase in the number of pupils who study Latin is fully twice as great as the rate of increase in the number of secondary school students. Between 1890 and 1896, while the number of students in private secondary schools increased 12 per cent., the number of students in public secondary schools increased 87 per cent. Since 1894 the number of students in private secondary schools has steadily declined. In 1897–98 there were 34 public high schools for boys only, 29 for girls only, and the remainder (5252) were co-educational. In the same year there were 351 private secondary schools for boys only, 537 for girls only, and 1212 which were co-educational.

***The colleges.***

The American college, although it is the outgrowth of the English colleges of Oxford and of Cambridge, has developed into an institution which has no counterpart in Europe. The college course of study, at first three years in length, was soon extended to four years, and the classes are uniformly known as the freshman, the sophomore, the junior, and the senior. Whether or not, in view of changed educational and social conditions, a college course of four years is not too long is a question now under serious discussion. The traditional degree which crowns the college course is that of Bachelor of Arts (A.B.). The studies ordinarily insisted on in the case of candidates for this degree are Latin, Greek, mathematics, English, philosophy, political economy, history, at least one modern European language (French or German), and at least one natural science. The degrees of Bachelor of Science (B.S.), Bachelor of Philosophy (Ph.B.), and Bachelor of Letters (B.L.) are often conferred by colleges upon students who have pursued systematic courses of study which do not include Greek or the amount of Latin required for the degree of Bachelor of Arts. The best colleges give instruction which is similar in character to that given in Germany in the three upper classes of the gymnasium and in the introductory courses at the universities, in France in the two upper classes of the lycée and in the first two years of university study, and in England in the upper form of the public schools and during the years of undergraduate residence at Oxford and Cambridge. Since 1870 the colleges have developed enormously. Their resources have multiplied, the number of their students has increased by leaps and bounds, the programme of studies has broadened and deepened, the standards have been raised, and the efficiency of the instruction has greatly increased. Rigidly prescribed courses of study have given way to elective courses, and a knowledge of Greek is no longer required for the degree of A.B. at such influential colleges as Harvard, Columbia, Cornell, and Williams. A strong effort is being made to have the leading colleges give but one degree, that of Bachelor of Arts, and to confer that upon those who complete any substantial course of college studies. A marked change has taken place in the attitude of the college authorities toward the students. A generation ago the college president was a paterfamilias. He knew each student and came into direct personal contact with him. The president and the faculty had supervision not only of the studies of the students, but of their moral and religious life as well. The older type of college professor was not always a great scholar, but he was a student of human nature, with keen intuitions and shrewd insight. The new type is more scholarly in some special direction, often regards teaching as a check upon opportunities for investigation, and disdains troubling himself with a student's personal concerns or intellectual and moral difficulties. The change has not been altogether for the better, and a desirable reaction is now under way. Each college, however small or ill-equipped, exercises a helpful local influence. Ninety per cent. of all college students attend an institution not more than one hundred miles from their own homes. Few colleges have a national constituency, and even in these cases an overwhelming preponderance of the students come from the immediate neighbourhood. This explains, in a measure, the powerful influence which the college has exercised in the life of the nation. While hardly more than one in a hundred of the white male youth of the country has had a college education, yet the college graduates have furnished one-half of all the Presidents of

the United States, most of the justices of the Supreme Court, about one-half of the Cabinet officers and United States senators, and nearly one-third of the House of Representatives. Before the Revolution eleven colleges were founded. From 1776 to 1800, twelve more were added; from 1800 to 1830, thirty-three; from 1830 to 1865, one hundred and eighty; from 1865 to 1898, two hundred and thirty-six. The present total is 472. Their standards, efficiency, and equipment are very diverse, many of the so-called colleges being less effective than some of the better organized secondary schools. Except in New York and Pennsylvania, there is no statutory restriction upon the use of the name college. This is an abuse which is beginning to attract public attention. The number of undergraduate collegiate and technical school students has increased from 573 to each million of inhabitants in 1872, to 1193 in 1898. In 1897 the whole number of professedly collegiate students enrolled in colleges for men, for women, and for both sexes was 84,955, of whom 52,439 were men. There was, therefore, one college student to each 831 of population. There are 114 colleges, exclusive of those for women, enrolling 31,941 students, and as a rule possessing the largest endowments, which are under no ecclesiastical control. Fifty-nine colleges, enrolling 5954 students, are Roman Catholic. Two hundred and eighty-four, enrolling 29,104 students, are under the control of some one of the Protestant denominations.

*The universities.*

In the United States the title "university" is used indiscriminately of institutions which are in reality universities, of institutions which are colleges, and of institutions which are so ill-equipped as not to take rank with good secondary schools. Only time and a greatly increased capacity to distinguish the various types of higher schools will remedy this error. Putting aside tentative and unsuccessful attempts to develop genuine university instruction much earlier, it may safely be said that the opening of the Johns Hopkins University at Baltimore in 1876 began the present movement to organize carefully advanced study and research, requiring a college education of those who wish to enter upon it. This is university instruction properly so-called, and though found elsewhere, it is given chiefly at fourteen institutions: California University, Catholic University of America, Chicago University, Clark University, Columbia University, Cornell University, Harvard University, Johns Hopkins University, Michigan University, Pennsylvania University, Princeton University, Stanford University, Wisconsin University, and Yale University. All of these institutions, except the Catholic University and Clark University, are also colleges. The combination of collegiate and university instruction under one corporation and one executive administration is distinctive of higher education in the United States, and its chief source of strength. The crowning honour of the university student is the degree of Ph.D., although that of A.M.—obtainable in less time and much easier conditions—is also sought. The minimum period of study accepted for the degree of Ph.D. is two years after obtaining the bachelor's degree; but in practice, three, and even four, years of study are found necessary. In addition to carrying on an investigation in the field of his main subject of study, the candidate for the degree of Ph.D. is usually required to pass examinations on one or two subordinate subjects, to possess a reading knowledge of French and German (often of Latin as well), and to submit—usually in printed form—the dissertation which embodies the results of his researches. The methods of instruction in the universities are the lecture, discussion, and work in laboratory or seminary—the latter transplanted from the German universities. The degree of Master of Arts is conferred upon students who, after one year of university residence and study, pass certain prescribed examinations. This degree, like those of D.D., S.T.D., and LL.D., is often conferred by colleges and universities as a purely honorary distinction. The degree of Ph.D. is not so conferred any longer by the best universities. Not a few of the universities maintain schools of law and medicine. Harvard and Yale universities maintain schools of theology as well. The learned publications issued by the universities, or under the direction of university professors, are of great importance, and constitute an imposing body of scientific literature. The national and State governments make increasing use of university officials for public service requiring special training or expert knowledge. In 1871–72 there were only 198 resident graduate (or university) students in the United States. In 1887 this number had risen to 1237, and in 1897 to 4392. These figures are exclusive of professional students, and include only those who are studying in what would be called, in Germany, the philosophical faculty. (See also UNIVERSITIES.) Most extensive provision is made for professional, technical, and special education of all kinds, and for the care and training of the dependent and defective classes, as well as for the education of the Indian and—in the Southern states—of the negro.

The most complete exposition of education as it now exists will be found in Butler, *Education in the United States*, Albany, N.Y., 1900, a series of nineteen monographs which, taken together, cover the whole educational activity of the United States, prepared for the Government educational exhibit at the Paris Exposition of 1900. The official Reports, issued annually, of the Commissioner of Education, at Washington, contain the latest and most authoritative educational statistics of every sort. They also include treatises on special topics, and are indispensable works of reference. The only historical sketch is Boone's *History of Education in the United States*, New York, 1889. Martin, *Evolution of the Massachusetts School System*, New York, 1894, is accurate and valuable. Contemporary discussions of educational topics of interest are provided from year to year in the published *Proceedings* of the National Educational Association, a voluntary organization of teachers of every grade. (N. M. B.)

**Edward VII.** (ALBERT EDWARD), King of Great Britain and Ireland, and of the British Dominions beyond the Seas, Emperor of India, (1841– ——), the eldest son and second child of Queen Victoria and of Albert, Prince Consort, was born at Buckingham Palace on 9th November 1841. He was created prince of Wales and earl of Chester on 4th December following, and was baptized by the archbishop of Canterbury on 25th January 1842. In his childhood he was carefully educated, under the immediate supervision of the Queen, by the Dowager Lady Lyttelton, governess of the royal children; and in his boyhood successively by the Rev. Henry Mildred Birch, formerly an assistant master at Eton, and by Mr F. W. Gibbs, assisted by the Rev. C. F. Tarver and Mr Herbert W. Fisher. He afterwards resided successively at Edinburgh, studying chemistry in its industrial applications under Professor (afterwards Lord) Playfair at the University; at Christ Church college, Oxford; and at the University of Cambridge, where he was a student at Trinity under Dr Whewell. In November 1858 he was made a Knight of the Garter, and received a commission as colonel in the army, ascending in due time to the rank of field-marshal. In 1859 he travelled in Italy and Spain, returning to pursue his studies at the universities, and availed himself of the long vacation of 1860 to pay a visit, under the incognito of "Lord Renfrew," to the United States, where he was received with cordiality, and to Canada, which welcomed him with enthusiasm. The duke of Newcastle, secretary of state for the colonies, acted as his guide and

H.M. King Edward VII.

mentor upon this occasion. Upon the completion of his Cambridge course in June 1861 he joined the camp at the Curragh, where he acquainted himself with the details of military duty. While thus engaged he was, in common with the entire nation, overwhelmed by the unexpected death of his father, 13th December 1861, after a very brief illness. For long the prince remained in absolute seclusion, but in 1862 fulfilled a wish of the deceased Prince Consort by undertaking a tour in the Holy Land under the guidance of Arthur Penrhyn Stanley, afterwards dean of Westminster, who had already travelled in the East and written *Sinai and Palestine*. The travellers departed in February and returned in June. Stanley's *Sermons preached in the East* was among the fruits of their expedition. Early in 1863 the prince was sworn of the Privy Council, and took his seat in the House of Lords as duke of Cornwall. About the same time the estate of Sandringham, in Norfolk, was purchased for him out of the savings of his minority. His town residence was fixed at Marlborough House. His impending marriage to the Princess Alexandra, daughter of Christian IX., king of Denmark (born 1st December 1844), had already been announced, and took place on 10th March in St George's Chapel, Windsor. From her first appearance on British soil the princess captivated the heart of the nation, and Tennyson uttered the public sentiment when he sang, in his ode as poet-laureate, "We are all of us Danes in our welcome of thee." Parliament granted the prince an income of £40,000 a year, exclusive of the revenues of the duchy of Cornwall, and he relinquished his right of succession to the duchy of Saxe-Coburg-Gotha. Prince Albert Victor, afterwards duke of Clarence, was the first offspring of the marriage, being born on 17th January 1864. The births followed of Prince George Frederick Ernest Albert, duke of York, born 3rd June 1865; Princess Louise Victoria Alexandra Dagmar, by marriage duchess of Fife, born 20th February 1867; Princess Victoria Alexandra Olga Mary, born 6th July 1868; and Princess Maud Charlotte Mary Victoria, born 26th November 1869, married to Prince Charles, second son of the Crown Prince of Denmark. From the time of their marriage the prince and princess were more conspicuously before the country than had ever before been the case with any princely pair of the same position. The deep affliction of the widowed sovereign, and the burden of public care which she was now compelled to undertake, unrelieved by the participation of her mainstay and chief adviser, incapacitated her for the performance of most of the social functions of Royalty. The prince and princess of Wales stepped forward to fill her place, and by their tact and the affability of their bearing, and their diligence and punctuality in satisfying every public claim, frequently at great inconvenience to themselves, contributed not a little to that general popularity of the British monarchy among all classes which has proved so important a factor in national politics. The prince's readiness to promote every worthy cause was most marked; no one was a more constant attendant at the meetings and gatherings for objects of public utility in which his position as a prince of the blood royal would permit him to take part, and his speeches were always most effective from their excellent sense and clear enunciation. The most important external event of these years was a tour to Egypt, undertaken in 1869 in company with the duke of Sutherland, Sir Samuel Baker, and others, an account of which was published by Mrs William Grey. The prince also visited Ireland more than once, and opened the International Exhibition of 1871.

On 23rd November 1871 it was announced that the prince would be prevented from paying a visit which had been arranged to the Maharajah Dhuleep Singh by a feverish attack. It soon appeared that the malady was typhoid, contracted, as was supposed, on a visit to Scarborough. The case became so serious that on 29th November the Queen and Princess Alice hurried to Sandringham, where the prince had repaired on feeling the first symptoms of illness. On 1st December there was a slight rally, but on 8th December so serious a relapse occurred that all the royal family came to Sandringham, and for some days the prince's life was despaired of. Under the skilful treatment of Sir William Jenner, Sir William Gull, and Sir James Paget, however, the crisis was surmounted by 16th December, and by Christmas Day the danger was regarded as virtually over. On 27th February 1872 a public thanksgiving was held at St Paul's, amid the most imposing and most affecting demonstrations of public joy and gratitude throughout the empire. The importance attaching to the life of the heir to the Throne was emphasized by the consciousness of his danger and his escape. A republican agitation, indeed, which had seemed to be gathering strength throughout the year in connexion with labour disputes, collapsed entirely, and has never been revived.

In January 1874 the prince of Wales attended the marriage at St Petersburg of his brother, the duke of Edinburgh, with the Grand Duchess Marie of Russia. In the same year he paid a historic visit to Birmingham, where Mr Joseph Chamberlain, not yet a member of Parliament, received him officially as mayor. In March 1875 it was officially announced that he would make a visit to India, carrying out an idea originally conceived by the first Indian viceroy, Earl Canning. He was supposed to travel as heir-apparent, not as representative of the Queen; but the characters could not be kept apart, and in fact the prince's visit was a political event of great importance. Leaving England on 11th October, he was received at Bombay by the viceroy, Lord Northbrook. Here he met a very large number of Indian feudatory princes, whose acquaintance he subsequently improved by visiting at their courts during the seventeen weeks which he spent in the country. During these four months the prince travelled nearly 8000 miles by land and 2500 miles by sea, became acquainted with more rajahs than had all the viceroys who had reigned over India, and saw more of the country than any living Englishman. The rajahs were enchanted by his tact and urbanity. The visit, moreover, led up, as was probably intended, to the Queen's assumption of the title of empress of India in the following year.

The prince's life after this date was full of conspicuous public appearances. In 1885 he visited Ireland at a time of much political excitement, and was received enthusiastically in many quarters and without symptoms of ill-will in any. In 1886 he filled the presidency of the Indian and Colonial Exhibition, opened the Mersey Tunnel, and laid the first stone of the Tower Bridge. In 1887 a large share of the arrangements for the Queen's Jubilee devolved upon him. On 27th July 1889 his eldest daughter, Princess Louise, was married to the duke of Fife. In the autumn he paid a semi-incognito visit to Paris, where he has always been highly popular, viewed the Exhibition, and ascended the Eiffel Tower. In 1890 he opened the Forth Bridge. On 14th January 1892, however, a heavy blow fell upon him and his house by the death of his eldest son, Prince Albert Victor, duke of Clarence and Avondale, after only five days' illness. The young prince, who with his brother had made the tour of the world in H.M.S. *Bacchante*, and after a short career at Oxford and Cambridge was just settling down to play his part in public life, had recently become engaged to Princess Victoria Mary of Teck (born 26th May 1867), and the popularity of the

heir to the Crown had been increased by the expression of his satisfaction at his son's union to an Englishwoman. On 6th July 1893 the broken thread was reunited by the marriage of the princess (popularly known as Princess May) to the brother of the deceased prince, George Frederick, duke of York.

The year 1894 was a busy one for the prince of Wales, who became a member of the Royal Commission on the Housing of the Poor, opened the Tower Bridge, attended the Welsh Eisteddfod and was duly initiated, and paid two visits to Russia—one on the marriage of the Grand Duchess Xenia, the other on the death of the Tsar, his brother-in-law. In 1896 he became first Chancellor of the University of Wales, and his first act after his installation at Aberystwith was to confer an honorary degree upon the princess. He had already been for some years a trustee of the British Museum, and participated actively in its administration. On 22nd July 1896 the prince's third daughter, Princess Maud, was married to Prince Charles of Denmark. The arrangements for the Queen's Jubilee of 1897 depended upon the prince even more than those of the corresponding celebration in 1887: he rode on the Queen's right at the great procession to St Paul's, and as an Admiral of the Fleet presided at the naval review at Spithead, a spectacle unparalleled in the history of the world. In July 1898 the prince had the misfortune to fracture his knee-cap while on a visit to Baron Ferdinand de Rothschild, but completely recovered from the effects of the accident. In December 1899, while passing through Brussels on his way to St Petersburg, he was fired at by a miserable lad named Sipido, crazed by reading anarchist literature. Fortunately, no injury was done.

It was the especial distinction of Albert Edward, prince of Wales, to have been an ornament and support of the throne before he was called upon to fill it himself. This cannot be said of any of his predecessors except Edward the Black Prince. Most princes of Wales have either died or attained the regal dignity too early to leave any conspicuous mark in history as princes. Since the days of the Black Prince only two have enjoyed a popularity comparable to Prince Albert Edward's—Henry of Monmouth and Henry, the son of James I. The glories of Henry V. have cast a veil over the irregularities of Prince Hal; and the popularity of the Stuart Prince Henry arose in great measure from his suppressed antagonism to his father, and the expectation that he would reverse the latter's policy. The other two princes of Wales who have filled a conspicuous place in the public eye, Prince Frederick and George IV., were neither dutiful nor popular. It was reserved for the son of Queen Victoria to show what strength an heir-apparent exemplary in the discharge of the duties of his station can bring to a monarchy, and how important a place, even with the most scrupulous abstinence from party politics, he can fill in the life of a self-governing nation. He was a keen patron of the theatre, and made it his business to know and remember all the distinguished men of the time in arts and letters. His thoroughly British taste for sport was as pronounced as his inclination for most of the contemporary amusements of Society. The "Tranby Croft Case" (1890), in which Sir William Gordon Cumming brought an unsuccessful libel action for having been accused of cheating at a game of baccarat, caused some comment in connexion with the Prince's appearance in the witness-box on behalf of the defendants. But it did him no disservice with the people to have twice won the Derby with his horses Persimmon (1896) and Diamond Jubilee (1900), and his interest in yacht-racing was conspicuously shown at all the important fixtures, his yacht *Britannia* being one of the best of her day. In other respects his activity in the life of the nation and his wide interests may be illustrated by his establishment (1897) of the "Prince of Wales's Hospital Fund," his devotion to the cause of Masonry (he was first elected Grand Master of the Freemasons of England in 1874), and his position as a Bencher of the Middle Temple, where he also became (1887) Treasurer. It was on the occasion of his first appearance at "Grand Night," that the students were for the first time allowed to follow the Prince's example and to smoke in Hall; and this was only one instance of the influence in this respect which the Prince's taste for tobacco had on English society.

On the death of Queen Victoria on 22nd January 1901, the question what title the new king would assume was speedily set at rest by the popular announcement that he would be called Edward the Seventh. The new reign began auspiciously by the holding of a Privy Council at St. James's Palace, at which the King announced his intention to follow in his predecessor's footsteps and to govern as a constitutional sovereign, and received the oaths of allegiance. On 14th February the King and Queen opened Parliament in state. Shortly afterwards it was announced that the visit of the duke and duchess of York to Australia, in order to inaugurate the new Commonwealth, which had been sanctioned by Queen Victoria, would be proceeded with; and on 16th March they set out on board the *Ophir* with a brilliant suite. The tour lasted till 1st November, the duke and duchess having visited Australia, New Zealand, the Cape, and Canada; and on their return the King, on 9th November, created the duke prince of Wales and earl of Chester. In the meanwhile Parliament had settled the new Civil List (*q.v.*) at £470,000 a year. On 22nd May the King had a narrow escape in Southampton Water, on board Sir T. Lipton's yacht *Shamrock II.* (which was to compete for the America Cup). The yacht had her masts, spars, and entire spread of canvas carried away in a squall; but the King suffered no injury. The question of enlarging the Royal title to include specific mention of the colonial empire had been discussed during the year, and on 30th July Parliament passed a Bill to enable the King to style himself "Edward VII., by the grace of God of the United Kingdom of Great Britain and Ireland, and of all the British Dominions beyond the Seas, King, Defender of the Faith, Emperor of India." The Coronation was fixed for 26th June 1902. Two days earlier, however, the King was announced to be suffering from perityphlitis, and on 24th June an operation was performed by Sir Frederick Treves. The Coronation was consequently postponed. On 27th June the King was pronounced "out of immediate danger," and up to 1st July, when this volume was printed, he was stated to be progressing favourably.

The grandchildren of King Edward VII. are—children of the prince and princess of Wales—(1) Prince Edward Albert Christian George Andrew Patrick David, born 23rd June 1894; (2) Prince Albert Frederick Arthur George, born 14th December 1895; (3) Princess Victoria Alexandra Alice Mary, born 25th April 1897; (4) Prince Henry William Frederick Albert, born 15th March 1899. Children of the duke and duchess of Fife—(1) Lady Alexandra Victoria Alberta Edwina Louise Duff, born 17th May 1891; (2) Lady Maud Alexandra Victoria Georgina Bertha Duff, born 3rd April 1893.

**Edwardsville,** capital of Madison county, Illinois, U.S.A., on Cahokia creek, at an altitude of 554 feet. It has three railways, the Wabash, the Toledo, St Louis, and Kansas City, and the Chicago, Peoria, and St Louis. Population (1880), 2887; (1890), 3561; (1900), 4157

**Edwardsville,** a borough of Lucerne county, Pa., U.S.A., in the anthracite coal region, on the north branch of the Susquehanna river. The official name of the post office is Edwardsdale. Population (1900), 5165.

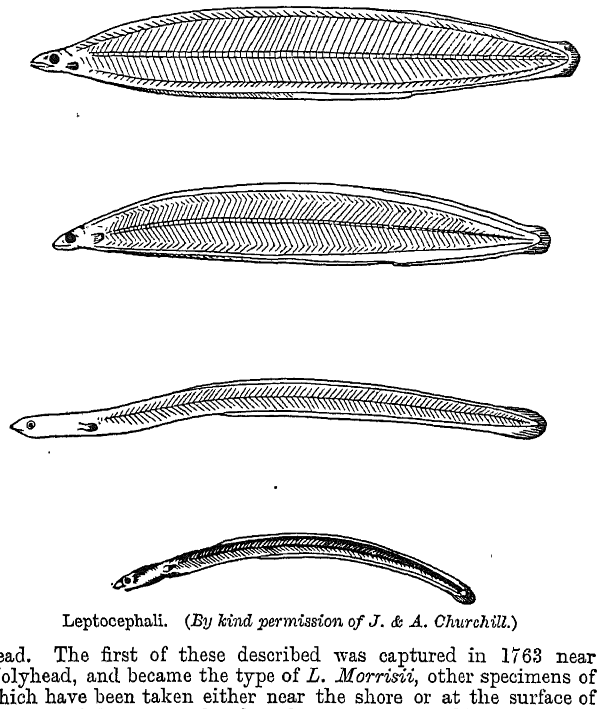
**Eel.**—The common fresh-water eel belongs to a group of soft-rayed fishes distinguished by the presence of an opening to the air-bladder and the absence of the pelvic fins. With its nearest relatives it forms the family Murænidæ, all of which are of elongated cylindrical form. The special peculiarities of the eel are the rudimentary scales buried in the skin, the well-developed pectoral fins, the rounded tail fin continuous with the dorsal and ventral fins. Only one other species of the family occurs in British waters, namely, the conger, which is usually much larger, and lives in the sea. In the conger the eyes are larger than in the eel, and the upper jaw overlaps the lower, whereas in the eel the lower jaw projects beyond the upper. Both species are voracious and predatory, and feed on almost any animal food they can obtain, living or dead. The conger is especially fond of squid or other Cephalopods, while the eel is partial to carrion. The common eel occurs in all the rivers and fresh waters of Europe, except those draining towards the Arctic Ocean, the Black Sea, and the Caspian Sea. It also occurs on the Atlantic side of North America. The conger has a wider range, extending from the western and southern shores of Britain and Ireland to the East Indian Archipelago and Japan. It is common in the Mediterranean.

The ovaries of the eel resemble somewhat these of the salmon in structure, not forming closed sacs, as in the majority of Teleostei, but consisting of laminæ exposed to the body cavity. The laminæ in which the eggs are produced are very numerous, and are attached transversely by their inner edges to a membranous band running nearly the whole length of the body-cavity. The majority of the eels captured for market are females with the ovaries in an immature condition. The male eel was first discovered in 1873 by Syrski at Trieste, the testis being described by him as a lobed elongated organ, in the same relative position as the ovary in the female, surrounded by a smooth surface without laminæ. He did not find ripe spermatozoa. He discovered the male by examining small specimens, all the larger being female. Jacoby, a later observer, found no males exceeding 19 inches in length, while the female may reach a length of 39 inches or more. Dr Petersen, in a paper published in 1896, states that in Denmark two kinds of eels are distinguished by the fishermen, namely, yellow eels and silver eels. The silver eels are further distinguished by the shape of the snout and the size of the eyes. The snout in front of the eyes is not flat, as in the yellow eels, but high and compressed, and therefore appears more pointed, while the eyes are much larger and directed outwards. In both kinds there are males and females, but Petersen shows that the yellow eels change into silver eels when they migrate to the sea. The sexual organs in the silver eels are more developed than in the yellow eels, and the former have almost or entirely ceased to take food. The male silver eels are from 11½ to 19 inches in length, the females from 16½ to about 39 inches. It is evident, therefore, that if eels only spawn once, they do not all reach the same size when they become sexually mature. The male conger was first described in 1879 by Hermes, who obtained a ripe specimen in the Berlin Aquarium. This specimen was not quite 2½ feet in length, and of the numerous males which have been identified at the Plymouth Laboratory, none exceeded this length. The large numbers of conger above this size caught for the market are all immature females. Female conger of 5 or 6 feet in length and weighing from 30 to 50 ℔ are common enough, and occasionally they exceed these limits. The largest recorded was 8 feet 3 inches long, and weighed 128 ℔.

There is every reason to believe that eels and conger spawn but once in their lives, and die soon after they have discharged their generative products. When kept in aquaria, both male and female conger are vigorous and voracious. The males sooner or later cease to feed, and attain to the sexually mature condition, emitting ripe milt when handled and gently squeezed. They live in this condition five or six months, taking no food, and showing gradual wasting and disease of the bodily organs. The eyes and skin become ulcerated, the sight is entirely lost, and the bones become soft through loss of lime. The females also after a time cease to feed, and live in a fasting condition for five or six months, during which time the ovaries develop and reach great size and weight, while the bones become soft and the teeth disappear. The female, however, always dies in confinement before the ova are perfectly ripe and before they are liberated from the ovarian tissue. The absence of some necessary condition, perhaps merely of the pressure which exists at the bottom of the sea, evidently prevents the complete development of the ovary. The invariable death of the fish in the same almost ripe condition leads to the conclusion that under normal conditions the fish dies after the mature ova have been discharged. Grassi states that he obtained ripe male eels, and ripe specimens of Muræna, another genus of the family, in the whirlpools of the Strait of Messina. A ripe female Muræna has also been described at Zanzibar. Gravid female eels, *i.e.*, specimens with ovaries greatly enlarged, have been occasionally obtained in fresh water, but there is no doubt that, normally, sexual maturity is attained only in the sea.

Until recent years nothing was known from direct observation concerning the reproduction of the common eel, or any species of the family. It was a well-known fact that large eels migrated towards the sea in autumn, and that in the spring small transparent eels of 2 inches in length and upwards were common on the shore under stones, and ascended rivers and streams in vast swarms. It was reasonable, therefore, to infer that the mature eels spawned in the sea, and that there the young were developed.

A group of peculiar small fishes were, however, known which were called Leptocephali, from the small proportional size of the head. The first of these described was captured in 1763 near Holyhead, and became the type of *L. Morrisii*, other specimens of which have been taken either near the shore or at the surface of the sea. Other forms placed in the same genus had been taken by surface fishing in the Mediterranean and in tropical ocean currents. The chief peculiarities of Leptocephali, in addition to the smallness of the head, are their ribbon-like shape and their glassy transparency during life. The body is flattened from side to side, and broad from the dorsal to the ventral edge. Like the eels, they are destitute of pelvic fins, and no generative organs have been observed in them (see Fig. above).



Leptocephali. (*By kind permission of J. & A. Churchill.*)

In 1864 the American naturalist, Gill, published the conclusion that *L. Morrisii* was the young or larva of the conger, and Leptocephali generally the young stages of species of Murænidæ. In 1886 this conclusion was confirmed from direct observation by Yves Delage, who kept alive in a tank at Roscoff a specimen of *L. Morrisii*, and saw it gradually transformed into a young conger. From 1887 to 1892 Professor Grassi and Dr Calandruccio carried on careful and successful researches into the development of the Leptocephali at Catania, in Sicily. The specimens were captured in considerable numbers in the harbour, and the transformation of *L. Morrisii* into young conger, and of various other forms of Leptocephalus into other genera of Murænidæ, such as *Muræna*, *Congromuræna*, and *Ophichthys*, was observed. In 1894 the same authors published the announcement that another species of Leptocephalus, namely, *L. brevirostris*, was the larva of the common eel. This larval form was captured in numbers with other Leptocephali in the strong currents of the Strait of Messina. In the metamorphosis of all Leptocephali a great reduction in size occurs. The *L. brevirostris* reaches a length of 8 cm., or a little more than 2½ inches, while the perfectly-formed young eel is 2 inches long or a little more.

The Italian naturalists have also satisfied themselves that certain pelagic fish eggs originally described by Raffaele at Naples are the eggs of Murænidæ, and that among them are the eggs of

Conger and Anguilla. They believe that these eggs, although free in the water, remain usually near the bottom at great depths, and that fertilization takes place under similar conditions. No fish eggs of the kind to which reference is here made have yet been obtained on the British coasts, although conger and eels are so abundant there. Raffaele described and figured the larva newly hatched from one of the eggs under consideration, and it is evident that this larva is the earliest stage of a Leptocephalus.

See "The Eel Question," *Report U.S. Commissioner of Fisheries for 1879.* Washington, 1882.—Cunningham, "Reproduction and Development of the Conger," *Journ. Mar. Biol. Assn.* vol. ii.—Petersen, *Report Dan. Biol. Station,* v., 1894.—Grassi, *Quart. Journ. Mic. Sci.* vol. xxxix., 1897. (J. T. C.)

**Eger,** the chief town of the government district of the same name in Bohemia; connected by rail with Nuremberg, Prague, Vienna, Reichenberg, &c. Population (1890), 18,658; (1900), 23,665, almost exclusively German (estimated at 91 per cent. Roman Catholic, 6 per cent. Protestant, and 3 per cent. Jewish). There is a garrison of 1069 men. Latterly Eger has been very prominent on account of its strong Pan-Germanic sentiment. The town is exceptionally interesting from its ancient buildings, collection of historical relics of Wallenstein, &c. There is a considerable textile industry, together with the manufacture of shoes, machinery, brewing, milling, &c. The inhabitants of the district are still distinguished from the surrounding population by their costumes, language, manners, and customs.

**Egham,** a town and railway station in the Chertsey parliamentary division of Surrey, England, on the Thames, 21 miles west by south of London by rail. The parish church contains monuments by Flaxman. Within the parish are the Royal Indian Engineering College on Cooper's Hill, the hill celebrated in Sir John Denham's poem, 1642, the Royal Holloway College for Women, the Holloway sanatorium for the treatment of mental ailments, and a cottage hospital; also the field of Runnymede, where King John signed Magna Carta, and (partly in Berkshire) Virginia Water, a large artificial lake in the south of Windsor Great Park. Area of parish (with Englefield), 7786 acres. Population (1881), 8692; (1901), 11,894.

**Egin** (Armenian, *Agn,* "the spring"), an important town in the Memuret el-Aziz viláyet of Asiatic Turkey (altitude, 3300 feet). It is picturesquely situated in a theatre of lofty, abrupt rocks, on the right bank of the Western Euphrates, at the point where the Kharpút-Erzingan road crosses the river by a wooden bridge. The stone houses stand in terraced gardens and orchards, and the streets are mere rock-ladders. The population numbers 10,000 (Moslems 6000, Armenians 4000). Egin was settled by Armenians who emigrated from Van in the 11th century with Senekherim. On 8th November 1895 many Armenians were massacred.

**Egorievsk,** a district town of Russia, government and 74 miles north-east of Ryazañ, connected by a branch line (14 miles) with the Moscow to Ryazañ main line. Its cotton mills (yielding over £500,000 a year) and other factories give occupation to 6000 persons. It has important fairs for trade in grain, hides, &c., exported. Population, 20,000.

# EGYPT.

## Geography and Statistics.

The salient physical features of Egypt may be grouped as follows, each division having its own characteristic features, due essentially to the geological structure of the country:—(1) the Delta, (2) the Trough or "Rift" Valleys, (3) the Desert Plateaux, (4) the mountainous region in the east and north-east. The Nile must also be considered separately.

*The Delta.*—The delta of the Nile occupies a triangular area north of Cairo, measuring 100 miles from south to north, and having a width of 155 miles on the shore of the Mediterranean between Alexandria on the west and Port Said on the east. Beyond these two points the low hills of the desert form the coast-line, while between them the low sandy shore of the delta, slowly increasing by the annual deposit of silt by the river, is a barren area of sand hills and salty waste land, except in a few parts where reclamation has already made progress. Southwards the quality of the soil rapidly improves, and becomes the most fertile part of Egypt. This area is watered by the Damietta and the Rosetta branches of the Nile, and by the network of canals which, beginning at Cairo and the Barrage, intersects the whole delta and extends eastwards through the Wadi Tumilat as far as Suez. The soil of the delta is a dark grey fine sandy soil, becoming at times almost a stiff clay by reason of the fineness of its particles, which consist almost wholly of extremely small grains of quartz with a few other minerals, and often numerous flakes of mica. This deposit varies in thickness, as a rule, from 55 to 70 feet, at which depth it is underlain by a series of coarse and fine yellow quartz sands, with occasional pebbles, or even banks of gravel, while here and there thin beds of clay occur. These sand-beds are sharply distinguished by their colour from the overlying Nile deposit, and are of considerable thickness. A boring made in 1886 for the Royal Society at Zagazig attained a depth of 375 feet without reaching rock, and another, recently sunk near Lake Abukir (close to Alexandria) by a company, reached a depth of 405 feet with the same result. Numerous other borings to depths of 100 to 200 feet have given similar results, showing the Nile deposit to rest generally on these yellow sands, which provide a constant though not a very large supply of good water; near the northern limits of the delta this cannot, however, be depended on, since the well water at these depths has proved on several occasions to be salt. The surface of the delta is a wide alluvial plain sloping gently towards the sea, and having an altitude of 29 feet above it at its southern extremity. The only inequalities are the mounds, formed of ruined mud-brick dwellings, which mark the site of ancient towns, or on which the present towns and villages stand, occupying often the same site as their predecessors of earlier times. Its limits east and west are determined by the higher ground of the deserts, to which the silt-laden waters of the Nile in flood time cannot reach.

*The Valleys.*—The valleys, which are a remarkable feature of the country, are those occupied respectively by the Nile, the Gulf of Suez, and the Gulf of Akaba, and each of these is a rift-valley determined by the subsidence of a narrow belt in the neighbourhood of a line of fracture on the earth's surface. In the Gulf of Suez, certainly, an upward movement is still in progress, as salines along the coast are still being formed as the land rises; but in the Nile Valley north of Assuan this is more difficult to determine, though certain slight local earthquake shocks, which occasionally occur, seem to point to the fact that that movement has not wholly ceased. The trough so

formed has been filled by deposits of coarse and fine sand and gravel, containing numerous fragments of igneous rocks, which underlie the present Nile mud deposit, as in the Delta; and similarly, also, deep borings have reached no rock-floor up to the present. At Beni Suef, with the Tertiary limestone plateaux of the desert 3 miles distant, 400 feet of sands and clays were penetrated without any sign of rock, and at Medinet el Fayum a boring of 450 feet gave the same result.

Entering Egypt proper, a little to the north of the Second Cataract, the Nile flows through a valley in sandstone beds of Cretaceous age as far as latitude 25° N., and throughout this part of its course the valley is extremely narrow, rarely exceeding 2 miles in width. At two points, namely, Kalabsha and Assuan (First Cataract), its course is interrupted by outcrops of granites and other crystalline rocks, which have been uncovered by the erosion of the overlying sandstone, and to-day form the mass of islands, with numerous small rapids, which have been described not very accurately as cataracts; no good evidence exists in support of the view that they are the remains of a massive barrier, broken down and carried away by some sudden convulsion. From latitude 25° N. northwards for 518 miles the valley is of the "rift-valley" type, a level depression in the limestone plateau, enclosed usually by steep cliffs, except where the tributary valleys drained into the main valley in early times, when there was a larger rainfall, and which now carry off the occasional rainstorms that burst on the desert. The average width of the cultivation is about 10 miles, of which the greater part lies on the left bank of the river; and outside this is a belt, varying from a few hundred yards to 3 or 4 miles, of stony and sandy ground, reaching up to the foot of the limestone cliffs, which rise in places to as much as 1000 feet above the valley. This continues as far as latitude 29° N., after which the hills that close in the valley become lower, and the higher plateaux lie at a distance of 10 or 15 miles back in the desert. The fertile province of the Fayum, on the left bank of the Nile and separated from it by 6 miles of desert, seems to owe its existence to movements similar to those which determined the valley itself. Surrounded by Tertiary limestone strata on the north, west, and south, the boring above mentioned met with no representatives of these beds in the 450 feet which were penetrated. Lying in a basin sloping in a series of terraces from an altitude of 65 feet above sea-level in the east to about 140 feet *below* sea-level on the north-west, at the margin of the Birket-el-Kerun, this province is wholly irrigated by a large canal, the Bahr Yusef, which, leaving the Nile at Deirut in Upper Egypt, follows the western margin of the cultivation in the Nile Valley, and at length enters the Fayum through a gap in the desert hills by the XIIth Dynasty pyramids of Lahun and Hawara.

*The Desert Plateaux.*—Speaking generally, Egypt consists of a broad plateau of sedimentary rocks, lying on the western side of a band of crystalline rocks which occupy the southern part of the peninsula of Sinai and the western side of the Red Sea from latitude 29° N. southwards. In the north, where beds of Upper Tertiary age occur, the desert plateaux are comparatively low, but from Cairo southwards, as the Eocene limestones come in, they rise to 1000 and even 1500 feet above sea-level. Formed mostly of horizontal strata of varying hardness, they present a series of terraces of minor plateaux, rising one above the other, and intersected by small ravines worn by the occasional rainstorms which burst in their neighbourhood. The weathering of this desert area is probably fairly rapid, and the agents at work are principally the rapid heating and cooling of the rocks by day and night, and the erosive action of sand-laden wind on the softer layers; these, aided by the occasional rain, are ceaselessly at work, and produce the successive plateaux, dotted with small isolated hills and cut up by valleys (wadis), which occasionally become deep ravines, thus forming the principal type of scenery of these deserts. From this it will be seen that the desert in Egypt is mainly a rock desert, where the surface is formed of disintegrated rock, the finer particles of which have been carried away by the wind; and east of the Nile this is almost exclusively the case. In the western desert, however, those large sand accumulations which are usually associated with a desert are met with. They occur as lines of dunes formed of rounded grains of quartz, and lie in the direction of the prevalent wind, usually being of small breadth as compared with their length; but in certain areas, such as that lying south-west and west of the Oases of Farafreh and Dakhleh, these lines of dunes, lying parallel to each other and about half a mile apart, cover immense areas, rendering them absolutely impassable except in a direction parallel to the lines themselves. East of the Oases of Baharieh and Farafreh is a very striking line of these sand dunes; rarely more than 3 miles wide, it extends almost continuously from Moghara in the north, passing along the west side of Khargeh Oasis to a point near the Nile in the neighbourhood of Abu Simbel in Nubia—having thus a length of nearly 550 miles. In the northern part of this desert the dunes lie about N.W.–S.E., but farther south incline more towards the meridian, becoming at last very nearly north and south.

*Oases.*—In the western desert lie the five large oases of Egypt, namely, Siwah, Baharieh, Farafreh, Dakhleh, and Khargeh, occupying depressions in the plateau or, in the case of the last three, large indentations in the face of the escarpment formed by the Lower Eocene and Upper Cretaceous Limestones. Their fertility is due to a plentiful supply of water furnished by a sandstone bed 300 to 500 feet below the surface, whence the water rises through natural fissures or artificial boreholes to the surface, and sometimes to several feet above it. These oases were known and occupied by the Egyptians as early as 1600 B.C., and Khargeh rose to special importance at the time of the Persian occupation.

*The Mountainous Region.*—The mountainous part of the country is that occupied by the crystalline rocks in the southern part of Sinai, and the belt occupying the western shore of the Gulf of Suez and Red Sea, where the principal peaks rise to heights of 6000 and 7000 feet. Owing to the slight rainfall, and the rapid weathering of the rocks by the great range of temperature, these hills rise steeply from the valleys at their feet as almost bare rock, supporting hardly any vegetation. In some of the valleys, wells or rock-pools filled by rain occur, and furnish drinking-water to the few Arabs who wander in these hills. Farther south, where the rainfall is greater, the valleys are more fertile, and support considerable numbers of camels, sheep, and goats.

*The Egyptian Nile.*—The Nile (*q.v.*) enters Egypt proper a little to the north of the Second Cataract, and between there and the First Cataract has a length of 200 miles and a slope of $\frac{1}{12500}$. From this point to the Barrage at the apex of the Delta the length is 605 miles and the slope $\frac{1}{13000}$, and thence to the sea, by either the Rosetta or Damietta branch, is 145 miles more. The Nile is at its lowest at Assuan at the end of May, then rises slowly until the middle of July, and rapidly throughout August, reaching its maximum at the beginning of September; it then falls slowly through October and November. At Cairo the lowest level is reached about the middle of June, after which the rise is slow in July and fairly rapid in August, reaching the maximum at the beginning of

October. In the month of June the water is clear and carries practically no suspended matter, but by August it is full of dark red-brown sediment brought down by the Blue Nile and the Atbara from the plateaux of Abyssinia, and is estimated to be then carrying 8 cubic yards per second; by September this has been reduced to half the amount, and then diminishes rapidly. On the island of Elephantine at Assuan is the well-known Nilometer, dating from ancient Egyptian times, and altered and extended in Roman times, while the remains of other ancient Nilometers exist at Philæ, Edfu, and Esna, together with inscriptions recording about forty high Niles in the XXVth Dynasty, recently discovered on a quay wall of the temple of Karnak. The data furnished by these give about 4½ inches per century as the rate at which the Nile is silting up its bed north of the First Cataract.

*Climate.*—Except a narrow belt on the north along the Mediterranean shore, Egypt lies in an almost rainless area, where the temperature is high by day and sinks quickly at night in consequence of the rapid radiation under the cloudless sky. The mean temperature at Alexandria and Port Said varies between 57° F. in January and 81° F. in July; while at Cairo, where the proximity of the desert begins to be felt, it is 53° F. in January, rising to 84° F. in July. January is the coldest month, when occasionally in the Nile Valley, and more frequently in the open desert, the temperature sinks to 32° F., or even a degree or two below. The mean maximum temperatures are 99° F. for Alexandria and 110° F. for Cairo. Farther south the range of temperature becomes greater as pure desert conditions are reached.

*Mean Temperature.*

| Place. | January. | July. | Year. | Annual Maximum. | Annual Minimum. |
|---|---|---|---|---|---|
| Assuan | 62° | 95° | 80° | 118° | 42° |
| Wadi Halfa | 61 | 93 | 79 | 117 | 41 |
| Khartum | 71 | 93 | 84 | 114 | ... |

The relative humidity varies greatly. At Assuan the mean value for the year is only 38 per cent., that for the summer being 29 per cent. and for the winter 51 per cent.; while for Wadi Halfa the mean is 32 per cent., and 20 per cent. and 42 per cent. are the mean values for summer and winter respectively. In Alexandria and on all the Mediterranean coast of Egypt rain falls abundantly in the winter months, amounting to 8 inches in the year; but southwards it rapidly decreases, and south of latitude 31° N. but little falls.

*Rainfall.*

| Place. | Inches per Annum. |
|---|---|
| Alexandria | 8·1 |
| Port Said | 3·4 |
| Ismailia | 2·1 |
| Suez | 1·1 |

Recent records at Cairo show that the rainfall is very irregular, and is furnished by occasional storms rather than by any regular rainy season; still, most falls in the winter months, especially December and January, while, on the other hand, none has been recorded in June and July.

*Rainfall in Cairo in Inches.*

| | 1887. | 1888. | 1889. | 1890. | 1891. | 1892. | 1893. | 1894. | 1895. | 1896. | 1897. | 1898. |
|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Inches | 0·86 | 1·73 | 0·64 | 2·15 | 1·60 | 0·27 | 1·30 | 0·66 | 1·70 | 1·43 | 0·3 | 16·1 |

In the open desert rain falls even more rarely, but it is by no means unknown, and from time to time heavy storms burst, causing sudden floods in the narrow ravines, and often drowning both men and animals. These are more common in the mountainous region of the Sinai Peninsula, where they are much dreaded by the Arabs. Snow is unknown in the Nile Valley, but on the mountains of Sinai and the Red Sea Hills it is not uncommon, and a temperature of 18° F. at an altitude of 2000 feet has been recorded in January.

The atmospheric pressure varies between a maximum in January and a minimum in July, the mean difference being about 0·29 inch. The following are the mean values for Cairo for the years 1885–1898:—

| Year. | Temp. ° Fahr. | Atmospheric Pressure. Inches. | Year. | Temp. ° Fahr. | Atmospheric Pressure. Inches. |
|---|---|---|---|---|---|
| 1885 | 70·3 | 29·84 | 1892 | 70·3 | 29·89 |
| 1886 | 69·6 | 29·86 | 1893 | 68·4 | 29·89 |
| 1887 | 70·6 | 29·87 | 1894 | 69·2 | 29·87 |
| 1888 | 71·6 | 29·87 | 1895 | 69·5 | 29·87 |
| 1889 | 72·0 | 29·88 | 1896 | 69·5 | 29·87 |
| 1890 | 71·5 | 29·84 | 1897 | 68·5 | 29·90 |
| 1891 | 71·4 | 29·88 | 1898 | 68·7 | 29·88 |

The most striking meteorological factor in Egypt is the persistence of the north wind throughout the year, without which the climate would be very trying. In December, January, and February, at Cairo, the north wind slightly predominates, though those from the south and west often nearly equal it, but after this the north blows almost continuously throughout the year. In May and June the prevailing direction is north and north-northeast, and for July, August, September, and October north and north-west. From the few observations that exist, it seems that farther south these southern winter winds decrease rapidly, becoming westerly, until at Assuan and Wadi Halfa the northerly winds are almost invariable throughout the year. The *Khamsin*, or hot sand-laden winds of the spring months, come invariably from the south. They are preceded by a rapid fall of the barometer for about a day, until a gradient from south to north is formed, then the wind commences to blow, at first gently, from the south-east; rapidly increasing in violence, it shifts through south to south-west, finally dropping about sunset. The same thing is repeated on the second and sometimes the third day, by which time the wind has worked round to the north again. During a Khamsin the temperature is high and the air extremely dry, while the dust and sand carried by the wind form a thick yellow fog obscuring the sun. The southern winds of the summer months which occur in the low latitudes north of the equator are not felt much north of Khartum.

*Minerals.*—The minerals of Egypt which are worked at present are very few. The salines at Meks, near Alexandria, supply all the salt needed for the country, except a small quantity used for curing fish at Lake Menzaleh; while the lakes in the Wadi Natron, 45 miles north-west of the pyramids of Gizeh, furnish carbonate of soda in large quantities. The alum of the Western Oases is no longer worked, on account of the cost of transport. The turquoise mines of Sinai, in the Wadi Moghara, are worked regularly by the Arabs of the peninsula, who sell the stones in Suez; while the emerald mines of Jebel Zubara, south of Kosseir, have been recently examined, to see if they could be profitably worked. Petroleum occurs at Jebel Zeit, on the west shore of the Gulf of Suez, but up to the present attempts to obtain it in any quantity have not proved successful. Considerable veins of hæmatite of good quality occur both in the Red Sea Hills and in Sinai, but difficulty of transport and want of fuel render them unimportant.

*Flora.*—Since practically the whole of the country which will support vegetable life is under cultivation, the flora of Egypt is limited. Besides the industrial crops cultivated throughout the country, the most important tree is the date palm, which grows all over Egypt and in the Oases. The dom palm is first seen a little north of latitude 26° N., and extends southwards. The vine grows well, and in ancient times was largely cultivated for wine; oranges, lemons, and pomegranates also abound. The sunt tree (*Acacia Nilotica*) grows everywhere, as well as the tamarisk and the sycamore. In the deserts several kinds of thorn bushes grow; and wherever rain or springs have moistened the ground, numerous wild flowers thrive. This is especially the case where there is also shade to protect them from the midday sun, as in some of the narrow ravines in the eastern desert and in the palm groves of the oases, where various ferns and flowers grow luxuriantly round the springs. Of late years new avenues and gardens have been extensively planted, especially near the towns; and among many trees which have been imported, the "lebbek" (*Albizzia Lebbek*) thrives especially, and has been very largely employed.

*Fauna.*—Besides the ordinary domestic animals, the camel, horse, donkey, goat, sheep, cow, water buffalo, &c., there are few wild animals. The principal are the hyæna, jackal, and fox; numerous gazelles in the deserts; the ibex in Sinai and the Red Sea Hills; and rarely the moufflon, or maned sheep, is met. The crocodile is never

now seen in Egypt. Birds are fairly numerous, and include eagles, vultures, kites, owls, as well as several kinds of plover; sand grouse and pigeons are abundant, the latter being kept for their dung, which is used as manure. Quails arrive from the north about September, and return in the spring, passing through Egypt in February and March. Aquatic birds are very numerous—pelicans, storks, cranes, herons, geese, and duck.

*Area and Population.*—The total area of Egypt proper, including the Oases in the Libyan Desert, the regions between the Nile and the Red Sea, and El-Arish in Syria, but excluding the Sudan, is about 400,000 square miles; but the cultivated and settled area, that is, the Nile Valley and Delta, covers only 12,980 square miles. Canals, roads, date plantations, &c., cover 1900 square miles; 2850 square miles are comprised in the surface of the Nile, marshes, lakes, and desert.

The population is generally divisible into—

(1) The fellahin, or the peasant population of the Nile Valley;
(2) The Beduin, or nomad Arabs of the desert;
(3) The Nuba or Berberin, inhabitants of the Nile Valley between Assuan and Dongola.

The first of these includes both the Moslem and Coptic inhabitants, who have probably changed but little since ancient Egyptian times, in spite of their conquest at different periods by various nations, each of whom has left but little mark on the inhabitants, except the change of religion.

The Beduin, or the Arabs of the desert, are of two different classes: first, the Arabic-speaking tribes, who have probably immigrated from Arabia and Syria, and who occupy the deserts as far south as latitude 26° N.; secondly, the tribes who occupy the desert from Kosseir to Suakin, namely, the Hadendoa, Bisharin and the Ababda tribes, who speak a language of their own, and are probably the descendants of the Blemmyes, who occupied these parts in ancient times.

The population according to the census of 1897 was 9,734,405, compared with 6,813,919 in 1882, being an increase of 43·5 per cent. in 15 years. In the two following tables are given the numbers for Upper and Lower Egypt, as well as the number of foreigners resident in the country; while in others are given the division by sex and mode of life, taken from the census of 1897:—

| | 1882. | 1897. | Increase per cent. in 15 Years. |
|---|---|---|---|
| Population of Lower Egypt | 4,008,746 | 5,676,109 | 41·5 |

Egypt is divided into 6 governorships and 14 provinces, of which 6 belong to Lower Egypt and 8 to Upper Egypt.

The governorships are: Cairo, Alexandria, Damietta, Suez Canal, Suez, El-Arish.

Lower Egypt includes the provinces of: Behera, Gharbieh, Menufieh, Dakahlieh, Kaliubieh, Charkieh.

Upper Egypt: Gizeh, Beni Suef, Fayum, Minia, Assiut, Girgeh, Keneh, Assuan.

The following tables give the population of each governorship and province, with the number of persons per square mile in each:—

| | Area in Square Miles. | Population, 1882. | Population, 1897. | Population per Sq. Mile, 1897. |
|---|---|---|---|---|
| GOVERNORSHIPS. | | | | |

[1] Without Arabs, who were included in the figures for 1897.

*Government and Administration.*—The Central Government consists of the Khedive, together with a Council of six Ministers of State, under the presidency of a Prime Minister. To these is added the British Financial Adviser, who attends all meetings of the Council of Ministers, but has not a vote; on the other hand, no financial decision may be taken without his consent. The Ministries are those of the Interior, Finance, Public Works, Justice, War, and Public Instruction, and in each of these are prepared the drafts of decrees, which are then submitted to the Council of Ministers for approval, and on being signed by the Khedive become law. The control of the different parts of the country is carried on by governors of the governorships, and *mudirs* of the provinces, each of whom is under the Ministry of the Interior. The provinces are further divided into districts, each of which is under a *mamur*, who in his turn supervises and controls the *omda*, or head-man, of each village in his district.

*Justice.*—In Egypt there are four judicial systems:—(1) the *Mekhemehs* or courts of the religious law, concerned

mainly with questions affecting the personal status of Mahommedans; (2) the Mixed Courts, instituted in 1875, dealing with civil actions between persons of different nationalities, and to some extent with criminal offences of foreigners; (3) the Consular Courts, where foreigners accused of crime are tried; (4) the Native Courts, for civil actions between natives or crimes by natives. The Native Courts, instituted 1884–89, with both foreign and native judges, now consist of 6 courts of first instance, an appeal court at Cairo, and 42 summary courts for cases of moderate importance. With special reference to these tribunals a British judicial adviser was appointed in 1891. A committee of judicial surveillance watches the working of the courts of first instance and the summary courts, and endeavours, by letters and discussions, to maintain purity and sound law. There is a *Procureur-Général*, who, with other duties, is entrusted with criminal prosecutions. His representatives are attached to each tribunal, and form the "parquet" under whose orders the police act in bringing criminals to justice. The police service, which has been subject to frequent modification, was in 1895 put under the orders of the Ministry of the Interior, to which a British adviser and British inspectors are attached. The provincial police is under the direction of the local authorities, the *mudirs* or governors of provinces, and the *mamurs* or district officials; to the *omdas* or village headmen, who are responsible for the good order of the villages, a limited criminal jurisdiction has been entrusted.

*Religion.*—The religion of the country is essentially Moslem, and its adherents far outnumber those of all other creeds. The Christians are mostly of the Orthodox Greek Church. Jews are not very numerous, and are mostly found in the towns. In the following table, under the heading Orthodox are included Orthodox Copts, Orthodox Greeks, Greek Orthodox Syrians, and Orthodox Armenians; while with the Catholics are included Roman Catholics, Coptic Catholics, Syrian Catholics, Maronites, and Armenian Catholics:—

| Creed. | Lower Egypt. | Per cent. | Upper Egypt. | Per cent. | Total. | Per cent. |
|---|---|---|---|---|---|---|
| Mahommedans . | 5,407,794 | 95·3 | 3,569,908 | 88·0 | 8,977,702 | 92·2 |
| *Christians*— | | | | | | |
| Orthodox . | 174,516 | 3·0 | 471,259 | 11·6 | 645,775 | 6·6 |
| Catholic . | 56,660 | 1·0 | 4,391 | ·1 | 61,051 | ·6 |
| Protestant | 11,901 | 0·2 | 12,508 | ·3 | 24,409 | ·3 |

| Jews . | 24,973 | 0·5 | 227 | ... | 25,200 | ·3 |
| Various . | 265 | ... | 3 | ... | 268 | ... |

*Education.*—Under the Ministry of Public Instruction there is now a graduated system of teaching, commencing with the "kuttabs" or village schools attached to mosques, passing on to the primary and secondary schools, and finally the two technical schools, and the schools of agriculture, medicine, and law. Besides these there are nine missionary and other schools of all grades. In 1898 there were in all 9702 kuttabs, with 14,700 teachers for the 183,470 pupils who attend them; but only a few of these, at present about 100, are under Government inspection and receive the grant in aid to which it entitles them. In the rest the education given is of small value. There were 240 higher grade primary schools, and 28 secondary schools, besides 3 training colleges for teachers. The University of El-Azhar attracts students to the number of nearly 8000, of whom some 2000 are resident, from all parts of the Mahommedan world. Including this and the 3 training colleges, there are 26 higher or professional schools, with 486 teachers and 12,706 students. In 1897, of the sedentary Egyptian population over seven years of age, there could read and write in Lower Egypt 7 per cent., in Upper Egypt, 4·07 per cent., in all Egypt, 5·8 per cent.; of the foreign population over seven years of age in all Egypt, 74 per cent. could read and write.

*Agriculture.*—The total area of land, either cultivated, under reclamation, or which may later be reclaimed, is 6,250,000 acres, of which 4,690,000 pay full taxes, and 1,060,000 are in course of reclamation, paying a proportional tax. The remaining 500,000 acres are still waste land. The most important crops are those of cotton and sugar.

The seasons for agriculture are—

Summer, from 1st April to 1st August.
Flood, ,, 1st August ,, 1st December.
Winter, ,, 1st December ,, 1st April.

The approximate area and average yield in each season is as follows:—

| Season. | Area in Acres. | Yield. |
|---|---|---|
| | | £E. |
| Summer . . . | 2,046,500 | 15,177,500 |
| Flood . . . | 1,510,000 | 6,870,000 |
| Winter . . . | 4,260,000 | 17,013,000 |

The crops cultivated in the different seasons are as follows:—

*Upper Egypt.*

| Season. | Crop. | Area. | Value |
|---|---|---|---|
| | | Acres. | £E. |
| Summer . . | Sugar-cane . | 75,000 | 1,200,000 |
| | Cotton . . | 110,000 | 1,100,000 |
| | Vegetables, &c. | 15,000 | 150,000 |
| | Melons . . | 12,500 | 127,500 |
| | Sorghum . . | 160,000 | 960,000 |
| Flood . . . | Dates . . | 5,200,000 | 1,040,000 |
| | Sorghum . . | 510,000 | 2,040,000 |
| | Rice . . | 20,000 | 80,000 |
| Winter . . . | Wheat . . | 600,000 | 3,000,000 |
| | Beans . . | 500,000 | 2,145,000 |
| | Clover . . | 500,000 | 2,000,000 |
| | Barley . . | 250,000 | 875,000 |
| | Lentils . . | 140,000 | 420,000 |
| | Flax . . | 1,000 | 8,000 |
| | Onions . . | 15,000 | 150,000 |
| | Vetches . . | 115,000 | 290,000 |

Double cropped area = 703,500 acres.

*Lower Egypt.*

| Season. | Crop. | Area | Value. |
|---|---|---|---|
| | | Acres. | £E. |
| Summer . . | Cotton . . | 1,500,000 | 10,500,000 |
| | Sugar-cane . | 4,000 | 40,000 |
| | Vegetables, &c. | 70,000 | 700,000 |
| | Rice . . | 100,000 | 400,000 |
| Flood . . . | Dates . . | 2,200,000 | 440,000 |
| | Maize . . | 900,000 | 3,150,000 |
| | Rice . . | 80,000 | 120,000 |
| Winter . . . | Wheat . . | 600,000 | 2,700,000 |
| | Barley . . | 330,000 | 660,000 |
| | Clover . . | 955,000 | 3,395,000 |
| | Beans . . | 180,000 | 630,000 |
| | Vegetables, &c. | 70,000 | 700,000 |
| | Flax . . | 4,000 | 40,000 |

Double cropped area = 1,363,000 acres.

The following table gives the cotton and sugar crops for twenty years:—

| Year. | Cotton Crop in Cantars 98 1 lb. | Sugar-Cane in Tons. |
|---|---|---|
| 1878 | 1,700,000 | ... |
| 1890 | 4,100,000 | 52,000 |
| 1894 | 4,600,000 | 62,000 |
| 1895 | 5,200,000 | 83,000 |
| 1896 | 5,800,000 | 91,000 |
| 1897 | 6,500,000 | 74,000 |
| 1898 | 5,600,000 | ... |

In Upper Egypt there are 1,731,800 acres under flood irrigation, and 587,500 acres under perennial irrigation; while in Lower Egypt 3,437,800 acres are dependent on the great perennial canals. The ownership of the land is shown in the following table:—

| Class. | Acres owned by | |
|---|---|---|
| | Upper Egypt. | Lower Egypt. |
| State Domains | 47,399 | 192,910 |
| Daïra Sanieh | 306,955 | 31,581 |
| Religious Bodies | 16,622 | 56,638 |
| Banks, Foreigners, &c. | 64,645 | 519,537 |
| Non-Resident Egyptians | 394,808 | 1,982,558 |
| Resident Egyptians | 1,488,905 | 1,654,603 |

The land is everywhere subdivided into extremely small plots, each of which is often owned by the members of a family, each having a share. Out of 767,260 proprietors of land in 1897, 611,074 owned less than 5 acres. Cattle and farm animals, including horses and camels, number 1,669,000.

The only fisheries of importance are those of Lake Menzaleh, which produce a net revenue of about £E.60,000 annually.

*Commerce.*—Since 1875 the commerce has increased rapidly. Great Britain is the largest importer and exporter, and next come France, Turkey, Russia, Austria, and the United States, though the trade of Germany and Belgium is also rapidly increasing.

The exterior commerce, comprising imports and exports of all kinds of merchandise and of specie, is given at the following figures since 1880:—

| Year. | Merchandise. | | Specie. | |
|---|---|---|---|---|
| | Imports. | Exports. | Imports. | Exports. |
| | £E. | £E. | £E. | £E. |
| 1880 | 6,549,933 | 12,983,203 | 4,791,700 | 405,600 |
| 1890 | 8,081,297 | 11,876,086 | 2,971,461 | 2,085,455 |
| 1895 | 8,389,933 | 12,632,450 | 4,319,265 | 2,322,190 |
| 1897 | 10,603,672 | 12,321,220 | 2,921,722 | 2,369,479 |
| 1898 | 11,033,219 | 11,805,179 | 2,730,116 | 1,891,513 |
| 1899 | 11,441,802 | 15,350,908 | 4,515,917 | 1,502,485 |
| 1900 | 14,112,369 | 16,766,609 | 4,114,612 | 2,602,790 |

The following table shows the value of the commercial intercourse of Egypt with different foreign countries in 1900:—

| Country. | Imports from. | Exports to. |
|---|---|---|
| | £E. | £E. |
| Great Britain | 5,300,447 | 9,141,932 |
| British Colonies in the Mediterranean | 144,431 | 4,404 |
| British Colonies in the Extreme East | 696,351 | 187,813 |
| Germany | 485,933 | 900,824 |
| America | 289,331 | 1,035,600 |
| Austria-Hungary | 900,958 | 642,477 |
| Belgium | 494,751 | 126,165 |
| China and Extreme East | 124,198 | 149,347 |
| France and Algeria | 1,314,869 | 1,430,153 |
| Greece | 121,468 | 5,246 |
| Italy | 661,347 | 601,496 |
| Morocco | 40,157 | 2,692 |
| Persia | 42,778 | 4,642 |
| Russia | 608,901 | 1,209,563 |
| Turkey | 2,220,966 | 290,193 |
| Other countries | 354,505 | 1,030,136 |
| Total | 13,801,391 | 16,757,683 |

The value of the leading exports and imports of Egypt in 1900 is shown in the following table:—

| Merchandise. | Imports. | Exports. |
|---|---|---|
| | £E. | £E. |
| Animals and animal food products | 652,357 | 129,733 |
| Skins and leather goods | 206,860 | 84,855 |
| Other animal products | 84,373 | 41,611 |
| Cereals, vegetables, &c. | 1,532,341 | 2,615,433 |
| Provisions and drugs | 404,735 | 676,226 |
| Spirits, oils, &c. | 815,888 | 16,318 |
| Rags, paper, books | 177,103 | 15,690 |
| Wood and coal, cane-work, &c. | 2,093,061 | 16,350 |
| Stone, lime, glass, &c. | 399,008 | 1,528 |
| Dyeing materials, &c. | 282,875 | 21,112 |
| Chemical products | 276,509 | 15,547 |
| Textiles,[1] mainly raw cotton | 4,011,498 | 13,104,860 |
| Metals and metal goods | 1,817,971 | 5,691 |
| Sundries | 439,609 | 12,689 |
| Tobacco | 577,203 | ... |
| Total | 13,801,391 | 16,757,683 |

[1] In 1897 the cotton tissues imported amounted to £E.1,798,600; and in 1900 to £E.1,987,095. In the cotton season of 1896-97 the quantity of raw cotton exported was 5,177,495 cantars, valued at £E.10,088,838; in 1897-98, 5,764,636 cantars, valued at £E.9,040,150; in 1898-99, 6,001,222 cantars, valued at £E.11,598,222; and in 1899-1900, 4,868,596 cantars, valued at £E.13,039,003.

The receipts from tobacco were: in 1896, £E.1,006,526; in 1897, £E.1,044,780; in 1898, £E.1,080,669; in 1899, £E.1,068,497.

Of the total imports in 1899 the value of £E.9,945,165, and of the exports the value of £E.15,068,722, passed through the port of Alexandria.

*Shipping and Navigation.*—The following tables show the nationality and tonnage of vessels arriving and clearing at Alexandria. Great facilities have been afforded to steamers since the completion of the docks, wharves, and quays; and in order still further to facilitate navigation the Government have constructed a new pass, 300 feet wide, to enable vessels, which have often been delayed off the port during stormy weather, to make a direct run into harbour. The new pass, 30 feet deep, was opened to navigation in July 1894.

Arrivals and clearances of commercial vessels at Alexandria in five years:—

| Year. | Arrivals. | | Clearances. | |
|---|---|---|---|---|
| | Vessels. | Tons. | Vessels. | Tons. |
| 1895 | 2393 | 2,206,667 | 2339 | 2,194,964 |
| 1896 | 2132 | 2,123,591 | 2105 | 2,094,684 |
| 1897 | 2203 | 2,267,120 | 2143 | 2,270,836 |
| 1898 | 2454 | 2,555,396 | 2428 | 2,559,876 |
| 1899 | 2805 | 2,414,674 | 2758 | 2,389,058 |

The following table shows the nationality of commercial vessels arrived and cleared in 1898, and the totals for 1899:—

| Nationality. | Arrivals. | | Clearances. | |
|---|---|---|---|---|
| | Vessels. | Tons. | Vessels. | Tons. |
| British | 729 | 1,111,481 | 734 | 1,117,161 |
| French | 125 | 263,778 | 126 | 265,314 |
| Austrian | 139 | 254,703 | 140 | 261,125 |
| Turkish | 847 | 151,461 | 827 | 147,487 |
| Russian | 95 | 185,940 | 95 | 188,971 |
| Italian | 153 | 281,373 | 153 | 279,426 |
| Greek | 163 | 66,781 | 155 | 63,755 |
| Swedish and Norwegian | 36 | 59,221 | 34 | 57,809 |
| German | 27 | 52,230 | 27 | 54,754 |
| Egyptian | 82 | 85,547 | 79 | 82,566 |
| Other countries | 58 | 43,881 | 58 | 41,508 |
| Total for 1898 | 2454 | 2,556,396 | 2428 | 2,559,876 |
| Total for 1899 | 2805 | 2,414,674 | 2758 | 2,389,058 |

*Suez Canal.*—The following table shows the number and gross tonnage of vessels of all nationalities that passed through the Canal in 1898 :—

| Country. | No. | Gross Tonnage. |
|---|---|---|
| Great Britain | 2295 | 8,691,093 |
| Germany | 356 | 1,353,161 |
| France | 221 | 891,642 |
| Holland | 193 | 526,478 |
| Austria-Hungary | 85 | 300,251 |
| Japan | 46 | 261,602 |
| Russia | 48 | 243,381 |
| Spain | 49 | 232,358 |
| Italy | 74 | 208,418 |
| Norway | 47 | 109,709 |
| Turkey | 54 | 83,541 |
| Denmark | 8 | 30,228 |
| Egypt | 10 | 15,705 |
| China | 4 | 6,181 |
| America | 4 | 3,162 |
| Greece | 2 | 1,941 |
| Rumania | 1 | 1,703 |
| Sweden | 2 | 1,021 |
| Portugal | 3 | 606 |
| Argentine Republic | 1 | 451 |
| Total | 3503 | 12,962,632 |

In 1899 the British ships numbered 2310, with a tonnage of 9,046,031 ; and the German 387, with a tonnage of 1,492,657.

The number and gross tonnage of vessels that have passed through the Suez Canal, and the gross receipts of the company, were as follow during the twenty years after 1880 :—

| Year. | No. of Vessels. | Gross Tonnage. | Receipts. |
|---|---|---|---|
| | | | £ |
| 1880 | 2026 | 4,344,519 | 1,593,620 |
| 1890 | 3389 | 9,749,130 | 2,679,360 |
| 1895 | 3434 | 11,833,637 | 3,124,149 |
| 1896 | 3409 | 12,039,859 | 3,182,800 |
| 1897 | 2986 | 11,123,403 | 2,913,222 |
| 1898 | 3503 | 12,962,632 | 3,411,791 |
| 1899 | 3607 | 13,815,992 | 3,652,751 |

The number of passengers who went through the Canal in 1899 was 221,347 as against 219,671 in 1898, and 191,224 in 1897.

*Canals.*—The canals, being designed specially for perennial or flood irrigation, are only partially used for communication, since the Nile serves for this purpose through the country. In the Delta, however, the large canals, Raya Behera, Raya Menufieh, Bahr Shebin, Mahmudieh Canal, Raya Tewfiqieh, and the Ismailieh Canal, are largely used to reach parts of the Delta which would otherwise be far from water transport.

*Roads.*—Until quite recently there were no roads laid out and maintained as such, except in the immediate neighbourhood of the large towns, and the only communication was by the footpaths across the cultivation. Now, however, agricultural roads are being constructed in most of the provinces, and 1268 miles are open, 324 miles having been constructed in Upper Egypt, and 944 in Lower Egypt, up to the end of 1899.

*Railways.*—On 1st January 1901 there were in Egypt 1393 miles of railways belonging to and worked by the State, and 670 miles of light agricultural railways belonging to private companies (see below): in all, 2063 miles; 1403 miles being in the Delta, and 660 miles in Upper Egypt, exclusive of the military railway in the Sudan.

The following table shows since 1880 the length of line of the State railways, the number of passengers and the weight of goods carried, and the net receipts :—

| Year. | Line. | Number of Passengers. | Goods carried. | Net Receipts. |
|---|---|---|---|---|
| | Miles. | | Tons. | £E. |
| 1880 | 944 | 3,086,478 | 1,143,312 | 750,134 |
| 1890 | 961 | 4,696,286 | 1,721,492 | 798,418 |
| 1895 | 1098 | 9,518,000 | 2,398,000 | 994,000 |
| 1896 | 1143 | 9,854,000 | 2,498,000 | 1,033,000 |
| 1897 | 1166 | 10,742,546 | 2,796,096 | 1,123,360 |
| 1898 | 1214 | 11,312,400 | 2,786,780 | 1,114,033 |
| 1899 | 1393 | 11,284,284 | 3,055,897 | 1,161,636 |

Of late years lines of light agricultural railways have been opened by private companies in the Delta and in the Fayum. In connexion with these lines there are 164 miles of telegraphs and 310 miles of telephones.

*Telegraphs and Posts.*—The telegraphs belonging to the Egyptian Government were, at the end of 1900, of a total length of 2106 miles, the length of the wire being 9440 miles. The Government have given concessions to a telephone company for urban telephone lines. The Eastern Telegraph Company, also by concessions, have telegraph lines across Egypt from Alexandria *viâ* Cairo to Suez, and from Port Said to Suez, connecting their cables to England and India. Number of telegrams, 2,994,332 in 1899, not including telegrams sent by the Eastern Telegraph Company. Receipts, £E.54,448 ; expenditure, £E.44,000. In 1900 the number of telegrams was 3,288,662.

There are 313 post offices in the towns of Egypt, 160 travelling offices, and 414 localities where the rural post has been established. The Egyptian Post Office now transacts all the services which exist in the post offices of other countries forming the Postal Union.

The following table gives the number of letters, post-cards, newspapers, &c., despatched through the Egyptian Post Office in the year 1898 :—

| | Inland. | Abroad. | Total. |
|---|---|---|---|
| Letters and post-cards | 12,260,000 | 2,473,000 | 14,733,000 |
| Newspapers | 7,100,000 | 940,000 | 8,040,000 |
| Parcels | 274,000 | 289,800 | 563,800 |
| Total | 19,634,000 | 3,702,800 | 23,336,800 |

In 1899 these totals had arisen to: inland, 20,758,000 ; abroad, 3,903,700 ; total, 24,661,700. Receipts (1899), £E.129,874 ; expenditure, £E.108,198.

Post-office orders and remittances through the post office (1898) numbered 563,800, and amounted to the value of £E.16,437,000 ; in 1899, post-office orders and remittances numbered 598,500, and amounted to a value of £E.17,437,000.

Thirty per cent. of the total foreign correspondence was with Great Britain.

*Money.*—Egyptian money is minted at the Berlin Mint. The nominal value of the coinage (including re-coinage) from 1887 to 1900 was :—

| Years. | Gold. | Silver. | Nickel. | Bronze. | Total. |
|---|---|---|---|---|---|
| | Piastres. | Piastres. | Piastres. | Piastres. | Piastres |
| 1887–1900 | 5,202,400 | 190,584,769 | 22,080,289 | 611,779 | 218,479,237 |

## FINANCE.

The history of Egyptian finance is the story of Egypt since 1863, the date of the accession of the Khedive Ismaïl.

***History, 1863-1876.*** The notorious and unparalleled extravagance of that ruler necessitated continual recourse on increasingly onerous terms to the capitalists of Europe, and finally plunged his country into a sea of political and financial embarrassment from which it is only now emerging. When Ismaïl came to the throne the Egyptian debt amounted to a little over three millions. By the end of 1876 it was already estimated at ninety-one millions, and in reality considerably exceeded this figure. During the same period the taxation of the land, the principal source of revenue, had been increased about 50 per cent. Under the improvident system of borrowing pursued by Ismaïl, the amount of debt contracted very considerably exceeded the money actually realized, and even of the latter very little was expended on developing the resources of the country. It is stated in Mr Cave's report of March 1876, that "for the present large amount of indebtedness there is absolutely nothing to show but the Suez Canal, the whole proceeds of the loans and floating debt having been absorbed in payment of interest and sinking funds, with the exception of the sum debited to that great work." The Suez Canal, from which, owing to the forced sale of the country's interests therein, Egypt derives no direct benefit to-day, cost the Egyptian Government sixteen millions.

***1876-1882.*** By the end of 1875 this wild career of prodigality had begun to produce its natural result of serious financial embarrassment. In May of that year, in order to allay the apprehensions of the foreign creditors of Egypt, and to put a curb on the extravagant borrowing of Ismaïl, the Caisse de la Dette was instituted. The Caisse was at first composed of only three members, a Frenchman, an Austrian, and an Italian, but in the following year an Englishman was added. The original functions of the members were to act as the receivers of certain revenues that had been assigned to the service of the debt. In order to render their powers effective, they were given the right to sue the Government in the Mixed Courts for any breach of engagement towards the bondholders. The effects of this measure were far more momentous than was apparent at the time or than was intended by its authors. It was, in fact, the beginning of international interference in the financial administration of Egypt. From this moment the period of financial reform may be said to have commenced. Shortly afterwards, in November of the same year, a general settlement of the liabilities of the country was effected on the proposals of Mr Goschen and M. Joubert. It was recognized that no mere rearrangement of existing liabilities could be expected to produce satisfactory results unless some guarantees were given against future maladministration. For this purpose the Dual Control was instituted. In its first form it consisted of two controllers, an Englishman and a Frenchman, the former superintending the revenue and the latter the expenditure of the country. This arrangement was of short duration. It was based upon erroneous information supplied by the Khedive and his ministers as to the real resources of the country. It was only with the greatest possible difficulty, and by the application of the most rigorous and most arbitrary measures to the unfortunate Egyptian taxpayer, that the payment of the coupon could be continued. Finally, in the hope of obtaining a reduction of the rate of interest on the debt, Ismaïl consented, in January 1878, to the appointment of a commission armed with full powers to inquire into the whole state of the country. The first report of this commission insisted on the necessity of a proper system of government through responsible ministers before any real reform could be effected. This was at first accepted by the Khedive, and in the new cabinet the two European controllers were changed into responsible ministers entrusted respectively with the portfolios of the ministries of Public Works and Finance. The new order soon became irksome to the autocratic spirit of Ismaïl. The dismissal of the ministry, followed by the opposition of the Khedive to the later measures recommended by the commission of inquiry, culminated in his deposition in June 1879. Through the joint action of the British and French Governments, the Dual Control was re-established in a different form, with increased powers. The two controllers took part in the deliberations of the council of ministers, and worked together in their supervision of the financial administration, the principle of dividing their functions being abandoned.

These changes enabled the financial proposals of the commission of inquiry to be put into execution, and shortly after the accession of Tewfik they were embodied in the law of liquidation of July 1880, the next general settlement of the liabilities of Egypt. By this law the floating debt was paid off and the debt consolidated into a few large loans, the rate of interest being reduced to what it was at the time considered just possible for the country to pay. Under this settlement the Egyptian debt was composed as follows:—

| | |
|---|---|
| Privileged debt | £22,609,000 [1] |
| Unified debt | 58,018,000 |
| Daïra loan | 9,513,000 |
| Domains loan | 8,500,000 |
| | £98,640,000 |

The rate of interest was fixed at 5 per cent. on the privileged and Domains loans, and 4 per cent. on the unified and Daïra loans, the latter being entitled to an additional 1 per cent. contingent on certain circumstances that have never arisen. The total annual encumbrances of the country, including the tribute due to Turkey and the interest on the Suez Canal shares bought by Great Britain, but excluding the interest on the Daïra and Domains loans—which were expected to be defrayed by the revenues of the respective estates on which these loans were secured—amounted to four and a half million pounds, about half the then annual revenue of Egypt. Further, the revenue was divided between the Government and the bondholders, any surplus in the latter's share after full

[1] The figures of the Egyptian debt are always given in pounds sterling.

payment of the interest being devoted to redemption of the capital. A brief period of prosperity followed the passing of the law of liquidation, but the Arabist rebellion and the events which culminated in the British occupation of Egypt in September 1882, immediately followed by the disastrous reverses in the Sudan, again plunged the country into financial embarrassment. A new loan was absolutely necessary to settle the Alexandria indemnities and to pay off the liabilities arising out of the rebellion and the Sudan war. Moreover, the proportion of the revenue assigned to the Government by the law of liquidation was altogether insufficient for the expenses of administration, so that while the sinking fund was in full operation, the Treasury was compelled to borrow on short loans at high rates of interest in order to meet its ordinary expenditure. At the initiative of the British Government, negotiations were begun with the Great Powers and Turkey, which, after prolonged discussions, resulted in the London convention of March 1885. That convention was the last settlement of the liabilities of Egypt, and, with a few subsequent modifications of detail, its dispositions form the organic law under which Egyptian finance is administered at the present day.

*British control.*

It will be convenient here to state, as briefly as possible, the exact position of the Egyptian Government in respect of its financial autonomy, as established by the various treaties, conventions, and agreements in force. By the Imperial firman of June 1873, the Khedive of Egypt obtained, subject to the payment of an annual tribute to Turkey of £696,000, complete fiscal autonomy, including the right to conclude commercial conventions and to raise loans. The latter privilege was taken away by the firman appointing Tewfik Pasha, and since that time Egypt cannot raise a loan without the previous consent of the Sultan. The international obligations of Turkey remained, of course, binding upon Egypt, and amongst them the capitulations, by which certain privileges are conferred upon foreigners resident in the Ottoman dominions. From a financial point of view the most important of these privileges—based to a certain extent on the text of the original treaties, but still more on an abusive extension in practice which had grown up in Egypt—is immunity from all direct taxation without the assent of their respective governments. The only exception, resulting from the Ottoman law under which foreigners are allowed to acquire and hold real property, is in the case of the land-tax. At the present time all taxes that were formerly paid by natives and not by foreigners have been abolished in Egypt, but the immunity described above constitutes a most serious obstacle to all schemes for redistributing the burden of taxation in a more equitable manner. The supervision exercised over the finances of Egypt by the French and British controllers prior to the British occupation was abolished in 1883, and replaced by that of a British official called the Financial Adviser. This functionary is appointed by the Khedive on the recommendation of the British Government, and has a seat on the council of ministers, but without a vote. It has been laid down by the British Government that "no financial decision should be taken without his consent," an interpretation which has never been questioned by the Egyptian Government. In addition to the control of the Financial Adviser, there exist in Egypt certain commissions or boards, known as "Mixed Administrations," appointed in virtue of international agreements, and having relations of a more or less ill-defined, but quasi-independent character with the Egyptian ministry of finance. First and foremost is the Caisse de la Dette, on which, since 1885, the six Great Powers—France, Austria, Italy, Great Britain, Germany, and Russia—are represented. The functions of the Caisse, originally limited to receiving certain assigned revenues on behalf of the bondholders, have since that date become much more important. The exact extent of their powers is not capable of accurate definition, nor would it be possible to lay down limits which would meet with general acceptance from all parties. The widest interpretation of their functions that has been put forward would give them the right to control, on behalf of the Powers of Europe, the due execution by the Egyptian Government of almost all the complicated international agreements regarding the finances of the country. In virtue of the law of liquidation, their assent, as well as that of the Sultan, is necessary before any new loan can be issued. No portion of the general reserve fund can be used without their sanction. All questions are decided by the vote of the majority of the members, with the exception of grants for extraordinary military expenditure, which, by an arrangement concluded with the Powers in November 1899, require unanimity. All assigned revenues are paid directly to the Caisse de la Dette by the collecting departments without passing through the Ministry of Finance. After the Caisse de la Dette come the Railway Board and the Commissions of the Daïra and Domains, each consisting of three members—an Englishman, a Frenchman, and an Egyptian. The former administers the railways, telegraphs, and port of Alexandria, paying the net receipts, after deduction of the expenses, fixed for the railways at 45 per cent. of the gross receipts, into the Caisse. The Daïra and Domains Commissions administer the large estates that are mortgaged to the holders of those loans. Out of the net profits they pay the annual interest charge, and any surplus and the produce of the sales of land are employed in paying off the capital. Should the net profits in any year be insufficient to meet the coupon, the Egyptian Government is bound to make good the difference. Since their creation both these administrations showed an annual deficit up to 1890. From that date, with the exception of the year 1895, the Daïra has yielded a surplus; but the Domains continued to be administered at a considerable loss, which formerly varied between £50,000 and £200,000 a year, down to 1900, in which year there was a surplus for the first time.

*Financial status.*

It is now possible to explain the working of the financial system prescribed by the London convention. The principle of dividing the revenues of the country between the Ministry of Finance and the Caisse de la Dette was maintained. The revenue assigned to the service of the debt remained as before, so that the security of the bondholders was in no way diminished. At the same time it was recognized that the non-assigned revenue was insufficient to meet the expenses of administration. A certain scale of administrative expenditure was, therefore, authorized, and the Caisse, after paying in full the interest on the debt, had to make good out of the balance of the assigned revenue any deficit between the authorized expenditure and the non-assigned revenue. If, after making good any such deficit, a surplus still remained, this surplus was divided equally between the Caisse and the Government, the share of the former being applied to the reduction of the debt, while the Government was free to dispose of its share as it thought best. By an arrangement with the Powers, concluded in 1888, the Caisse's half-share in the surplus is now paid into a reserve fund, and the sinking fund is suspended until that fund amounts to two millions. The authorized expenditure for administrative purposes was originally fixed at £E.5,237,000,[1] but by subsequent agreement with the Powers certain other items have been added, so that in

*Working.*

[1] The Egyptian pound = £1, 0s. 6d.

1900 it amounted to £E.6,195,000. The effective administrative expenditure has always exceeded the amount fixed by the London convention, and of late years the growing wants of a country in process of development have naturally had a tendency to increase this excess. Any excess can, however, only be met out of the half-share of the eventual surplus which is at the free disposal of the Government. Consequently, in order to meet new expenditure necessitated by the new requirements of the country, just double the amount of revenue must be raised. One-half of the new revenue increases the Government share of the surplus, and thereby pays for the new expenditure. The other half goes for the moment into the general reserve fund, and would ultimately, when that fund has attained its maximum, be employed in reducing the debt. This limitation of administrative expenditure is the great blot in the system designed by the authors of the London convention, and now that the resources of the state are greatly on the increase, it has become a serious obstacle to the development of the national prosperity. The London convention left the permanent rate of interest on the debt, as fixed by the law of liquidation, unchanged, but in order to afford temporary relief to the Egyptian exchequer, a reduction of 5 per cent. on the interest of the debt was granted for two years, on the condition that if at the end of that period payment, including the arrears of the two years, was not resumed in full, another international commission was to be appointed to examine into the whole financial situation. Lastly, the London convention empowered Egypt to raise a loan of nine millions, guaranteed by all the Powers, at a rate of interest of 3 per cent. For the service of this loan an annuity of £315,000 is provided in the Egyptian budget for interest and sinking fund. This sum was sufficient to pay the Alexandria indemnities, to wipe out the deficits of the preceding years, to give the Egyptian treasury a working balance of £E.500,000 and thereby avoid the creation of a fresh floating debt, and to provide a million for new irrigation works. To the wise foresight which, at a moment when the country was sinking beneath a weight of debt, did not hesitate to add this million for expenditure on productive works, the present prosperity of Egypt is largely due.

*1885-1899.*

During the two years that followed the London convention, the financial policy of the Egyptian Government was directed to placing the country in a position to resume full payment of the interest on the debt in 1887, and thereby to avoid the appointment of an international commission. By the exercise of the most rigid economy in all branches this end was attained, though budgetary equilibrium was only secured by a variety of financial expedients, justified by the vital importance of saving Egypt from further international interference. By such means this additional complication was averted, but the struggle to put Egypt in a genuinely solvent position was by no means over. It was not until his report on the financial results of 1888 that Sir Evelyn Baring (afterwards Lord Cromer) was able to inform the British Government that the situation was such that "it would take a series of untoward events seriously to endanger the stability of Egyptian finance and the solvency of the Egyptian Government." From this moment the corner was turned, and the era of financial prosperity commenced. The results of the labours of the preceding six years began to manifest themselves with a rapidity which surprised the most sanguine observers. The principal feature of the successive Egyptian budgets from 1890 was the fiscal relief afforded to the population. This period may be said to have been brought to a close in 1894, though a subsequent reduction of the land-tax by £E.216,000 a year was effected in 1898. From 1894 onwards it was thought desirable to pay more attention than heretofore to the legitimate demands of the spending departments. Accordingly, money was devoted to remunerative objects, such as irrigation works, railway extension, and also to others, such as the construction of hospitals, prisons, and other public buildings, the improvement of education, &c., which, although not directly remunerative, are equally necessary to the well-being of the country. In 1896 the decision of the British Government to undertake the expedition to Dongola, leading by the natural progress of events to the reconquest of the Sudan, subjected the finances of Egypt to a severer strain than had been experienced since they had been placed on a sound footing. The endeavour to obtain assistance towards the cost of the military operations from the general reserve fund, with the co-operation of the Caisse de la Dette, failed, owing to an adverse decision of the Mixed Tribunals as to the legality of such a course. Nevertheless, with a certain amount of financial aid from the British Government, the Egyptian treasury was able to meet the expenditure of the campaign without recourse to extraordinary expedients. The conduct of the war was quite as remarkable from a financial as from a military point of view, and there have been few instances in history of such great results being obtained at such comparatively small cost. The total amount expended for the whole campaign, from the commencement of the Dongola expedition to the capture of Omdurman, was in round figures two millions. Of this about £E.900,000 was spent on railway and telegraph construction, works of permanent utility, the balance of £E.1,100,000 representing the purely military expenditure. After the conclusion of the campaign a further sum of £E.300,000 was granted for the extension of the railway to Khartum. The British Government gave a grant-in-aid of £800,000, and the balance was borne by the Egyptian treasury out of its half-share in the annual surpluses. So far, then, the finances of the country triumphantly stood the test to which they were subjected. But a graver problem preoccupied the minds of those who were responsible for the financial administration of Egypt, and that was whether the resources of the country could support the annual burden of the occupation and government of so large an area without detriment to the normal development of Egypt itself. It was wisely decided to leave no room for doubt on this point, by at once taking steps to increase those resources on a large scale in the immediate future. A vast scheme for the construction of a reservoir at Assuan for the storage of the waters of the Nile had long been under consideration. In 1898 a financial arrangement was concluded whereby the execution of this project, which will enormously increase the productive powers of the country, was at once put in hand. The original estimate of the cost of the works was two millions, and the Egyptian Government arranged to meet the expenditure by the payment of an annuity of £160,000 a year for thirty years, beginning from the 1st July 1903. This important undertaking was brought to a successful termination in 1902, and the actual expenditure incurred amounted to about £E.3,250,000. The difference between the sum originally provided and the ultimate cost was granted by the Caisse de la Dette out of the general reserve fund. In the course of 1899 a great financial reform, the desirability of which had long made itself felt, was seriously taken in hand, namely, the reassessment of the land-tax. The existing assessment, which was made before the British occupation, had long been condemned by all competent authorities, but the inherent intricacies and difficulties of the problem had hitherto postponed a solution. After careful study and a preliminary examination

of the land, a scheme was passed which has given satisfaction to the land-owning community, and which will, when completed, distribute the tax equitably in proportion to the fertility of the soil.

***Results: 1883-1900.*** This brief sketch of the history of Egyptian finance would not be complete without a few statistics showing more definitely the remarkable progress made since 1883. The following particulars, giving the general financial results obtained since the commencement of the British occupation, are taken from Lord Cromer's reports and other official publications. The difference between the real ordinary revenue and expenditure of the Egyptian Government during these years is shown in the following table:—

| Year. | Surplus. | Deficit. |
|---|---|---|
| | £E | £E. |
| 1883 | ... | 921,000 |
| 1884 | ... | 460,000 |
| 1885 | ... | 733,000 |
| 1886 | ... | 492,000 |
| 1887[1] | 348,000 | ... |
| 1888 | ... | 53,000 |
| 1889 | 218,000 | .. |
| 1890 | 647,000 | . |
| 1891 | 933,000 | .. |
| 1892 | 746,000 | ... |
| 1893 | 687,000 | ... |
| 1894 | 692,000 | .. |
| 1895 | 1,003,000 | ... |
| 1896 | 1,089,000 | ... |
| 1897 | 1,383,000 | ... |
| 1898 | 1,332,000 | ... |
| 1899 | 1,270,000 | ... |
| 1900 | 1,552,000 | ... |

This table shows very clearly the cleavage line between the period of semi-insolvency and that of prosperity through which Egypt has passed. During the four years 1883–86, both inclusive, the aggregate deficit amounted to £E.2,606,000. By 1886 the Sudan expenditure had greatly diminished. The efforts of the reformers, notably those of the irrigation officers, had begun to bear fruit. The aggregate surplus of the fourteen years from 1887 to 1900, both inclusive, was £E.11,847,000. During the same period direct taxation was reduced to the extent of about £E.1,275,000 a year. Arrears of land-tax to the extent of £E.1,245,000 were remitted. In the domain of indirect taxes the salt-tax was reduced by 40 per cent., the postal and telegraph rates were reduced by 50 per cent., and the octroi duties were abolished in all the provincial towns. Large reductions were made in the railway rates. The only increase of taxation was in the tobacco duty, which has been raised from P.T. 14 to P.T. 20 per kilogramme. The house-tax was also imposed on European residents in Egypt. In spite of the great relief thus afforded to the taxpayers of Egypt, the revenue increased by £E.2,512,000. In 1883 a revenue of £E.8,935,000 was wrung with difficulty from the country. In 1900 £E.11,447,000 was collected with ease. On the other hand, a stringent control has been exercised over the expenditure. In 1883 the "ordinary" expenditure amounted to £E.9,856,000. In 1900 it amounted to £E.9,895,000, an increase of only £E.39,000.

***Fall in prices: 1885-1898.*** In connexion with this subject it must be borne in mind that, during the period under review, Egypt has suffered very severely from the general fall in prices. Had it not been for the great increase of production, the result of improvements in the system of irrigation, and the fiscal relief afforded to the landowners, the agricultural depression would, without doubt, have seriously impaired the financial situation. Cotton and sugar are the two principal products of the country, forming together about 90 per cent. of the total value of the exports. The following tables show the amount and value of the cotton and sugar crops from 1885 to 1898:—

*Cotton.*

| Season. | Cantars of 50 Kilos. | Price per Cantar. | Value. |
|---|---|---|---|
| | | P.T.[1] | £E. |
| 1885–86 | 2,905,000 | 228 | 6,625,000 |
| 1886–87 | 3,026,000 | 240 | 7,262,000 |
| 1887–88 | 2,963,000 | 249 | 7,382,000 |
| 1888–89 | 2,766,000 | 264 | 7,310,000 |
| 1889–90 | 2,872,000 | 294 | 8,455,000 |
| 1890–91 | 3,638,000 | 255 | 9,281,000 |
| 1891–92 | 4,195,000 | 205 | 8,594,000 |
| 1892–93 | 4,610,000 | 206 | 9,510,000 |
| 1893–94 | 4,548,000 | 191 | 8,707,000 |
| 1894–95 | 4,347,000 | 168 | 7,326,000 |
| 1895–96 | 4,695,000 | 220 | 10,342,000 |
| 1896–97 | 5,177,000 | 195 | 10,089,000 |

*Trade and Commerce, 1884–98.*—The following table shows the average annual value of the total imports and exports, excluding bullion, for the three quinquennial periods between 1884 and 1898:—

| Period. | Imports. | Exports. | Total Trade. |
|---|---|---|---|
| | £E. | £E. | £E. |
| 1884–88 | 8,257,000 | 11,106,000 | 19,363,000 |
| 1889–93 | 8,423,000 | 12,887,000 | 21,310,000 |
| 1894–98 | 9,822,000 | 12,592,000 | 22,414,000 |

Owing to the great perturbation of prices that has characterized the period under review, the above figures give a very imperfect impression of the real growth of the trade of the country. A clearer view is obtained by comparing the quantities of some of the

[1] Owing to a change in the way of making up the accounts, normal expenditure of £E.340,000 was not included in the accounts of 1887, so that there was practically financial equilibrium in that year.

[1] 100 P.T. = £E.1 = £1, 0s. 6d.

[2] An ardeb of cotton seed weighs 267 lb.

more important categories of imports and exports. In the following tables those articles have been selected which have an intimate connexion with the national prosperity :—

*Average Annual Imports.*

| Period | Cotton Goods. | Steel and Iron Goods. | Building Wood | Coal. |
|---|---|---|---|---|
| | Kilos. | Tons. | £E. | Tons. |
| 1884–88 | 13,452,000 | 12,000 | 308,000 | 449,000 |
| 1889–93 | 13,665,000 | 25,000 | 388,000 | 513,000 |
| 1894–98 | 16,984,000 | 34,000 | 513,000 | 701,000 |

|---|---|---|---|---|
| | Kantars. | Hectolitres. | Kilos. | Kantars. |
| 1884–88 | 2,707,000 | 4,240,000 | 38,919,000 | 226,000 |
| 1889–93 | 3,659,000 | 5,425,000 | 43,375,000 | 656,000 |
| 1894–98 | 4,951,000 | 6,458,000 | 63,147,000 | 1,083,000 |

**Debt.** On the 31st December 1900 the total amount of the Egyptian debt was £102,714,000, of which £7,273,000 was held by the commissioners of the debt on account of the general reserve fund and the fund of the economies of the conversion, as will be explained hereafter, thus leaving £95,441,000 in the hands of the public. The particulars of the different loans are shown in the accompanying table :—

| | On the Market. | Held by the Caisse de la Dette. | Total. |
|---|---|---|---|
| | £ | £ | £ |
| Guaranteed loan 3 per cent. | 8,333,000 | 392,000 | 7,941,000 |
| Preference debt 3½ per cent. | 29,393,000 | 1,055,000 | 28,338,000 |
| Unified debt 4 per cent. | 55,972,000 | 5,493,000 | 50,479,000 |
| Domains loan 4¼ per cent. | 2,899,000 | 2,000 | 2,897,000 |
| Daïra Sanieh loan 4 per cent. | 6,117,000 | 331,000 | 5,786,000 |
| Total | 102,714,000 | 7,273,000 | 95,441,000 |

In June 1890 the assent of the Powers was obtained to the conversion of the preference, Domains, and Daïra loans on the following conditions, imposed at the initiative of the French Government :—

1. The employment of the economies resulting from the conversion was to be the subject of future agreement with the Powers.
2. The Daïra loan was to be reimbursed at 85 per cent., instead of 80 per cent., as provided by the law of liquidation.
3. The sales of Domains and Daïra lands were to be restricted to £E.300,000 a year each, thus prolonging the period of liquidation of those estates.

The interest on the preference stock was reduced from 5 to 3½ per cent., and on the Domains from 5 to 4¼ per cent. As regards the Daïra loan, there was no apparent reduction in the rate of interest, which remained at 4 per cent., but the bondholders received £85 of the new stock for every £100 of the old. The annual economy to the Egyptian Government amounted at the time of the conversion to £E.348,000. Further, an engagement was entered into that there should be no reimbursement of the loans till 1905 for the preference and Daïra, and 1908 for the Domains. By an arrangement concluded in June 1898, between the Egyptian Government and a syndicate, the unsold balance of the Daïra estates will be taken over by the syndicate in October 1905, for the amount of the debt remaining. The Daïra loan will then cease to exist.

The total amount of Egyptian bonds on the market on the 1st January 1883 and 1st January 1901 respectively was as follows :—

| | |
|---|---|
| 1st January 1883 | £96,457,000 |
| 1st January 1901 | 95,441,000 |
| Showing a reduction of | £1,016,000 |

During this period fresh debt was incurred for the following purposes :—

| | |
|---|---|
| Alexandria indemnities | £4,250,000 |
| Deficits of years prior to 1886, including Sudan | 4,030,000 |
| Commutations of pensions and allowances of the Khedivial family | 2,769,000 |
| Treasury working balance | 513,000 |
| Irrigation works | 1,959,000 |
| Expenses of loans (commissions, &c.) | 1,169,000 |
| | £14,690,000 |
| *Less*—Paid out of special receipts (sales of land, &c.) | 1,305,000 |
| Leaving a net increase on this account of | £13,385,000 |
| To this sum must be added the amount by which the debt was increased in consequence of the conversion of the preference and Daïra stocks | 1,945,000 |
| Making a total increase of | £15,330,000 |

On the other hand, the amount of bonds on the market has been diminished by the following amounts :—

| | | |
|---|---|---|
| By sales of property (mostly Daïra and Domains) | £6,304,000 | |
| By surplus revenue, of which £7,273,000 is now held by the commissioners of the debt | 10,042,000 | |
| | | £16,346,000 |
| Making a net reduction of | | £1,016,000 |

These figures are remarkable. They show that in spite of about £13,000,000 having been borrowed for various objects, and in spite of conversion operations, which added nearly £2,000,000 to the capital of the debt, the total amount of Egyptian bonds on the market in 1901 was one million less than in 1883. This result was mainly, although not entirely, due to the system under which large sums of money remained at the close of each year in the hands of the commissioners of the debt, and were by them invested in Egyptian stocks. Whatever objections may on other grounds be urged against this system, it cannot be doubted that its result is to accumulate what is practically a large and ever-increasing sinking fund. During the five years 1896–1900 debt was either paid off or withdrawn from the market by Government purchase at an average rate of no less than £1,262,000 a year. It should be added that the interest charge on the bonds on the market, which on the 1st January 1883 stood at £4,166,000, was in 1901 £3,604,000, a diminution of £562,000.

**Reserve Funds.** In order to give a complete account of the financial position of the Egyptian Government, some explanation must be supplied of the various reserve funds which are in operation. The general reserve fund was created with the assent of the Powers by the decree of the 12th July 1888. Beginning with a sum of £E.340,000, being the amount saved by a change in the system of accounts introduced in 1887, this fund is increased annually by the share of the Caisse in the surplus, by the interest on the invested accumulations, and by the produce of the sale of certain Government lands. When the unpledged portion of the fund reaches the sum of £E.2,000,000, no further accumulation is allowed under the provisions of the above-mentioned decree, and the excess has to be applied to sinking fund. Up to the end of 1901 this contingency had never occurred. The fund is primarily intended to be used in making good any deficiency in the payment of the interest on the debt or of the administrative expenditure authorized by the London convention and subsequent agreements. It may also be drawn upon for extraordinary expenditure with the previous consent of the commissioners of the Caisse. The total amount paid into the general reserve fund, from its constitution in 1888 down to the end of 1900, was £E.8,106,000, of which £E.4,577,000 was actually spent on extraordinary expenditure, and a further sum of

£E.2,342,000 was pledged for the execution of various works in course of progress, leaving an unpledged balance of £E.1,187,000. Out of the total amount advanced, £E.2,305,000 was granted for drainage and irrigation works, £E.2,669,000 for improving the state railways, £E.1,113,000 for the construction of public buildings, &c., and £E.647,000 for the relief of taxation. The unemployed balance of the fund, including the portion that is pledged but has not yet been actually advanced, is invested in Egyptian stocks. The special reserve fund was constituted in 1886, and is chiefly made up out of the net savings of the Government on its share of the annual surpluses. This fund is at the absolute disposal of the Egyptian Government. Since its creation the total receipts have amounted to £E.4,815,000. At the end of 1900 extraordinary expenditure to the amount of £E.4,006,000 had been charged to this fund, leaving an apparent balance of £E.809,000. As, however, further expenditure amounting to £E.50,000 had been authorized, although not actually incurred, when the accounts of 1900 were closed, the real state of the fund was a surplus of £E.759,000. The whole of the extraordinary expenditure of the Sudan campaign, with the exception of the amount granted on this account by the British Government, was charged to the special reserve fund, amounting, in round figures, to £E.1,500,000. The principal remaining items that have been debited to this fund are £E.758,000 for commutation of pensions and £E.350,000 for reproductive works.

*Conversion economies.*

A third fund is formed by the accumulation of the economies resulting from the conversion of the privileged, Domains, and Daira loans in 1890. As already explained, this fund cannot be employed without the assent of the Powers. Up to the end of 1899 none of the numerous proposals submitted by Egypt had proved acceptable to the French Government. In the meantime, the annual economies, amounting, in 1900, to £E.307,000, together with the interest on the accumulations of the past, were invested in Egyptian stocks by the Caisse de la Dette, and on the 31st December 1900 the value of the fund amounted to £E.4,002,000. This system virtually acts as a sinking fund, but one of a very expensive nature for the Egyptian Government, inasmuch as bonds which the Government have the legal right to pay off at par are purchased at the market price, which is, and appears likely to remain, considerably above par. While on this branch of the subject it may be of interest to refer to a passage in Lord Cromer's annual report for 1898, in which, after giving an approximate estimate of the annual charges unnecessarily borne by Egypt, he concludes by stating that, "broadly speaking, it is no exaggeration to say that internationalism imposes an extra charge of about £1,750,000 a year on the Egyptian treasury."

*Egyptian Budget.*

In conclusion, it may be useful to give a brief analysis of the latest published accounts, namely, those for 1900. The total revenue amounts to £E.11,663,000, in which figure is included an annual contribution of £E.216,000 from the general reserve fund, the result of an arrangement with the Powers to make good to the Government a reduction of the land-tax to that amount. This item is therefore not real revenue, but a mere transfer. Of the above revenue £E.7,339,000 was assigned to the service of the debt and was paid into the Caisse de la Dette, and the balance, £E.4,324,000, was received directly by the Government treasury. The service of the debt, including the economies of the conversion of the preference stock, amounted to £E.3,614,000, which figure is exclusive of a sum of £E.181,000 charged to the administrative budget on account of the debt, and the administrative expenditure, as authorized by the London convention and subsequent arrangements, to £E.6,195,000. There remained, therefore, a sum of £E.1,854,000 to be divided between the Government and the general reserve fund. In virtue of certain agreements made with the Powers, the share of the Government, originally fixed at one-half by the London convention, is increased by £E.45,000, and therefore amounted to £E.972,000. From this must be deducted the difference between the real and the authorized expenditure, namely, £E.413,000, so that the real surplus at the disposal of the Egyptian Government was £E.559,000. On the other hand, the amount received by the general reserve fund must be reduced by the contribution of £E.216,000 to the ordinary revenue to which allusion has already been made. The actual amount paid into the general reserve fund was, therefore, £E.666,000 (the half-share £E.927,000 – £E.45,000 – £E.216,000). To sum up in an intelligible manner the results of this complicated system, the real surplus revenue of the country amounted to £E.1,552,000, of which £E.559,000 belongs to the Egyptian Government, £E.666,000 increases the general reserve fund, £E.265,000, representing the economies of the conversion of the preference stock, is paid into the economies fund, and £E.62,000 is devoted to sinking fund.

The chief item of revenue is the land-tax, which brought in £E.4,367,000. The cultivated area paying taxes amounts to 5,541,000 feddans,[1] so that the average tax per feddan is 788 milliemes (= 15s. 4d.). The customs (including the duty on tobacco) produced £E.2,418,000, and the railways £E.2,159,000. These three heads of revenue account for £E.8,944,000, equal to 77 per cent. of the total receipts. The actual revenue collected amounted to £E.11,447,000, of which a certain proportion consists of receipts from administrations rendering direct service to the public, such as the railways, telegraphs, post office, &c. The net receipts from these latter services do not yield more than a normal return on the capital that has been expended on them. Deducting these and certain other items of revenue, which are also not taxation properly so called, such as rents from state property, the total amount paid by the Egyptian taxpayer works out to £E.8,502,000, or 813 milliemes (= 15s. 10d.) per head of the population, as compared with £E.1·014 (= £1, 0s. 9d.) in 1883.

The total expenditure in 1900 was £E.11,104,000. Under the existing system of accounts, first introduced in 1896, this figure includes (1) a sum of £E.265,000, being the annual economy resulting from the conversion of the preference debt; (2) a sum of £E.62,000 paid into sinking fund; and (3) a sum of £E.882,000, being the amount paid to the general reserve fund. As already explained, £E.216,000 of the latter sum is repaid to the Government on account of the reduction of the land-tax. The balance of £E.9,895,000 represents the effective expenditure of the year. The details of this expenditure may be summarized as follows:—

| | |
|---|---|
| 1. Charges on account of the tribute and the debt | £E.4,340,000 |
| 2. Expenditure on railways, telegraphs, post office, and other revenue-paying departments | 1,295,000 |
| 3. Khedivial civil list and allowances to the Khedivial family | 258,000 |
| 4. Administration | 2,228,000 |
| 5. Army (including the expenses of the army of occupation) | 807,000 |
| 6. Pensions | 433,000 |
| 7. Suppression of the corvée | 400,000 |
| 8. Sudan deficit | 134,000 |
| Total | 9,895,000 |

[1] The feddan is practically equivalent to the English acre.

As regards the last item, it should be observed that the total cost of the civil administration of the Sudan in 1900 was £E.332,000. The revenue amounted to £E.157,000, leaving a deficit of £E.175,000, which was borne by the Egyptian Treasury. Of this sum £E.134,000 (representing the amount provided in the budget on this account) was included in the ordinary expenditure of the Egyptian Government for 1900, and the balance of £E.41,000 was advanced out of the special reserve fund. The Sudan budget is also charged with a certain proportion of the army expenditure, amounting in 1900 to £E.283,000. This represents the additional expenditure due to the reoccupation of the Sudan. The real cost of the Sudan to Egypt in 1900 was therefore £E.458,000.

*Currency.*

The monetary system in force in Egypt dates from 1885, when through the efforts of Sir Edgar Vincent the currency was placed on a sound footing. Before that time the multiplicity of foreign silver coinage that circulated throughout the country caused grave inconvenience in all commercial transactions. The present system is based on the single gold standard, silver, nickel, and bronze being used for the subsidiary coinage. The unit is the Egyptian pound, which is divided into 100 piastres, the piastre being again divided into 10 milliemes. The Egyptian pound weighs 8·500 grammes, and contains 875 parts out of 1000 of fine gold. Its approximate value in English currency is £1, 0s. 6d. The subsidiary coinage consists of pieces of 20, 10, 5, 2, and 1 piastres in silver; 5, 2, and 1 milliemes in nickel; and ½ and ¼ millieme in bronze. These coins are token coins, their intrinsic value being considerably less than their nominal value. The amount in circulation is controlled by the Ministry of Finance, and the coins are changed into gold on demand at the Government treasury. They are only legal tender up to 200 piastres. The history of the currency reform in Egypt is interesting as affording a practical example of a system which has been much discussed in connexion with the currency question in India, namely, a gold standard without a gold coinage. The Egyptian pound is practically non-existent, nearly all that were coined having been withdrawn from circulation. Their place has been taken by foreign gold, principally the English sovereign, which circulates at a value of 97½ piastres. In practice the system works perfectly smooth, the gold flowing in and out of the country through the agency of private banking establishments in proportion to the requirements of the circulation. It is, moreover, very economical for the Government. As in most agricultural countries, there is a great expansion of the circulation in the autumn and winter months in order to move the crops, followed by a long period of contracted circulation throughout the rest of the year. Under the above system, the fluctuating requirements of the currency are met without the expense of alternately minting and melting down. Recently paper money has been introduced into the country, this privilege having been conceded by the Government to the National Bank. The notes are of the following values:—£E.100, £E.50, £E.10, £E.5, £E.1, and 50 piastres—and are payable in gold on demand. The issue department is kept wholly distinct from the general business of the Bank. An amount not exceeding one-half of the value of the notes in circulation may be invested in Egyptian stocks, and the balance of the reserve must always be held in gold. The notes are not legal tender, but are accepted by the Government in payment of taxes. Sufficient time has not yet elapsed to state whether this form of currency will become popular among the native population.

(J. L. G.)

## ARMY.

The fellah soldier may be aptly likened to a bicycle, which although incapable of standing up alone, is very useful while under the control of a skilful master. As is the soldier, so is the army. It is generally believed that the successes gained in the time of the Pharaohs were due to foreign legions; and from Cambyses to Alexander, from the Ptolemies to Antony (Cleopatra), from Augustus in the 7th century throughout the Arab period, and from Saladin's dynasty down to the middle of the 13th century, the military power of Egypt was dependent on mercenaries. The Mamelukes (slaves), imported from the eastern borders of the Black Sea and then trained as soldiers, usurped the government of Egypt, and held it till 1507, when the Ottomans began to rule. This form of government, speaking generally, endured till the French invasion at the end of the 18th century. British and Turkish troops drove the French out after an occupation of two years, the British troops remaining till 1803. Then Mehemet Ali, a small tobacconist of Kavala, Macedonia, coming with Albanian mercenaries, made himself governor, and later (1811), by massacring the Mamelukes, became the actual master of the country, and after seven years' war brought Arabia under Egypt's rule. He subdued Nubia and Sennar in 1820–22; and then, requiring a larger army, he obtained instructors from France. To them were handed over 1000 Turks and Circassians to be trained as officers, who later took command of 30,000 Sudanese. These died so rapidly in Egypt from pneumonia[1] that Mehemet Ali conscripted over 250,000 fellaheen, and in so arbitrary a fashion that many peasants mutilated themselves to avoid the much-dreaded service. The common practice was to place a small piece of nitrate of silver into the eye, which was then kept tightly bandaged till the sight was destroyed. Battalions were then formed of one-eyed men, and of soldiers who, having cut off their right-hand fingers, were made to shoot from the left shoulder. Every man who could not purchase exemption, with the exception of those living in Cairo, Alexandria, and Suez, on becoming 19 years old was liable nominally to 12 years' service; but many men were kept for 30 or 40 years, in spite of constant appeals. Nevertheless the experiment succeeded. The docile, yet robust and hardy peasants, under their foreign leaders, gained an unbroken series of successes in the first Syrian War; and after the bloody battle of Konia (1832), where the raw Turkish army was routed and the Grand Vizier taken prisoner, it was only European intervention which prevented the Egyptian General, Ibrahim Pasha, from marching unopposed to the Bosphorus. The defeat of the Turkish army at Nezib, in the second Syrian War (1839), showed that it was possible to obtain favourable military results with Egyptians when stiffened by foreigners and well commanded. Ibrahim, the hero of Konia, declared, however, that no native Egyptian ought to rise higher than the rank of sergeant; and in the Syrian campaigns nearly all the officers were Turks or Circassians, as were many of the non-commissioned officers. In the cavalry and artillery many of the privates were foreigners, numbers of the Janissaries who escaped the massacre at Stambul (1832) having joined Mehemet Ali's army.

*Early history.*

In the reign of Abbas, who succeeded Mehemet Ali, the Egyptian troops were driven from Nejd, and the Wahabi State recovered its independence. The next Khedive, Said,

[1] Similar mortality, though on a smaller scale, recurred in 1889, when Sudanese battalions coming from Suakin were detained temporarily in Cairo.

began as an ardent soldier, but took to agriculture, and at his death (1863) 3000 men only were retained under arms. Ismail, the next Khedive, immediately added 27,000 men, and in seven years was able to put 100,000 men, well equipped, in the field. He sent 10,000 men to help suppress a rebellion in Crete, and conquered the greater part of the (Nile) Sudan; but an expedition of 11,000 men, sent to Abyssinia under Prince Hassan and Rateb Pasha, well equipped with guns and all essentials, was, in two successive disasters (1875 and 1876), practically destroyed. The education of Egyptians in Continental cities had not produced the class of leaders who led the fellaheen to victory at Konia.

Ismail's exactions from the peasantry in 1880–81 reacted on the army, causing discontent; and when he was tottering on the throne he instigated military demonstrations against his own Government, and, by thus sapping the foundations of discipline, assisted Arabi's revolution; the result was the battle of Tel-el-Kebir, the British occupation, and the disbandment of the army, which at that time in Egypt Proper consisted of 18,000 men. Ismail had 500 field-guns, 200 Armstrong cannon, and factories of warlike and other stores. These latter were conducted extravagantly and badly administered.

In January 1883, Major-General Sir Evelyn Wood, V.C., was given £200,000, and directed to spend it in raising a fellaheen force of 6000 men for the defence of Egypt. He was assisted at first by 26 officers, amongst whom were two who later became successively Sirdars—Colonel F. Grenfell, commanding a brigade, and Lieutenant H. Kitchener, R.E., second in command of the cavalry regiment. There were four batteries, eight battalions, and a camel company. Each battalion of the 1st Infantry Brigade had three British mounted officers, Turks and Egyptians holding the corresponding positions in the battalions of the 2nd Brigade. The Sirdar selected these native officers from those of Arabi's followers who had been the least prominent in the recent mutiny; non-commissioned officers who had been drill-instructors in the old army were recalled temporarily, but all the privates were conscripted from their villages. The earlier merciless practice had been in theory abolished by a decree based on the German system, published in 1880; but owing to defective organization, and internal disturbances induced by Khedive Ismail's follies, the law had not been applied, and the 6000 recruits collected at Cairo in January 1883 represented the biggest and strongest peasants who could not purchase exemption by bribing the officials concerned. The difficulties experienced in applying the 1880 decree were great, but the perseverance of British officers gave the oppressed peasants, in 1885, an equitable law, since improved and altered by the Decree of 1900. Financial requirements have in more recent years caused the Sirdar to allow exemption by paying (Badalia) £20 before ballot. The Recruiting Superintending Committee, travelling through districts, supervise every ballot, and work under stringent rules which render systematic bribery difficult. The recruits who draw unlucky numbers at 19 years of age are seldom called up till they are 23, when they are summoned by name and escorted by a policeman to Cairo. To prevent substitution on the journey each recruit wears a string girdle sealed in lead. The periods of service are: with the colours, 5 years; in the reserve, 5 years, during which time they may be called up for police service, manœuvres, &c. The pay is 30 piastres (one piastre being worth 2½d.) per month for all services, and the liberal scale of rations of meat, bread, and rice remained as before in theory, but in practice the value of pay and food received was greatly enhanced. So also with the pension and promotion regulations. They were sufficiently liberal on paper, but had never been carried into effect.

*Reorganization.*

The efforts of 48 American officers, who under General Stone zealously served Ismail, had entirely failed to overcome Egyptian venality and intrigue; and in spite of the military schools, with a comprehensive syllabus, the only perceptible difference between the Egyptian officer and private in 1879 consisted, according to one of the Americans, in the fact that the first was the product of the harem, and the second of the field. Marshal Marmont, writing in 1839, mentions the capacity of the Egyptians for endurance; and it was tested in 1883, especially in the 2nd Brigade, since its officers (Turks and Egyptians), anxious to excel as drill-masters, worked their men not only from morn till eve, but also by lamplight in the corridors of the barracks. On the 31st March 1883, ten weeks after the arrival of the first draft of recruits, about 5600 men went through the ceremonial parade movements as practised by the British Guards in Hyde Park, with unusual precision. The British officers had acquired the words of command in Turkish, as used in the old army, an attempt to substitute Egyptian words having failed owing to lack of crisp, sharp-sounding words. As the Egyptian brigadier, who had spent some years in Berlin, spoke German fluently, and it was also understood by the senior British officers, that language was used for all commands given by the Sirdar on that special parade. The British drill-book, minus about one-third of the least serviceable movements, was translated by an English officer, and by 1900 every necessary British official book had been published in English and Arabic, except the new Recruiting Law (1885) and a manufacturing manual, for which French and Arabic editions are in use. The discipline of the old army had been regulated by a translation of part of the Code Napoleon, which was inadequate for an Eastern army, and the Sirdar replaced it by the Army Act of 1881, slightly modified and printed in Arabic.

The task undertaken by the small body of British officers was difficult. There was not one point in the former administration of the army acceptable to English gentlemen. That there had been no adequate auxiliary departments, without which an army cannot move or be efficient, was comparatively a minor difficulty. To succeed, it was essential that the fellah should be taught that discipline might be strict without being oppressive, that pay and rations would be fairly distributed, that brutal usage by superiors would be checked, that complaints would be thoroughly investigated, and impartial justice meted out to soldiers of all ranks. An epidemic of cholera in the summer of 1883 gave the British officers their first chance of acquiring the esteem and confidence of their men, and the opportunity was nobly utilized. While the patient fellah, resigned to the decrees of the Almighty, saw the ruling Egyptian class hurry away from Cairo, he saw also those of his comrades who were stricken tenderly nursed, soothed in death's struggles, and in many cases actually washed, laid out, and interred by their new self-sacrificing and determined masters. The regeneration of the fellaheen army dates from that epidemic.

When the Egyptian Army of the Delta was dispersed at Tel-el-Kebir, the Khedive had 40,000 troops in the Sudan, scattered from Massawa on the Red Sea to 1200 miles towards the west, and from Wadi Halfa, 1500 miles southward to Wadelai, near Albert Nyanza. These were composed of Turks, Albanians, Circassians, and some Sudanese. Ten thousand fellaheen, collected in March 1883, mainly from Arabi's former forces, set out from Duem, 100 miles south of Khartum, in September 1883, under Hicks Pasha, a dauntless retired Indian Army officer, to vanquish the Mahdi. They disappeared in the deserts

of Kordofan, where they were destroyed by the Mahdists about 50 miles south of El Obeid. In the wave of successful rebellion, except at Khartum, few of the Egyptian garrisons were killed when the posts fell, long residence and local family ties rendering easy their assimilation in the ranks of the Mahdists.

Baker Pasha, with about 4000 constabulary, who were old soldiers, attempted to relieve Tokar in February 1884. He was attacked by 1200 tribesmen and utterly routed, losing 4 Krupp guns, 2 machine guns, and 3000 rifles. Only 1400 Egyptians escaped the slaughter.

The Sirdar made an attempt to raise a battalion of Albanians, but the few men obtained mutinied when ordered to proceed to the Sudan, and it was deemed advisable, after the ringleaders had been executed, to abandon the idea, and rely on blacks to stiffen the fellaheen. Then the 9th (Sudanese) Battalion was created for service at Suakin, and four others having been successively added, these (with one exception—at Gedaref) have since borne the brunt of all the fighting which has been done by the Khedivial troops. The Egyptian troops in the operations near Suakin behaved well, however; and there were many instances of personal gallantry by individual soldiers. In the autumn of 1884, when a British expedition went up the Nile to endeavour to relieve the heroic Gordon, besieged in Khartum, the Egyptians did remarkably good work on the line of communication from Assiut to Korti, a distance of 800 miles, and the training and experience thus gained were of great value in all subsequent operations. The honesty and discipline of the fellah were undoubtedly of a high order. When the crews of the whale-boats were conveying stores, the forwarding officers tried to keep brandy and such like medical comforts from the European crews, coffee and tea from Canadian voyageurs, and sugar from Kroo boys. The only immaculate carrier was the Egyptian. A large sum of specie having failed under British escort to reach Dongola, an equivalent sum was handed to an Egyptian lieutenant of six months' service, with 10 men, and duly reached its destination.

Twelve years later the standard of honesty was unimpaired, and the British officers had imparted energy and activity into Egyptians of all ranks. The intelligent professional knowledge of the native officers, taught under British gentlemen, and the constant hard work cheerfully rendered by the fellah soldiers, were the main factors of the success achieved at Omdurman on the 2nd September 1898. The large depôts of stores at Assuan, Halfa, and Dongola could only be cursorily supervised by British officers, and yet when the stores were received at the advance depôt the losses were infinitesimal.

***Character of Egyptian soldier.***

By nature the fellah is unwarlike. Born in the valley of a great river, he resembles in many respects the Bengali, who exists under similar conditions; but the Egyptian has proved capable of greater improvement. He is stronger in frame, and can undergo greater exertion. Singularly unemotional, he stood up at Tel-el-Kebir after Arabi Pasha and all his officers, from general to subaltern, had fled, until he was mown down by case-shot poured in at close ranges. Near Trinkitat in 1883 he allowed himself to be slaughtered by tribesmen formerly despised, and about one-fourth of his comrades escaped. Baker Pasha's force was termed constabulary, yet his men were all old soldiers, though new to their gallant leader and to the small band of their brave but strange British officers. Since that fatal day, however, many of the fellaheen have shown they are capable of devoted conduct, and much has been done to raise in the soldiers a sense of self-respect, and, in spite of centuries of oppression, of veracity. The barrack square drill was smart under the old system, but there was no fire discipline, and all individuality was crushed. Now both are encouraged, and the men, receiving their full rations, are unsurpassable in endurance at work and in marching. All the troops present in the surprise fight at Firket in June 1896 had covered long distances, and one battalion (the 10th Sudanese) accomplished 90 miles within 72 hours, including the march back to railhead immediately after the action. The troops under Colonel Parsons, Royal Artillery, who beat the Dervishes at Gedaref, were so short of British officers that all orders were necessarily given in Arabic and carried to commanders of units by Arabs. While an Egyptian battalion was attacking in line, it was halted to repel a rush from the rear, and front and rear ranks were simultaneously engaged, firing in opposite directions—yet the fellaheen were absolutely steady; they shot well and showed no signs of trepidation. On the other hand, neither was there any exultation after their victory. It has been said by one who has perhaps more knowledge of them than any other commander, that "the fellah would make an admirable soldier if he only wished to kill some one!"

The well-educated Egyptian officer, with his natural aptitude for figures, does subordinate regimental routine carefully, and works well when supervised by men of stronger character. The ordinary Egyptian is not self-reliant or energetic by nature, and, like most Eastern people, finds it difficult to be impartial where duty and family or other personal relations are in the balance. The black soldier has, on the other hand, many of the finest fighting qualities. This was observed by British officers, from the time of the preliminary operations about Kosheh, and at the action near Ginniss in December 1885, down to the brilliant operations in the pursuit of the Mahdists on the Blue Nile after the action of Gedaref (subsequent to the battle of Omdurman), and the fighting in Kordofan in 1899, which resulted in the death of the Khalifa and his Emirs.

Black soldiers served in Mehemet Ali's army, but their value was not then duly appreciated. At the present day (1902) they are nearly all deserters from the Mahdist forces, or prisoners who have been captured in action. The greater number are Shilluks and Dinkas, coming from the country between Fashoda and the Equatorial Provinces, but a proportion come from the far west of Kordofan, some even from Bornu and Wadai. Many are absolute savages, difficult to control, wayward, and thoughtless like children. They are very excitable and apt to get out of hand; unlike the fellahs, they are not fond of drill, and are slow to acquire it, but their dash, their pugnacious instinct, and their desire to close with an enemy are of immense value. The Sudani, moreover, shoots better than the fellah, whose eyesight is often defective. The Sudanese captain can seldom read or write, and is therefore in the hands of the Egyptian-born company quartermaster-sergeant as regards pay and clothing accounts. He is slow, and as a rule has little knowledge of drill. Nevertheless he is self-reliant, much respected by his men, and can be trusted in the field to carry out any orders received from his British officer. The younger Sudanese officers who have been through the Military School are well instructed, but it is said that the Sudanese brought up in Cairo have lost, in some respects, the robust martial qualities inherent in the Sudan people. The most efficient companies in the Sudanese battalions are apparently those in which the captain is a black and the lieutenants are Egyptians.

The army raised by the first Sirdar in January 1883 was highly commended for its work on the line of communication in 1884–85, and its artillery and camelry distinguished themselves in the action at Kirbekan in

February 1885. Colonel Sir Francis Grenfell succeeded General Sir Evelyn Wood in March 1885, and while under his command the army continued to improve, and fought successful actions at Gemazah, Arguin, Toski, and Tokar. At Toski the Dervish force was nearly annihilated. In March 1892 Colonel Kitchener succeeded General Sir Francis Grenfell, and four years later began his successful reconquest of the Sudan. In June 1896, owing to the indefatigable exertions of Major Wingate, a perfected system of secret intelligence enabled the Sirdar to bring an overwhelming force of 6 to 1 against the Dervish outpost at Firket and destroy it. In September 1896 a skirmish at Hafir, with similarly successful tactics, gave the British commander the possession of Dongola. On the 7th August 1897 Colonel Hunter surprised and annihilated a weak Dervish garrison at Abu Hamed, to which place, by the 31st October 1897, a railway had been laid across the Nubian desert from Wadi Halfa, a distance of 230 miles, the "record" construction of 5300 yards surveyed, embanked, and laid in one day having been attained. On the 26th December 1897 the Italian troops handed over Kassala to Colonel Parsons, R.A. On the 8th April 1898 a British division, with the Egyptian army, destroyed the Dervish force under the Emir Mahmud Ahmed, on the Atbara river. On the 2nd September the Khalifa attacked the British-Egyptian troops at Kerreri, and being routed, his men dispersed; Omdurman was occupied, and on the 19th September the Egyptian flag was rehoisted at Fashoda. On the 22nd September 1898 Gedaref was taken from the Emir Ahmed Fedil by Colonel Parsons, and on the 26th December the army of Ahmed Fedil was finally defeated and dispersed near Roseires. The Khalifa's army, reduced to an insignificant number, after several unsuccessful engagements withdrew to the west of the Nile, where it was attacked, on the 24th November 1899, after a forced march by Colonel Wingate, and annihilated. The Khalifa himself was killed; while the victor, who had joined the Egyptian army in 1883 as aide-de-camp to the first Sirdar, in December 1899 became the fourth Sirdar, as Major-General Sir F. R. Wingate, K.C.B., K.C.M.G., &c.

The single Camel Company of 1883 grew by 1901 into six companies. A raid from Dongola into the Oasis of Beris caused the Sirdar to raise three companies of Sudanese drafted from the battalions, to which two more companies were added in 1896, one of fellaheen and one composed of Dervishes taken at Dongola. Six days' food for men and camels, 300 rounds for each rifle, and three days' water for men are carried in marching order.

In 1899 the infantry of the Egyptian army consisted of 20,000 men, of whom 12,000 were fellaheen and 8000 blacks, divided into battalions of 1000 and 800 men respectively. They are armed with Martini-Henry rifles, and carry into action 130 rounds per man, 80 being in the pouches and 50 in the bandoliers. In 1901 the infantry, reduced by 2 battalions since the war, numbered 9 Egyptian and 7 Sudanese battalions.

The artillery consists of 4 field batteries and 1 Maxim battery, each battery having one British officer and 5 Egyptian, the total comprising 34 officers and 900 men. There is a battalion of 3 companies of garrison artillery, consisting of 12 officers and 370 men.

There are 10 gunboats on the Nile, and a number of unarmed vessels.

The cavalry are mounted on hardy Syrian horses; there are 5 squadrons, one being composed of Sudanese raised after the battle of Omdurman, and the remainder of Egyptians. Three squadrons are commanded by British officers, and two by native officers, each squadron having an average strength of 150. The front ranks carry lance and carbine, and the rear ranks carbine and sword.

The Egyptian soldier, when unfit for duty, had, under the pre-British command, been treated in civil hospitals, but there was a civilian doctor paid on Army Estimates, who was supposed to supervise the conscription, to avoid which large sums were given as bribes. An outbreak of cholera in the summer of 1883 emphasized the necessity of British doctors, and Surgeon-Major Rogers organized a singularly efficient department, which now consists of 14 British officers, 39 Egyptian officers, and 284 non-commissioned officers and men.

The Veterinary Department, represented originally by a single British veterinary officer, who joined in 1883, now consists of two British officers and five Egyptian officers, with 30 non-commissioned officers and men, who are selected for intelligence and education after one year's service in the ranks.

The ambitious Military School system of the Khedive Ismail Pasha was replaced, in consequence of financial pressure, by a smaller establishment in 1879, but, partly out of consideration for the capable French officer then at its head, no drastic changes were enforced in 1883, nor until 1887, when the notoriously bad state of the school necessitated its reorganization, which was effected by a British officer. A simpler programme was adopted: elementary subjects were more thoroughly taught, and a knowledge of arithmetic, geometry, algebra, fortification, military history, topography, drawing, geography, English, French, and Arabic was imparted. The 200 students remain for two years; the course is calculated to last for three years, but at present the demand for officers exceeds the output.

The Supply Department is supervised by a British officer as director, who has under him the Tura Mills, where biscuits and soap are produced much more cheaply than was possible under the contract system. A British officer supervises the stores, clothing, and equipment for both man and horse. The clothing for all arms of the service costs between £3 and £4 per head, and the rations from 4d. to 5d. daily for each soldier. Guns and equipment of all kinds are, as a rule, purchased in the United Kingdom. The total annual expenditure is £500,000.

On the assumption of command by the third Sirdar, then Colonel Kitchener, the Surveyor-General's Department was abolished; the Engineer, Ordnance, and Supply services were administered as separate branches, while to a Financial Secretary was given the duty of preparing the Budget and making contracts, issuing pay, and carrying out a financial audit.

The army has been gradually reduced since the Dervish wars, and large numbers of officers and men are now employed in the civil administration of the Sudan. (E. WO.)

## Political History.

In the ninth edition of this Encyclopædia (vol. v. p. 767) an account is given of the reforms instituted during the Khediviate of Ismail Pasha, but it is justly pointed out that "the funds required for these public works, as well as the actual labour, have been remorselessly extorted from a poverty-stricken population, and there is probably no peasant now existing whose condition is worse than that of the long-suffering Egyptian fellah." The writer ventured however, to predict that "future generations will gain at the fearful expense of the present," and that "a better time is beginning for Egypt." This prediction, made in 1877, has since been fulfilled; but the better time has come in a way and to an extent which no one could have then foreseen.

***Steps leading to the deposition of Ismail.***

The impoverishment of the fellah had reached in 1875 such a point that the ordinary resources of the country no longer sufficed for the most urgent necessities of administration; and the Khedive Ismail, having repeatedly broken faith with his creditors, could not raise any more loans on the European market. The taxes were habitually collected many months in advance, and the colossal floating debt was increasing rapidly. In these circumstances Ismail had to realize his remaining assets, and among them sold 176,602 Suez Canal shares to the British Government for £3,976,582 (see BEACONSFIELD). This comparatively small financial operation brought about the long-delayed crisis and paved the way for the future prosperity of Egypt, for it induced the British Government to inquire more carefully into the financial condition of the country. What is known as the Cave Mission was sent out to Cairo in 1875, and its report showed that under the existing administration national bankruptcy was inevitable. Other commissions of inquiry followed, and each one brought Ismail more under European control. The establishment of the Mixed Tribunals (*Ency. Brit.* vol. v. p. 767) had already made

some of the Courts of Justice international. The Caisse de la Dette, the result of the Cave Mission, established international control over a large portion of the revenue. By the Goschen Mission, the next in order of time, the State railways were internationalized. Then came the Rivers Wilson Mission, in consequence of which the control was extended to the enormous landed property of the Khedive. Driven to desperation, Ismail made a virtue of necessity and accepted, in September 1878, a Constitutional Ministry, under the presidency of Nubar Pasha, with Rivers Wilson as Minister of Finance and De Blignières as Minister of Public Works. Professing to be quite satisfied with this arrangement, he pompously announced that Egypt was no longer in Africa, but a part of Europe; but before seven months had passed he found his Constitutional position intolerable, got rid of his irksome Cabinet by means of a secretly-organized military riot in Cairo, and reverted to his old autocratic methods of government. England and France could hardly sit still under this affront, and decided to administer chastisement by the hand of the Suzerain Power, which was delighted to have an opportunity of asserting its authority. On 26th June 1879 Ismail suddenly received from the Sultan a curt telegram, addressed to him as ex-Khedive of Egypt, informing him that his son Tewfik was appointed his successor. Taken unawares, he made no attempt at resistance, and Tewfik was at once proclaimed Khedive.

*Re-establishment of Dual Control.*

After a short period of inaction, when it seemed as if the change were for the worse, England and France summoned up courage to look the situation boldly in the face, and re-established the Dual Control in the persons of Major Baring and M. de Blignières. For two years the Dual Control governed Egypt, and initiated the work of progress that England was to continue alone. Its essential defect was what might be called insecurity of tenure. Without any efficient means of self-protection and coercion at its disposal, it had to interfere with the power, privileges, and perquisites of a class which had long misgoverned the country. This class, so far as its civilian members were concerned, was not very formidable, because these were not likely to go beyond the bounds of intrigue and passive resistance; but it contained a military element who had more courage, and who had learned their power when Ismail employed them for overturning his Constitutional Ministry. Among the mutinous soldiers on that occasion was a fellah officer calling himself Ahmed Arabi the Egyptian. He was not a man of exceptional intelligence or remarkable powers of organization, but he was a fluent speaker, and could exercise some influence over the masses by a rude kind of native eloquence. Behind him were a group of men, much abler than himself, who put him forward as the figurehead of a party professing to aim at protecting the Egyptians from the grasping tyranny of their Turkish and European oppressors. The movement began among the Arab officers, who complained of the preference shown to the officers of Turkish origin; it then expanded into an attack on the privileged position and predominant influence of foreigners, many of whom, it must be confessed, were of a by no means respectable type; finally it was directed against all Christians, foreign and native. The Government, being too weak to suppress the agitation and disorder, had to make concessions, and each concession produced fresh demands. Arabi was first promoted, then made Under-Secretary for War, and ultimately a member of the Cabinet. The danger of a serious rising brought the British and French fleets in May 1882 to Alexandria, and after a massacre (11th June) had been perpetrated by the Arab mob in that city, the British Admiral bombarded the forts (11th July 1882). The leaders of the National Movement prepared to resist further aggression by force. A conference of Ambassadors was held in Constantinople, and the Sultan was invited to quell the revolt; but he hesitated to employ his troops against Mussulmans who were professing merely to oppose Christian aggression. At last the British Government determined to employ armed force, and invited France to co-operate. The French Government declined, and a similar invitation to Italy met with a similar refusal. England therefore, having to act alone, landed troops at Ismailia under Sir Garnet Wolseley, and suppressed the revolt by the battle of Tel-el-Kebir on 13th September 1882. The Khedive, who had taken refuge in Alexandria, returned to Cairo, and a Ministry was formed under Sherif Pasha, with Riaz Pasha as one of its leading members. On assuming office, the first thing it had to do was to bring to trial the chiefs of the rebellion. Had the Khedive and Riaz been allowed a free hand, Arabi and his colleagues would have found little mercy. Thanks to the intervention of the British Government, their lives were spared. Arabi pleaded guilty, was sentenced to death, the sentence being commuted by the Khedive to banishment; and Riaz resigned in disgust. This solution of the difficulty was brought about by Lord Dufferin, then British Ambassador at Constantinople, who had been sent to Egypt as High Commissioner to adjust affairs and report on the situation. One of his first acts, after preventing the application of capital punishment to the ringleaders of the revolt, was to veto the project of protecting the Khedive and his Government by means of a Prætorian guard recruited from Asia Minor, Epirus, Austria, and Switzerland, and to insist on the principle that Egypt must be governed in a truly liberal spirit. Passing in review all the departments of the administration, he laid down the general lines on which the country was to be restored to order and prosperity, and endowed, if possible, with the elements of self-government for future use.

*Arabi and the revolt of 1882.*

*Single-handed British intervention.*

*Sir Evelyn Baring appointed Consul-General, 1884.*

The laborious task of putting these general indications into a practical shape fell to Sir Evelyn Baring, who arrived as Consul-General and Diplomatic Agent, in succession to Sir Edward Malet, in January 1884. At that moment the situation was singularly like that which had existed on two previous occasions: firstly, when Ismail was deposed, and secondly, when the Dual Control had undermined the existing authority without having any power to enforce its own. For the third time in little more than three years the existing authority had been destroyed and a new one had to be created. But there was one essential difference: the power that had now to reorganize the country possessed in the British army of occupation a support sufficient to command respect. Without that support Sir Evelyn Baring could have done little or nothing; with it he did perhaps more than any other single man could have done. His method may be illustrated by an old story long current in Cairo. Mohammed Ali was said to have appointed as Mudir or governor in a turbulent district a young and inexperienced Turk, who asked, "But how am I to govern these people?" "Listen," replied the Pasha; "buy the biggest and heaviest *kurbash* you can find; hang it up in the centre of the Mudirieh, well within your reach, and you will very seldom require to use it." The British army of occupation was Sir Evelyn's *kurbash;* it was well within his reach, as all the world knew, and its simple presence sufficed to prevent disorder and enforce obedience. He had one other advantage over previous English reformers in Egypt: his position towards France was more independent. The Dual Control had been abolished by a Khedivial decree of 18th January 1883,

and replaced by an English financial adviser. France naturally objected; but having refused to co-operate with England in suppressing the revolt, she could not reasonably complain that her offer of co-operation in the work of reorganization was declined.

*The policy of evacuation.*

At first the intention of the British Government was simply to restore the power of the Khedive, to keep His Highness for some time in the right path by friendly advice, and to withdraw the British troops as soon as possible. As Lord Granville explained in a Circular to the Powers, the position of England in Egypt imposed on her "the duty of giving advice with the object of securing that the order of things to be established shall be of a satisfactory character and possess the elements of stability and progress." But there was to be no embarking on a general scheme of reforms, which would increase unnecessarily the responsibilities of the protecting Power and necessitate the indefinite prolongation of the military occupation. So far, therefore, as the British Government had a definite policy in Egypt, it was a *politique de replâtrage.* Even this policy was not strictly adhered to. Mr Gladstone's Cabinet was as unstable as the public opinion it sought to conciliate. It had its hot fits and its cold fits, and it gave orders now to advance and now to retreat. In the long-run circumstances proved too strong for it, and it had to undertake a great deal more than it originally intended. Each little change in the administration engendered a multitude of others, so that the modest attempts at reform were found to be like the letting out of water. A tiny rill gradually became a boisterous stream, and the boisterous stream grew into a great river, which spread to all sections of the administration and ended by inundating the whole country.

*The Sudan question.*

Of the numerous questions awaiting solution, the first to claim immediate attention was that of the Sudan. The British Government had begun by excluding it from the problem, and by declaring that for events in these outlying territories it must not be held responsible. In that sphere of activity, therefore, the Egyptian Government might do as it thought fit. The principle of limited liability which this attitude assumed was soon found to be utterly untenable. The Sudan was an integral part of the Khedive's dominions and caused, even in ordinary times, a deficit of £200,000 to the Egyptian Treasury. At that moment it was in a state of open rebellion, stirred up by a religious fanatic who proclaimed himself a Mahdi or Messias of Islam. An army of 10,000 men under an English general, Hicks Pasha, had been sent to suppress the revolt, and had been annihilated in a great battle fought on 5th November 1883, near Obeid. The Egyptian Government wished to make a new attempt to recover the lost province, and the idea was certainly very popular among the governing class, but Sir Evelyn Baring vetoed the project on the ground that Egypt had neither soldiers nor money to carry it out. In vain the Khedive and his Prime Minister, Sherif Pasha, threatened to resign, and the latter actually carried out his threat. The British representative remained firm, and it was decided that the Sudan should be, for the moment at least, abandoned to its fate. Nubar, though as strongly opposed to the abandonment policy as Sherif, consented to take his place and accepted somewhat reluctantly the new régime, which he defined as "the administration of Egypt under the government of Baring." By this time the Mahdi was master of the greater part of the Sudan, but Khartum and some other fortified points still held out. The efforts made to extricate the garrisons, including the mission of General Gordon, the fall of Khartum, and the Nile Expedition under Lord Wolseley are described below, in the account given of military operations. The practical result was that the Khedive's authority was limited to the Nile Valley north of Wadi Halfa.

*Internal reorganization.*

With the internal difficulties Sir Evelyn Baring had been struggling bravely ever since his appointment, trying to evolve out of the ever-changing policy and contradictory orders of the British Government some sort of coherent line of action, and to raise the administration to a higher standard. For two or three years it seemed doubtful whether he would succeed. All over Egypt there was a feeling of unrest, and the well-meant but not very successful efforts of the British to improve the state of things were making them very unpopular. The introduction of English officials and English influence into all the administrative departments was resented by the native officials, and the action of the irrigation officers in preventing the customary abuses of the distribution of water was resented by the great landowners, who had been, from time immemorial, in the habit of taking as much as they wanted, to the detriment of the fellaheen. Even these latter, who gained most by the reforms, considered that they had good reason to complain, for the defeat of Arabi and the re-establishment of order had enabled the Christian money-lenders to return and insist on the payment of claims, which were supposed to have been extinguished by the rebellion. Worst of all, the Government was drifting rapidly towards insolvency, being quite unable to fulfil its obligations to the bondholders and meet the expenses of administration. All departments were being starved, and even the salaries of poorly paid officials were in arrear. To free itself from its financial difficulties the Government adopted a heroic remedy which only created fresh troubles. On the advice of Lord Northbrook, who was sent out to Cairo in September 1884 to examine the financial situation, certain revenues which should have been paid into the Caisse for the benefit of the bondholders were paid into the Treasury for the ordinary needs of the administration. Immediately the Powers protested against this infraction of the law of liquidation, and the Caisse applied for a writ to the Mixed Tribunals. In this way the heroic remedy failed, and to the internal difficulties were added international complications.

Fortunately for Egypt, the British Government contrived to solve the international difficulty by timely concessions to the Powers, and succeeded in negotiating the London Convention of March 1885, by which the Egyptian Government was relieved from some of the most onerous stipulations of the Law of Liquidation, and was enabled to raise a loan of £9,000,000 for an annual payment of £135,000. After paying out of the capital the sums required for the indemnities due for the burning of Alexandria and the deficits of the years 1882 and 1883, it still had a million sterling, and boldly invested it in the improvement of irrigation. The investment proved most remunerative, and helped very materially to save the country from bankruptcy and internationalism. The danger of being again subjected to the evils of an international administration was very great, for the London Convention contained a stipulation to the effect that if Egypt could not pay her way at the end of two years, another International Commission would be appointed.

To obviate this catastrophe the British reformers set to work most energetically. Already something in the way of retrenchment and reform had been accomplished. The public accounts had been put in order, and the abuses in the collection of the land tax removed. The constant drain of money and men for the Sudan had been stopped. A beginning had been made for creating a new army to

replace the one that had been disbanded and to allow of a portion of the British garrison being withdrawn. In this work Sir Evelyn Wood had shown much sound judgment as well as great capacity for military organization, and had formed an efficient force out of very unpromising material (see above, under ARMY). His colleague in the Department of Public Works, Sir Colin Scott Moncrieff, had been not less active. By mitigating the hardships of the *corvée*, and improving the irrigation system, on which the prosperity of the country mainly depends, he had conferred enormous benefits on the fellaheen, and had laid the foundation of permanent budgetary equilibrium for the future. Not less active was Sir Edgar Vincent, the Financial Adviser, who kept a firm hold on the purse-strings and ruthlessly cut down expenditure in all departments except that of irrigation.

***Relations between British and native officials.***

The activity of the British officials naturally produced a certain amount of discontent and resistance on the part of their Egyptian colleagues, and Lord Granville was obliged to declare very plainly that such resistance could not be tolerated. Writing (January 1884) to Sir Evelyn Baring, he said: "It should be made clear to the Egyptian Ministers and Governors of Provinces that the responsibility which for the time rests on England obliges H.M. Government to insist on the adoption of the policy which they recommend; and that it will be necessary that those Ministers and Governors who do not follow this course should cease to hold their offices." Nubar Pasha, who continued to be Prime Minister, resisted occasionally. What he chiefly objected to was direct interference in the provincial administration and the native tribunals, and he succeeded for a time in preventing such interference. Sir Benson Maxwell and Mr Clifford Lloyd, who had been sent out to reform the Departments of Justice and the Interior, after coming into conflict with each other were both recalled, and the reforming activity was for a time restricted to the Departments of War, Public Works, and Finance. Gradually the tension between natives and foreigners relaxed, and mutual confidence was established. Experience had evolved the working principle which was officially formulated at a much later period: "Our task is not to rule the Egyptians, but as far as possible to teach the Egyptians to rule themselves. . . . European initiative suggests measures to be executed by Egyptian agency, while European supervision controls the manner in which they are executed." If that principle had been firmly laid down and clearly understood at the beginning, a good deal of needless friction would have been avoided.

***International problems.***

The international difficulty remained. The British position in Egypt was anomalous, and might easily give rise to international complications. The Sultan might well protest against the military occupation of a portion of his Empire by foreign troops. It was no secret that France was ready to give him diplomatic support, and other Powers might adopt a similar attitude. Besides this, the British Government was anxious to terminate the occupation as soon as possible. With a view to regularizing the situation and accelerating the evacuation, Sir Henry Drummond Wolff was sent to Constantinople in August 1885 on a special mission. On 24th October of that year he concluded a preliminary Convention by which an Ottoman and an English High Commissioner, acting in concert with the Khedive, should reorganize the Egyptian army, tranquillize the Sûdan by pacific means, and consider what changes might be necessary in the civil administration. When the two Commissioners were assured of the security of the frontier and the good working and stability of the Egyptian Government, they should present reports to their respective Governments, and these should consult as to the conclusion of a Convention regulating the withdrawal of the English troops. Mukhtar Pasha and Sir Henry Drummond Wolff were appointed Commissioners, and their joint inquiry lasted till the end of 1886, when the former presented his report and the latter went home to report orally. The remaining stipulations of the preliminary Convention were duly carried out. Sir Henry Drummond Wolff proceeded to Constantinople and signed on 22nd May 1887 the definitive Convention, according to which the occupation should come to an end in three years, but England should have a right to prolong or renew it in the event of internal peace or external security being seriously threatened. The Sultan authorized the signature of this Convention, but under pressure of France and Russia he refused to ratify it. Technically, therefore, the preliminary Convention still remains in force, and in reality the Ottoman Commissioner continues to reside in Cairo.

***Progress of reform.***

The steadily increasing prosperity of the country during the years 1886 and 1887 removed the danger of national bankruptcy and international interference, and induced Sir Evelyn Baring to widen the area of administrative reforms. In the provinces the local administration and the methods of dispensing justice were still scandalously unsatisfactory, and this was the field to which the British representative next directed his efforts. Here he met with unexpected opposition on the part of the Prime Minister, Nubar Pasha, and a conflict ensued which ended in Nubar's retirement in June 1888. Riaz Pasha took his place, and remained in office till May 1891. During these three years the work of reform and the prosperity of the country made great progress. The new Egyptian army was so far improved that it gained successes over the forces of the Mahdi; the burden of the national debt was lightened by a successful conversion; the *corvée* was abolished; the land tax was reduced 30 per cent. in the poorest provinces, and in spite of this and other measures for lightening the public burdens, the budgetary surplus constantly increased; the quasi-judicial Special Commissions for Brigandage, which were at once barbarous and inefficient, were abolished; the native tribunals were improved, and Mr (afterwards Sir John) Scott, an Indian judge of great experience and sound judgment, was appointed judicial adviser to the Khedive. This appointment was opposed by Riaz Pasha, and led to his resignation on the plea of ill-health. His successor, Mustafa Pasha Fehmi, continued the work and co-operated cordially with the English officials. The very necessary reform of the native tribunals was then taken seriously in hand. The existing procedure was simplified and accelerated; the working of the Courts was greatly improved by a carefully organized system of inspection and control; the incompetent judges were eliminated and replaced by men of better education and higher moral character; and for the future supply of well-qualified judges, barristers, and law officials, an excellent school of law was established. If the progress made in this direction is maintained, the Native Courts may some day, under proper European control, replace the anomalous Mixed Tribunals, and remove all necessity for the inconvenient consular jurisdictions, which are at present protected by the Capitulations. Meanwhile the reforming activity has been extended to Prisons, Public Health, and Education, and has attained very satisfactory results without ruffling the religious susceptibilities of the people.

Only once since the retirement of Riaz has the policy of teaching the Egyptians to rule themselves led to friction with the native authorities. In January 1892 the Khedive Tewfik, who had always maintained cordial relations with Sir Evelyn Baring, died suddenly, and was

succeeded by his son, Abbas Hilmi, a young man without political experience, who failed at first to understand the peculiar situation in which a Khedive ruling under British protection is necessarily placed. Aspiring to liberate himself at once from foreign control, he summarily dismissed Mustafa Pasha Fehmi, whom he considered too amenable to English influence, and appointed in his place Fakhri Pasha, who was not a *persona grata* at the British Agency. Such an incident, which might have constituted a precedent for more important acts of a similar kind, could hardly be overlooked by the British representative. He had always maintained that what Egypt most required, and would require for many years to come, was an order of things which would render practically impossible any return to that personal system of government which had well-nigh ruined the country. The young Khedive was made, therefore, to understand that he must not make such changes in the administration without a previous agreement with the representative of the protecting Power; and a compromise was effected by which Fakhri Pasha retired, and the post of Premier was confided once more to Riaz. With this compromise the friction between the Khedive and Sir Evelyn Baring, who had now become Lord Cromer, did not end. For some time Abbas Hilmi clung to his idea of liberating himself from all control, and secretly encouraged a nationalist and anti-British agitation in the native press; but he gradually came to perceive the folly, as well as the danger to himself, of such a course, and accordingly refrained from giving any occasion for complaint or protest. In like manner the relations between the British officials and their Egyptian colleagues gradually became more cordial, so that it was found possible at last to reform the local administration in the provinces according to the recommendations of Mr J. L. Gorst, who had been appointed adviser to the Ministry of the Interior. Nubar Pasha, it is true, who succeeded Riaz as Prime Minister in April 1894, objected to some of Mr Gorst's recommendations, and in November 1895 resigned. He was succeeded by Mustafa Fehmi, who had always shown a conciliatory spirit, and who had been on that account, as above stated, summarily dismissed by the Khedive in January 1893. After his reinstatement the Anglo-Egyptian condominium worked without serious friction, and there is reason to believe that it will continue so to work in the future as long as England remains true to her mission and shows no signs of hesitation in carrying it out. In the Report by His Majesty's Agent and Consul-General on the finances, administration, and condition of Egypt presented to Parliament in 1901, Lord Cromer concluded by expressing his belief "that His Highness the Khedive's recent visit to England (in 1900), coupled with the very remarkable and touching sympathy displayed by every class of society in this country (Egypt) on the occasion of the death of Queen Victoria, will serve to cement more closely the bonds of friendship and goodwill which, now perhaps more than at any previous period, unite my own countrymen and the Egyptians."

***Accession of Abbas.***

The success of the Anglo-Egyptian condominium, and the consequent economic and financial prosperity of Egypt Proper, rendered it possible to recover from the Mahdists the Sudanese provinces (see below, *Military Operations in the Sudan*), and to delimit in that part of Africa, in accordance with Anglo-Egyptian interests, the respective spheres of influence of Great Britain and France. The arrangement was not effected without serious danger of a European conflict. Taking advantage of the temporary weakness of Egypt, the French Government formed the project of seizing the Upper Nile Valley and uniting her possessions in West Africa with those at the entrance to the Red Sea. With this object a small force under Major Marchand was sent from the French Congo into the Bahr-el-Ghazal, with orders to occupy Fashoda on the Nile; whilst a Franco-Abyssinian Expedition was despatched from the eastward, to join hands with Major Marchand. The small force from the French Congo reached its destination, and a body of Abyssinian troops, accompanied by French officers, appeared for a short time a little higher up the river; but the grand political scheme was frustrated by the victorious advance of an Anglo-Egyptian force under General Kitchener and the resolute attitude of the British Government. Major Marchand had to retire from Fashoda, and as a concession to French susceptibilities he was allowed to retreat by the Abyssinian route. By an agreement signed by Lord Salisbury and the French Ambassador on 21st March 1899, and appended as Art. IV. to the Anglo-French Convention of 14th June 1898, which dealt with the British and French spheres of influence in the region of the Niger, France was excluded from the basin of the Nile, and a line marking the respective spheres of influence of the two countries was drawn on the map from the northern frontier of the Congo Free State to the southern frontier of the Turkish province of Tripoli (see Africa: *History*).

***Fashoda.***

The administration of the Sudan was organized on the basis of an agreement between the British and Egyptian Governments signed on 19th January 1899. According to that agreement the British and Egyptian flags are used together, and the supreme military and civil command is vested in a Governor-General, who is appointed by the Khedive on the recommendation of the British Government, and who cannot be removed without the British Government's consent. So far the arrangement has worked well. The Governor-General, Sir Reginald Wingate, in his report dated Khartum, 30th January 1901, after giving an account of the progress made, says: "I cannot close this report without recording my appreciation of the manner in which officers, non-commissioned officers, soldiers, and officials—British, Egyptian, and Sudanese, without distinction—have laboured during the past year to push on the work of regenerating the country. Nor can I pass over without mention the loyal and valuable assistance I have received from many of the local Ulemas, Sheikhs, and Notables, who have displayed a most genuine desire to see their country once more advancing in the paths of progress and material and moral improvement." (D. M. W.)

***The Anglo-Egyptian Sudan.***

## British Military Operations of 1882–1885.

In February 1879 a slight outbreak of discharged officers and soldiers occurred at Cairo, which led to the despatch of British and French ships to Alexandria. On 26th June of that year Ismail Pasha was removed from Egypt, and Tewfik assumed the Khediviate, becoming practically the *protégé* of the two Western Powers. On 1st February 1881 a more serious disturbance arose at Cairo from the attempt to try three colonels, Ahmed Arabi, Ali Fehmy, and Abd-el-Al, who had been arrested as the ringleaders of the military party. The prisoners were released by force, and proceeded to dictate terms to the Khedive. Again British and French warships were despatched to Alexandria, and were quickly withdrawn, their presence having produced no apparent impression. It soon became clear that the Khedive was powerless, and that the military party, headed by Arabi, threatened to dominate the country. The "dual note," communicated to the Khedive on 6th January 1881, contained an intimation that Great Britain and France were prepared to afford material support if necessary; but the fall of Gambetta's Ministry produced a reaction, and both Governments

proceeded to minimize the meaning of their language. The Khedive was practically compelled to form a government in which Arabi was Minister of War and Mahmoud Sami Premier, and Arabi took steps to extend his influence throughout his army. The situation now became critically serious: for the third time ships were sent to Alexandria, and on 25th May 1882 the Consuls-General of the two Powers made a strong representation to Mahmoud Sami which produced the resignation of the Egyptian Ministry, and a demand, to which the Khedive yielded, by the military party for the reinstatement of Arabi. The attitude of the troops in Alexandria now became threatening; and on the 29th the British residents pointed out that they were "absolutely defenceless." This warning was amply justified by the massacres of 11th June, during which more than one hundred persons, including an officer and two seamen, were killed in the streets of Alexandria, almost under the guns of the ships in harbour. It was becoming clear that definite action would have to be taken, and on the 15th the Channel Squadron was ordered to Malta. By the end of June twenty-six warships, representing the navies of Great Britain, France, Germany, Italy, Austria, Russia, the United States, Spain, Greece, and Turkey, lay off the port of Alexandria, and large numbers of refugees were embarked. The order received by Admiral Sir Beauchamp Seymour on 3rd July was as follows:—

***Bombardment of Alexandria.***

Prevent any attempt to bar channel into port. If work is resumed on earthworks, or fresh guns mounted, inform Military Commander that you have orders to prevent it; and if not immediately discontinued, destroy earthworks and silence batteries if they open fire, having given sufficient notice to population, shipping, and foreign men-of-war.

On the 9th the Admiral received a report that working parties had been seen in Fort Silsileh "parbuckling two smooth-bore guns—apparently 32-pounders—towards their respective carriages and slides, which were facing in the direction of the harbour." Fort Silsileh was an old work at the extreme east of the defences of Alexandria, and its guns do not bear on the harbour. On the 10th an ultimatum was sent to Toulba Pasha, the Military Commandant, intimating that the bombardment would commence at sunrise on the following morning unless "the batteries on the isthmus of Ras-el-Tin and the southern shore of the harbour of Alexandria" were previously surrendered "for the purpose of disarming." The fleet prepared for action, and the bearer of the reply, signed by the President of the Council, and offering to dismount three guns in the batteries named, only succeeded in finding the flagship late at night. This proposal was rejected, and at 7 a.m. on 11th July the *Alexandra* opened fire and the action became general. The attacking force was disposed in three groups: (1) the *Alexandra*, *Sultan*, and *Superb*, outside the reef, to engage the Ras-el-Tin and the earth works under weigh; (2) the *Monarch*, *Invincible*, and *Penelope*, inside the harbour, to engage the Meks batteries; and (3) the *Inflexible* and *Temeraire*, to take up assigned stations outside the reef and to co-operate with the inshore squadron. The gunboats *Beacon*, *Bittern*, *Condor*, *Cygnet*, and *Decoy* were to keep out of fire at first and seek opportunities of engaging the Meks batteries. Meks fort was silenced by about 12.45 p.m., and a party from the *Invincible* landed and disabled the guns. As the fire delivered under way was not effective, the offshore squadron anchored at about 10.30 a.m., and succeeded in silencing Fort Ras-el-Tin at about 12.30 p.m., and Fort Adda, by the explosion of the main magazine, at 1.35 p.m. The *Inflexible* weighed soon after 8 a.m. and engaged Ras-el-Tin, afterwards attacking Forts Pharos and Adda. The *Condor*, followed by the *Beacon*, *Bittern*, and *Decoy*, engaged Fort Marabout soon after 8 a.m. till 11 a.m., when the gunboats were recalled. After the works were silenced, the ships moved in closer, with a view to dismount the Egyptian guns. The bombardment ceased at 5 p.m.; but a few rounds were fired by the *Inflexible* and *Temeraire* on the morning of the 12th at the right battery in Ras-el-Tin lines.

The bombardment of the forts of Alexandria is interesting as a gauge of the effect to be expected from the fire of ships under specially favourable conditions. The Egyptians at different times during the day brought into action about 33 R.M.L. guns (7-inch to 10-inch), 3 R.B.L. guns (40 prs.), and 120 S.B. guns (6·5-inch and 10-inch), with a few mortars. These guns were disposed over a coast-line of about 10 sea miles, and were in many cases indifferently mounted. The Egyptian gunners had been little trained, and many of them had never once practised with rifled ordnance. Of seventy-five hits on the hulls of the ships only five can with certainty be ascribed to projectiles from rifled guns, and thirty were unquestionably due to the old smoothbores, which were not provided with sights. The total loss inflicted was 6 killed and 27 wounded. The British ships engaged fired 1741 heavy projectiles (7-inch to 16-inch) and 1457 light (7-prs. to 64-prs.), together with 33,493 machine-gun and rifle bullets. The result was comparatively small. About 8 rifled guns and 19 smoothbores were dismounted or disabled and 4 and 1 temporarily put out of action respectively. A considerable portion of this injury was inflicted, after the works had been silenced, by the deliberate fire of the ships. As many as twenty-eight rifled guns and 140 smoothbores would have opened fire on the following day. The Egyptians made quite as good a stand as could be expected, but were driven from their guns, which they were unable to use with adequate effect; and the bombardment of Alexandria confirms previous experience, that the fire of ships cannot really compete with that of well-mounted and well-handled guns on shore.

In the afternoon of the 12th, fires, which were the work of incendiaries, began to break out in the best quarters of Alexandria; and the town was left to murder and pillage till the following day, when a party of bluejackets and marines was landed at about 3 p.m.

Military intervention being now imperatively demanded, a vote of credit for £2,300,000 was passed in the British House of Commons on 27th July. Five days later the French Government failed to secure a similar vote, and Great Britain was left to deal with the Egyptian question alone. An expeditionary force detailed from home stations and from Malta was organized in two divisions, with a cavalry division, corps troops, and a siege train, numbering in all about 25,000 men. An Indian contingent numbering about 7000 combatants, complete in all arms and with its own transport, was prepared for despatch to Suez. General Sir Garnet Wolseley was appointed Commander-in-Chief, with Lieut.-General Sir J. Adye as Chief of the Staff. The plan of operations contemplated the seizure of Ismailia as the base for an advance on Cairo, Alexandria and its suburbs to be held defensively, and the Egyptian forces in the neighbourhood to be occupied by demonstrations. The expeditionary force having rendezvoused at Alexandria, means were taken by Rear-Admiral Hoskins and Sir W. Hewett for the seizure of the Suez Canal. Under orders from the former, Captain Fairfax, R.N., occupied Port Said on the night of 19th August, and Commander Edwards, R.N., proceeded down the Canal, taking possession of the *gares* and dredgers, while Captain Fitzroy, R.N., occupied Ismailia after slight opposition. Before nightfall on 20th August the Canal was wholly in British hands. Meanwhile, leaving Sir E. Hamley in command at Alexandria, Sir G. Wolseley with the bulk of the expeditionary force arrived at Port Said on 20th August, a naval demonstration having been made at Abukir with a view to deceive the enemy as to the object of the great movement in progress. The advance from Ismailia now began. On the 21st Major-General Graham moved from Ismailia with about 800 men and a small naval force, occupying Nefiche, the junction with the Suez line, at 1.30 a.m. without opposition. On the

***British expedition under Sir Garnet Wolseley.***

22nd he made a reconnaissance towards Suez, and on the 23rd another to El-Magfar, 4 miles from Nefiche. It now appeared that the enemy had dammed the sweet-water canal and blocked the railway at Tel-el-Mahuta, where entrenchments had been thrown up and resistance seemed to be contemplated. At 4 a.m. on the 24th Sir Garnet Wolseley advanced with 3 squadrons of cavalry, 2 guns, and about 1000 infantry, placed under the orders of Lieutenant-General Willis. The enemy showed in force, estimated at 7000 with 12 guns, and a somewhat desultory action ensued. Reinforcements from Ismailia were ordered up, and the British cavalry, operating on the right, helped to check the enemy's attack, which showed little vigour. At night the troops, now reinforced by the Guards Brigade, an infantry battalion, 2 cavalry regiments, and 10 guns, bivouacked on the ground. Early on the morning of the 25th the advance was continued to Tel-el-Mahuta, which the enemy evacuated, while the mounted troops and horse artillery pressed on to Mahsameh, capturing the Egyptian camp, with 7 guns and large quantities of ammunition and supplies. On the same evening Major-General Graham, with about 1200 marines (artillery and light infantry), reached Mahsameh, and on the following day he occupied Kassassin without opposition. The advance guard had now outrun its communications and was actually short of food, while a considerable force was distributed at intervals along the line Ismailia–Kassassin. The situation on the 27th tempted attack by an enterprising enemy, and Major-General Graham's force, consisting of a squadron of the 19th Hussars, the York and Lancaster Regiment, the Duke of Cornwall's Light Infantry, the Marine Artillery Battalion and two R.H.A. guns, short of ammunition, was in danger of being overwhelmed by vastly superior numbers from Tel-el-Kebir. On the 28th Major-General Graham's troops were attacked, and after repulsing the enemy, made a general advance about 6.45 p.m. The cavalry, summoned by heliograph from Mahsameh, co-operated, and in a moonlight charge inflicted considerable loss. The British casualties amounted to 14 killed and 83 wounded. During the lull which followed the first action of Kassassin, strenuous efforts were made to bring up supplies and troops and to open up railway communication to the front. On 9th September the Egyptians again attacked Kassassin, but were completely repulsed by 9 a.m., with a loss of 4 guns, and were pursued to within extreme range of the guns of Tel-el-Kebir. The British casualties were 3 killed and 78 wounded. The three following days were occupied in concentrating troops at Kassassin for the attack on Tel-el-Kebir, held by about 38,000 men with 60 guns. The Egyptian defences consisted of a long line of trench ($2\frac{1}{2}$ miles) approximately at right angles to the railway and the sweet-water canal. At 11 p.m. on 12th September the advance of about 15,000 men commenced: the 1st Division, under Lieutenant-General Willis, was on the right, and the 2nd Division, under Lieutenant-General Hamley, was on the left. Seven batteries of artillery, under Brigadier-General Goodenough, were placed in the centre. The cavalry, under Major-General Drury Lowe, was on the right flank, and the Indian contingent, under Major-General Macpherson, starting one hour later, was ordered to move south of the sweet-water canal. The night was moonless, and the distance to be covered about $6\frac{1}{4}$ miles. The ground was perfectly open, slightly undulating, and generally firm gravel. The conditions for a night march were thus ideal; but during the movement the wings closed towards each other, causing great risk of an outbreak of firing. The line was, however, rectified, and after a halt the final advance began. By a fortunate accident the isolated outwork was just missed in the darkness by the left flank of the 2nd Division; otherwise a premature alarm would have been given, which must have changed all the conditions of the operation. At dawn the Highland Brigade of the 2nd Division struck the enemy's trenches, and carried them after a brief struggle. The 1st Division attacked a few minutes later, and the cavalry swept round the left of the line of entrenchments, cutting down any fugitives who attempted resistance and reaching the enemy's camp in rear. The Indian contingent, on the south of the canal, co-operated, intercepting the Egyptians at the canal bridge. The opposition encountered at some points was severe, but by 6 a.m. all resistance was at an end. The British loss amounted to 58 killed, 379 wounded, and 22 missing; nearly 2000 Egyptians were killed, and more than 500 wounded were treated in hospital. An immediate pursuit was ordered, and the Indian contingent, under Major-General Macpherson, reached Zagazig, while the cavalry, under Major-General Drury Lowe, occupied Belbeis and pushed on to Cairo, 65 miles from Tel-el-Kebir, next day. On the evening of the 14th the 10,000 troops occupying Abassiyeh Barracks, and 5000 in the Citadel of Cairo, surrendered. On the 15th General Sir Garnet Wolseley, with the Brigade of Guards under H.R.H. the Duke of Connaught, entered the city.

*Tel-el-Kebir.*

The prompt following up of the victory at Tel-el-Kebir saved Cairo from the fate of Alexandria and brought the rebellion to an end. The Egyptian troops at Kafr Dauar, Abukir, and Rosetta surrendered without opposition, and those at Damietta followed on 23rd September, after being threatened with attack. On the 25th the Khedive entered Cairo, where a review of the British troops was held on the 30th. The expeditionary force was now broken up, leaving about 10,000 men, under Major-General Sir A. Alison, to maintain the authority of the Khedive. In twenty-five days, from the landing at Ismailia to the occupation of Cairo, the rebellion was completely suppressed, and the operations were thus signally successful.

The authority of the Khedive and the maintenance of law and order now depended absolutely on the British forces left in occupation. Lord Dufferin, who had been sent to Cairo to draw up a project of constitutional reforms, advocated the re-establishment of a native army, not to exceed 5000 to 6000 men, with a proportion of British officers, for purely defence purposes within the Delta; and on 13th December 1882 Sir Evelyn Wood left England to undertake the organization of this force, with the title of Sirdar. Lord Dufferin further advised the formation of a gendarmerie, which "should be in a great measure a mounted force and empowered with a semi-military character" (despatch of 1st January 1883). The strength of this military police force was fixed at 4400 men with 2562 horses, and Baker Pasha was entrusted with its formation, with the title of Inspector-General. In a despatch of 6th February 1883 Lord Dufferin dealt with the Sudan, and stated that Egypt "could hardly be expected to acquiesce" in a policy of withdrawal from her Southern territories. At the same time he pointed out that,

*The Sudan question.*

Unhappily, Egyptian administration in the Sudan had been almost uniformly unfortunate. The success of the present Mahdi in raising the tribes and extending his influence over great tracts of country was a sufficient proof of the Government's inability either to reconcile the inhabitants to its rule or to maintain order. The consequences had been most disastrous. Within the last year and a half the Egyptians had lost something like 9000 men, while it was estimated that 40,000 of their opponents had perished.

Moreover, to restore tranquillity in the Sudan,

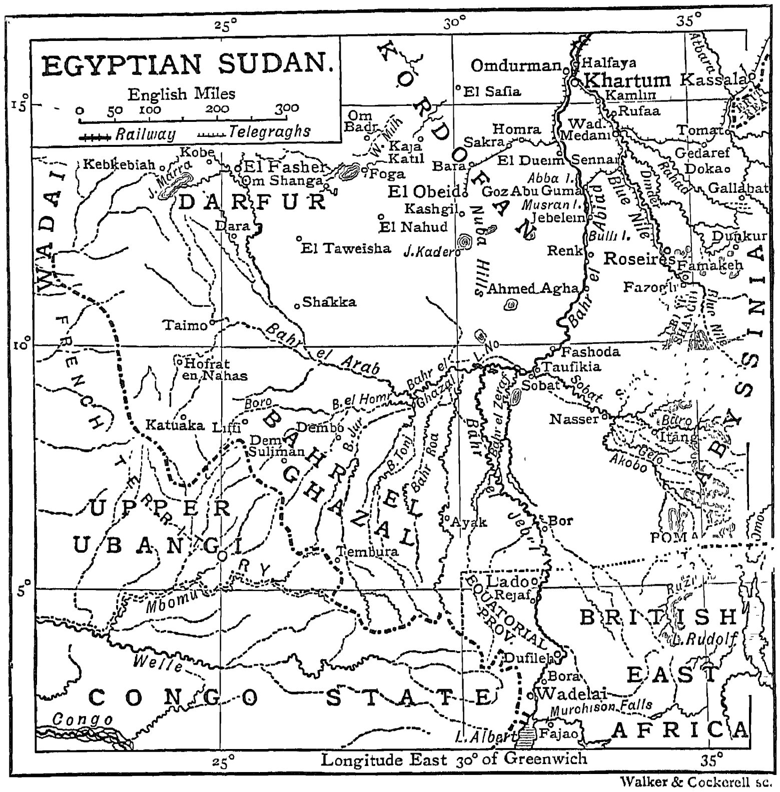
the first step necessary was the construction of a railway from Suakin to Berber, or, what, perhaps, would be more advisable, to

Shendi, on the Nile. The completion of this enterprise would at once change all the elements of the problem.

The immense responsibilities involved were most imperfectly understood by the British Government. Egyptian sovereignty in the Sudan dates from 1819, when Mehemet Ali sent a large force into the country, and ultimately established his authority over Sennar and Kordofan. In 1866 Suakin and Massawa were assigned to Egyptian rule by the Sultan, and in 1870 Sir Samuel Baker proceeded up the Nile to the conquest of the Equatorial Provinces, of which General Gordon was appointed Governor-General in 1874. In 1875 Darfur and Harrar were annexed, and in 1877 Gordon became Governor-General of the Sudan, where, with the valuable assistance of Jessi Pasha, he laboured to destroy the slave trade and to establish just government. In August 1879 he returned to Cairo, and was succeeded by Raouf Pasha. Misrule and oppression in every form now again prevailed throughout the Sudan, while the slave traders, exasperated by Gordon's stern measures, were ready to revolt. The authority of Egypt was represented by scattered garrisons of armed men, badly officered, undisciplined, and largely demoralized. In such conditions a leader only was required to ensure widespread and dangerous rebellion. A leader appeared in the person of Mahommed Ahmed, born in 1848, who had taken up his abode on Abba Island, and, acquiring great reputation for sanctity, had actively fomented insurrection. In August 1881 a small force sent by Raouf Pasha to arrest Mahommed Ahmed was destroyed, and the latter, proclaiming himself the *Mahdi*, stood forth as the champion of revolt. Thus at the time when the Egyptian army was broken up at Tel-el-Kebir, the Sudan was already in flames. On 7th June 1882, 6000 men under Yusef Pasha, advancing from Fashoda, were nearly annihilated by the Mahdists. Payara and Birket in Kordofan quickly fell, and a few days before the battle of Tel-el-Kebir was fought, the Mahdi, with a large force, was besieging El Obeid. By the close of the year almost the whole of the Sudan south of Khartum was in open rebellion, except the Bahr-el-Ghazal and the Equatorial Provinces, where for a time Lupton Bey and Emin Pasha were able to hold their own. Abd-el-Kader, who had succeeded Raouf, telegraphed to Cairo for 10,000 additional troops, and pointed out that if they were not sent at once four times this number would be required to re-establish the authority of the Government in the Sudan. After gaining some small successes, Abd-el-Kader was superseded by Suliman Niagi on 20th February 1883, and on 26th March Ala-ed-din Pasha was appointed Governor-General. Meanwhile 5000 men, who had served in the Egyptian army, were collected and forcibly despatched to Khartum *viâ* Suakin. In March 1883 Major-General Hicks, who in January had been appointed by the Khedive Chief of the Staff of the army of the Sudan, found himself at Khartum with nine European officers and about 10,000 troops of little military value. The reconquest of the Sudan having been determined upon, although Sir E. Malet reported that the Egyptian Government could not supply the necessary funds and that there was great risk of failure, General Hicks, who had resigned his post on 23rd July, and had been appointed Commander-in-Chief, started from Khartum on 9th September, with a total force of about 10,000 men, including non-combatants, for Kordofan. On 22nd May Sir E. Malet had informed Sherif Pasha that,

***Disaster to General Hicks.***

although General Hicks finds it convenient to communicate with Lord Dufferin or with me, it must not be supposed that we endorse in any way the contents of his telegrams. . . . Her Majesty's Government are in no way responsible for his operations in the Sudan, which have been undertaken under the authority of His Highness's Government.



Walker & Cockerell sc.

General Hicks was fully aware of the unfitness of his rabble forces for the contemplated task, and on 5th August he telegraphed: "I am convinced it would be best to keep the two rivers and province of Sennar, and wait for Kordofan to settle itself." Early in November the force from Khartum was caught by the Mahdists short of water at Kashgil, near El Obeid, and was almost totally destroyed, General Hicks, with all his European officers, perishing. Sinister rumours having reached Cairo, Sir E. Baring, who had succeeded Sir E. Malet, telegraphed that "if General Hicks's army is destroyed, the Egyptian Government will lose the whole of the Sudan, unless some assistance from the outside is given," and advised the withdrawal to some post on the Nile. On the following day Lord Granville replied: "We cannot lend English or Indian troops; if consulted, recommend abandonment of the Sudan within certain limits"; and on the 25th he added that "Her Majesty's Government can do nothing in the matter which would throw upon them the responsibilities for operations in the Sudan." In a despatch of 3rd December Sir E. Baring forcibly argued against British intervention in the affairs of the Sudan, and on 13th December Lord Granville telegraphed that "Her Majesty's Government recommend the Ministers of Khedive to come to an early decision to abandon all territory south of Assuan, or, at least, of Wadi Halfa." On 4th January 1884 Sir E. Baring was directed to insist upon the policy

of evacuation, and on the 18th General Gordon left London to assist in its execution.

The year 1883 brought a great accession of power to the Mahdi, who had captured about 20,000 rifles, 19 guns, and large stores of ammunition. On the Red Sea littoral Osman Digna, a slave dealer of Suakin, appointed Emir of the Eastern Sudan, raised the local tribes and invested Sinkat and Tokar. On 16th October and 4th November Egyptian reinforcements intended for the former place were destroyed, and on 2nd December a force of 700 men was annihilated near Tamanieb. On 23rd December General Baker, followed by about 2500 men, gendarmerie, blacks, Sudanese, and Turks, with 10 British officers, arrived at Suakin to prepare for the relief of Sinkat and Tokar. The Khedive appears to have been aware of the risks to be incurred, and in a private letter he informed the general that "I rely upon your prudence and ability not to engage the enemy except under the most favourable circumstances." The tragedy of Kashgil was repeated on 4th February 1884, when General Baker's heterogeneous force, on the march from Trinkitat to Tokar, was routed at El Teb by an inferior body of tribesmen. Of 3715 men, 2375, with 11 European officers, were killed. Suakin was now in danger, and on 6th February British bluejackets and marines were landed for the defence of the town.

***Defeat of General Baker.***

Two expeditions in the Sudan led by British officers having thus ended in disaster, and General Gordon with Lieutenant-Colonel Stewart having reached Khartum on 18th February, the policy of British non-intervention in regard to Sudan affairs could no longer be maintained. Public opinion in England was strongly impressed by the fact that the Egyptian garrisons of Tokar and Sinkat were perishing within striking distance of the Red Sea littoral. A British force about 4400 strong, with 22 guns, made up of troops from Egypt and from units detained on passage from India, was rapidly concentrated at Suakin and placed under the orders of Major-General Sir G. Graham, with Major-Generals Sir R. Buller and J. Davis as Brigadiers. News of the fall of Sinkat, where the starving garrison, under Tewfik Bey, made a gallant sortie and was cut to pieces, reached Suakin on 12th February. On the 24th General Graham's force disembarked at Trinkitat and received information of the surrender of Tokar. At 8 a.m. on the 29th the force advanced towards Tokar in square, and came under fire at 11.20 a.m. from the enemy entrenched at El Teb. The tribesmen made desperate efforts to rush the square, but were repulsed, and the position was taken by 2 p.m. The cavalry, 10th and 19th Hussars, under Brigadier-General H. Stewart, became involved in a charge against an unbroken enemy, and suffered somewhat severely. The total British loss was 34 killed and 155 wounded; that of the tribesmen was estimated at 1500 killed. On the following day Tokar was reached, and on 2nd March the force began its return to Suakin, bringing away about 700 people belonging to the late garrison and the civil population, and destroying 1250 rifles and a quantity of ammunition found in a neighbouring village. On 9th March the whole force was back at Suakin, and on the evening of the 11th an advance to Tamai began, and the force bivouacked and formed a zeriba in the evening. Information was brought by a native that the enemy had assembled in the Khor Ghob, a deep ravine not far from the zeriba. At about 8.30 a.m on the 13th the advance began in echelon of brigade squares from the left. The left and leading square (2nd Brigade) moved towards the Khor, approaching at a point where a little ravine joined it. The enemy showing in front, the leading face of the square was ordered to charge up to the edge of the Khor. This opened the square, and a mass of tribesmen rushed in from the small ravine. The brigade was forced back in disorder, and the naval guns, which had been left behind, were temporarily captured. After a severe hand-to-hand struggle, in which the troops behaved with great gallantry, order was restored and the enemy repulsed, with the aid of the fire from the 1st Brigade square and from dismounted cavalry. The 1st Brigade square, having a sufficient field of fire, easily repelled all attempts to attack, and advancing as soon as the situation had been restored, occupied the village of Tamai. The British loss was 109 killed and 104 wounded; of the enemy nearly 2000 were killed. On the following day the force returned to Suakin.

***British expedition under Sir G. Graham: battles of El Teb and Tamanieb.***

Two heavy blows had now been inflicted on the followers of Osman Digna, and the road to Berber could have been opened, as General Graham and Colonel H. Stewart suggested. General Gordon, questioned on the point, telegraphed from Khartum, on 7th March, that he might be cut off by a rising at Shendi, adding, "I think it, therefore, most important to follow up the success near Suakin by sending a small force to Berber." He had previously, on 29th February, urged that the Suakin–Berber road should be opened up by Indian troops. This, and General Gordon's proposal to send 200 British troops to Wadi Halfa, was opposed by Sir E. Baring, who, realizing soon afterwards the gravity of the situation, telegraphed on 16th March:—

It has now become of the utmost importance not only to open the road between Suakin and Berber, but to come to terms with the tribes between Berber and Khartum.

The Government refused to take this action, and Major-General Graham's force was employed in reconnaissances and small skirmishes, ending in the destruction of the villages in the Tamanieb Valley on 27th March. On the 28th the whole force was reassembled at Suakin, and was then broken up, leaving one battalion to garrison the town.

The abrupt disappearance of the British troops encouraged the tribesmen led by Osman Digna, and effectually prevented the formation of a native movement, which might have been of great value. The first attempt at intervention in the affairs of the Sudan was made too late to save Sinkat and Tokar. It resulted only in heavy slaughter of the tribesmen, which afforded no direct or indirect aid to General Gordon or to the policy of evacuation. The public announcement of the latter was a grave mistake, which increased General Gordon's difficulties, and the situation at Khartum grew steadily worse. On 24th March Sir E. Baring telegraphed:—

***Entanglement of General Gordon at Khartum.***

The question now is, how to get General Gordon and Colonel Stewart away from Khartum. . . . Under present circumstances, I think an effort should be made to help General Gordon from Suakin, if it is at all a possible military operation. . . . We all consider that, however difficult the operations from Suakin may be, they are more practicable than any operations from Korosko and along the Nile.

A telegram from General Gordon, received at Cairo on 19th April, stated that,

We have provisions for five months and are hemmed in. . . . Our position will be much strengthened when the Nile rises. . . . Sennar, Kassala, and Dongola are quite safe for the present.

At the same time he suggested "an appeal to the millionaires of America and England" to subscribe money for the cost of "2000 or 3000 Nizams" (Turkish regulars) to be sent to Berber. A cloud now settled down upon Khartum, and subsequent communications were few and irregular. The Foreign Office and General Gordon appeared to be somewhat at cross purposes. The former

hoped that the garrisons of the Sudan could be extricated without fighting. The latter, judging from the tenor of some of his telegrams, believed that to accomplish this work entailed the suppression of the Mahdi's revolt, the strength of which he at first greatly underestimated. He had pressed strongly for the employment of Zobeir as "an absolute necessity for success" (3rd March); but this was refused, since Sir H. Gordon advised at this time that it would be dangerous. On 9th March General Gordon proposed, "if the immediate evacuation of Khartum is determined upon irrespective of outlying towns," to send down the "Cairo *employés*" and the garrison to Berber with Lieutenant-Colonel Stewart, to resign his commission, and to proceed with the stores and steamers to the Equatorial Provinces, which he would consider as placed under the King of the Belgians. On 13th March Lord Granville gave full power to General Gordon to "evacuate Khartum and save that garrison by conducting it himself to Berber without delay," and expressed a hope that he would not resign his commission.

***Relief expedition: question of route.***

By the end of March 1884 Sir E. Baring and the British officers in Egypt were convinced that force would have to be employed, and the growing danger of General Gordon, with the grave national responsibility involved, began to be realized in Great Britain. Sir Henry Gordon, however, who was in personal communication with Mr Gladstone, considered that his brother was in no peril, and for some time disbelieved in the need for a relief expedition. Meanwhile it was at least necessary to evolve some plan of action, and on 8th April the Adjutant-General addressed a memorandum to the Secretary of State for War detailing the measures required for placing 6500 British troops "in the neighbourhood of Shendi." The battle of the routes began much earlier, and was continued for some months. Practically the choice lay between the Nile and the Suakin–Berber road. The first involved a distance of 1650 miles from Cairo along a river strewn with cataracts, which obstructed navigation to all but small boats, except during the period of high water. So great was this obstruction that the Nile had never been a regular trade route to the Sudan. The second entailed a desert march of about 250 miles, of which one section, Obak–Bir Mahobeh (52 miles), was waterless, and the rest had an indifferent water supply (except at Ariab, about half-way to Berber), capable, however, of considerable development. From Berber the Nile is followed (210 miles) to Khartum. This was an ancient trade route with the Sudan, and had been used without difficulty by the reinforcements sent to Hicks Pasha in 1883, which were accompanied by guns on wheels. The authorities in Egypt, headed by General Stephenson, subsequently supported by the Admiral Lord John Hay, who sent a naval officer to examine the river as far as Dongola, were unanimous in favour of the Suakin–Berber route. From the first Major-General Sir A. Clarke, then Inspector-General of Fortifications, strongly urged this plan, and proposed to begin at once a metre gauge railway from Suakin, to be constructed by Indian labour under officers skilled in laying desert lines. Some preliminary arrangements were made, and on 14th June the Government sanctioned certain measures of preparation at Suakin. On the other side were the Adjutant-General (Lord Wolseley) and a small number of officers who had taken part in the Red River expedition of 1870. The memorandum of the Adjutant-General above referred to was based on the hypothesis that Khartum could not hold out beyond 15th November, and that the expedition should reach Berber by 20th October. Steamers were to be employed in such reaches as proved practicable, but the force was to be conveyed in special whale-boats, by which "the difficulty of transport is reduced to very narrow limits." The mounted force was to consist of 400 men on native horses and 450 men on horses or camels. The question of routes continued to be the subject of animated discussion, and on 29th July a committee of three officers who had served in the Red River expedition reported:—

> We believe that a brigade can easily be conveyed in small boats from Cairo to Dongola in the time stated by Lord Wolseley; and, further, that should it be necessary to send a still larger force by water to Khartum, that operation will present no insuperable difficulties.

***Lord Wolseley sent out; Nile route adopted.***

This most inconclusive report, and the baseless idea that the adoption of the Nile route would involve no chances of bloodshed, which the Government was anxious to avoid, seem to have decided the question. On 8th August the Secretary of State for War informed General Stephenson that "the time had arrived when some further measures for obtaining accurate information as to his (General Gordon's) position, and, if necessary, for rendering him assistance, should be adopted." General Stephenson still urged the Suakin–Berber route, and was informed on 26th August that Lord Wolseley would be appointed to take over the command in Egypt for the purposes of the expedition, for which a vote of credit had been taken in the House of Commons on 5th August. On 9th September Lord Wolseley arrived at Cairo, and the plan of operations was somewhat modified. A camel corps of 1100 men selected from twenty-eight regiments at home was added, and the "fighting force to be placed in line somewhere in the neighbourhood of Shendi" was fixed at 5400. The construction of whale-boats began on 12th August, and the first batch arrived at Wadi Halfa on 14th October, and on the 25th the first boat was hauled through the second cataract. The mounted forces proceeded up the banks, and the first half-battalion embarked at Gemai, 870 miles from Khartum, on 5th November, ten days before the date to which it had been assumed General Gordon could hold out. In a straggling procession the boats worked their way up to Korti, piloted by Canadian *voyageurs*. The labour was very great, and the troops, most of whom were having their first lesson in rowing, bore the privations of their unaccustomed conditions with admirable cheerfulness. By 25th December 2220 men had reached Korti, of whom about 800 only had been conveyed by the whale-boats, the last of which did not arrive till 27th January. Beyond Korti lay the very difficult section of the river to Abu Hamed, which was quite unknown. Meanwhile news of the loss of the *Abbas* and of the murder of Colonel J. D. Stewart and his party on 18th September had been received. A letter from Gordon, dated 4th November and received 17th November, stated that his steamers would await the expedition at Metemmeh, and added, "We can hold out forty days with ease; after that it will be difficult." In his diary, on 13th December, when his difficulties had become extreme, he noted that "if the expeditionary force does not come in ten days, the town may fall."

***Stewart's Desert Column; battle of Abu Klea wells.***

It was clear at Korti that something must be done at once; and on 13th December 1100 men, with 2200 camels, under Colonel Sir H. Stewart, were despatched to occupy Jakdul wells, 96 miles on the desert route to Metemmeh. Stewart returned on 5th January, and started again on the 8th, with orders to establish a fort at Abu Klea and to occupy Metemmeh. The "Desert Column," 1800 men, with 2880 camels in poor condition and 153 horses, found the enemy in possession of Abu Klea wells on the 16th, and was desperately attacked on the 17th. The

want of homogeneity of the force, and the unaccustomed tactics imposed upon the cavalry, somewhat hampered the defence, and the square was broken at the left rear corner. Driven back upon the camels in the centre, the troops fought hand to hand with the greatest gallantry. Order was quickly restored, and the attack was repulsed, with a loss of 74 killed and 94 wounded. At least 1100 of the enemy were killed. The wells being occupied and a zeriba formed, the column started on the evening of the 18th. The wrong road was taken, and great confusion occurred, during the night, but at dawn this was rectified; and after forming a rough fort under fire, by which Sir H. Stewart was fatally wounded, an advance was made at 3 p.m. The square was again heavily attacked, but the Arabs could not get to close quarters, and in the evening a bivouac was formed on the Nile. The British losses on this day were 23 killed and 98 wounded. The Desert Column was now greatly exhausted. On the 20th the village of Gubat was occupied; and on the following day Sir C. Wilson, on whom the command had devolved, advanced against Metemmeh, which was found too strong to assault. On this day General Gordon's four steamers arrived; and on the morning of the 24th Sir C. Wilson, with 20 British soldiers in red coats and about 280 Sudanese, started in the *Bordein* and *Telahawiyeh* for Khartum. The *Bordein* grounded on the following day, and again on the 26th, by which twenty-four hours were lost. At 11 a.m. on the 28th Khartum was sighted, and it soon became clear that the town was in the hands of the enemy. After reconnoitring farther, the steamers turned and proceeded down stream under a heavy fire, the Sudanese crews showing signs of disaffection. The *Telahawiyeh* was wrecked on 29th January and the *Bordein* on the 31st, Sir C. Wilson's party being rescued on 4th February by Lord C. Beresford in the *Safieh*, which had come up from Gubat on receipt of news carried there by Lieutenant Stuart Wortley in a row-boat. Khartum had been taken and General Gordon killed on the morning of 26th January 1885, having thus held out thirty-four days beyond the date when he had expected the end. The garrison had been reduced to starvation; and the arrival of twenty British soldiers, with orders to return at once, could not have affected the situation. The situation of the Desert Column and of its transport was most imperfectly understood at Korti, where impossible plans were formed. Fortunately Major-General Sir R. Buller, who arrived at Gubat on 11th February, decided upon withdrawal, thus averting impending disaster, and by 16th March the Desert Column had returned to Korti.

***Failure of relief expedition.***

The advance from Korti of the "River Column," under Major-General Earle, began on 28th December, and great difficulties of navigation were encountered. On 10th February an action was fought at Kirbekan with about 800 of the enemy, entailing a loss of 10 killed, including Major-General Earle, and 47 wounded. The column, now commanded by Brigadier-General Brackenbury, continued its slow advance, and on the morning of 24th February it was about 26 miles below Abu Hamed, a point where the Korosko desert route strikes the Nile, 350 miles from Khartum. Here it received orders to retire, and it reached Korti on 8th March.

***Suakin operations.***

The verbal message received from General Gordon on 30th December 1884 rendered the extreme danger of the position at Khartum painfully apparent, and the English Minister for War, acting on Sir E. Baring's advice, offered to make an active demonstration from Suakin. To this proposal Lord Wolseley demurred, but asked that ships of war should be sent to Suakin, and that "marines in red coats should be frequently landed and exercised." Lord Hartington replied that the Government did not consider that a demonstration of this kind could be effective, and again suggested stronger measures. On 8th January 1885 Lord Wolseley repeated that "the measures you propose will not assist my operations against Khartum," adding:—

> I have from first endeavoured to impress on Government that I am strong enough to relieve Khartum, and believe in being able to send a force, when returning by way of Berber, to Suakin, to open road and crush Osman Digna.

On this very day the small Desert Column started from Korti on its hazardous mission to the relief of a town fully 270 miles distant, held by a starving garrison, and invested by 30,000 fighting men, mostly armed with good rifles. Before reaching the Nile the Desert Column had lost 300 men and was unable to take Metemmeh, while its transport had completely broken down. On the 8th February Lord Wolseley telegraphed, "The sooner you can now deal with Osman Digna the better," and recommended the despatch of Indian troops to Suakin, to "co-operate with me in keeping road to Berber open." On 11th February, the day on which Sir R. Buller most wisely decided to withdraw the Desert Column from a position of extreme danger, it was determined at Korti that the River Column should proceed to attack Berber, and Lord Wolseley accepted the proposal of the Government to make a railway from Suakin, telegraphing to Lord Hartington:—

> By all means make railway by contract to Berber, or as far as you can, during summer. It will be invaluable as a means of supply, and I recommend it being begun immediately. Contract to be, if possible, for so much per ton military stores and supplies and men carried, per mile.

Every effort was now concentrated upon sending an expeditionary force to Suakin, and before the end of March about 13,000 men, including a brigade from India and a field battery from New South Wales, with nearly 7000 camels and 1000 mules, were there assembled. Lieutenant-General Sir G. Graham was placed in command of this force, with orders to break down the power of Osman Digna and to press the construction of the railway towards Berber. The troops at Suakin, on arrival, were much harassed by small night attacks, which ceased as soon as the scattered camps were drawn together. On 19th March Sir G. Graham, with the cavalry brigade and the infantry of the Indian contingent, reconnoitred as far as Hashin, finding the country difficult on account of the dense mimosa scrub. The enemy occupied the hills and fired upon the cavalry. On the 20th Sir G. Graham, with about 9000 men, again advanced to Hashin, and Dehilbat Hill was taken by the Berkshire Regiment and the Royal Marines. A squadron of the 9th Royal Lancers, which was dismounted in the thick bush, was driven back with the loss of 9 men; but elsewhere the Arabs never succeeded in closing, and the troops returned to Suakin in the afternoon, leaving the East Surrey Regiment in a zeriba covering some low hills near Hashin village. The total British loss was 9 killed and 39 wounded.

***Battle of Hashin.***

On 22nd March a force, consisting of two British and three Indian battalions, with a naval brigade, a squadron of Lancers, two companies of Engineers, and a large convoy of camels carrying water and supplies, under Major-General Sir J. McNeill, started from Suakin for Tamai, with orders to form a half-way zeriba. The advance was much impeded by the dense bush, and the force halted at Tofrik, about 6 miles out, at 10.30 a.m. A native had brought information that the enemy intended to attack while the zeriba was being formed, and

***McNeill's zeriba.***

this actually occurred. The force was caught partly unprepared soon after 2.30 p.m., and some fighting took place. The enemy were repulsed in about twenty minutes, the Naval Brigade, the Berkshire Regiment, the Royal Marines, and the 15th Sikhs showing the greatest gallantry. The casualties, including those among non-combatants, were 150 killed, 148 missing, and 174 wounded. More than 500 camels were killed. The tribesmen lost more than 1000 killed. As soon as firing was heard at Suakin, Sir G. Graham, with two battalions of Guards and a battery of Horse Artillery, started for Tofrik, but returned on being assured that reinforcements were not required. On the 24th and 26th convoys proceeding in square to Tofrik were attacked, the enemy being repulsed without difficulty. On 2nd April a force exceeding 7000 men, with 14 guns and 1600 transport animals, started from Suakin at 4.30 a.m., and bivouacked twelve hours later at Tesela Hill. Next morning an advance was made towards Tamai, and a number of huts in the Khor Ghob were burned. The force then returned to Suakin. The railway was now pushed on without interruption, reaching Otao on the 30th. On the night of 6th May a combined movement was made from Suakin and Otao, which resulted in the surprise and break-up of a force of the enemy under Mahommed Sardun, and the capture of a large number of sheep and goats. The moral effect of this operation was marked, and large numbers of tribesmen placed themselves unconditionally at the disposal of Sir G. Graham. A great native movement could now have been organized, which would have kept the route to Berber and enabled the railway to be rapidly pushed forward.

Meanwhile many communications had passed between the War Office and Lord Wolseley, who at first believed that Berber could be taken before the summer. In a long despatch of 6th March he discussed the general situation, and pointed out that although the force at his disposal "was amply sufficient" for raising the siege of Khartum and defeating the Mahdi, the conditions were changed by the fall of the town. It was now "impossible . . . to undertake any offensive operations until about the end of the summer," when twelve additional British battalions, four strong squadrons of British cavalry, and two R.H.A. batteries, together with a large extension of the Wadi Halfa railway, eleven steamers, and three hundred more whale-boats, would be required. He considered it necessary to hold Dongola, and he reported that he was "distributing this army along the left bank of the Nile, on the open reach of water" between the Hannek cataract and Abu Dom, opposite Merawi. On 30th March Lord Wolseley quitted the army and proceeded to Cairo. A cloud having arisen on the frontiers of Afghanistan, the withdrawal of the troops from the Sudan was ordered on 11th May. On the formation of Lord Salisbury's Cabinet, the new Secretary of State for War, Mr W. H. Smith, inquired whether the retirement could be arrested, but Major-General Sir R. Buller reported that the difficulties of reoccupation would be great, and that if Dongola was to be held, a fresh expedition would be required. On 20th June, before the British rearguard had left Dongola, the Mahdi died. The withdrawal of the Suakin force began on 17th May, and the friendly tribes, deprived of support, were compelled to make terms with Osman Digna, who was soon able to turn his attention to Kassala, which capitulated in August, nearly at the same time as Sennar.

***Political and military situation at end of operations.***

The failure of the operations in the Sudan had been absolute and complete, and the reason is to be sought in a total misconception of the situation, which caused vacillation and delay, and in the choice of a route by which, having regard to the date of the decision, the relief of General Gordon and Khartum was impossible.

(G. S. C.)

## Military Operations in Egypt and the Sudan. 1885 to 1896.

The operations against Mahdism during the eleven years from the end of the Nile expedition and the withdrawal from the Sudan to the commencement of the Dongola campaign will be more easily understood if, instead of narrating them in one chronological sequence, the operations in each province are considered separately. The Mahdi, Mahommed Ahmed, died at Omdurman on 22nd June 1885. He was succeeded by the principal Khalifa, Abdullah el Taaishi, a Baggara Arab, who for the next thirteen years ruled the Sudan with despotic power. Cruel, vicious, unscrupulous, and strong, the country groaned beneath his oppression. He removed all possible rivals, concentrated at Omdurman a strong military force composed of men of his own tribe, and maintained the ascendency of that tribe over all others. As the British troops retired to Upper Egypt, his followers seized the evacuated country, and the Khalifa cherished the idea, already formulated by the Mahdi, of the conquest of Egypt, but for some years he was too much occupied in quelling risings, massacring the Egyptians in the Sudan, and fighting Abyssinia, to move seriously in the matter.

*Upper Egypt.*—Mahommed el Kheir, dervish Emir of Dongola, however, advanced towards the frontier in the autumn, and at the end of November came in touch with the frontier field force, a body of some 3000 men composed in nearly equal parts of British and Egyptian troops. A month of harassing skirmishes ensued, during which the Egyptian troops showed their mettle at Mograkeh, where 200 of them held the fort against a superior number of dervishes, and in combats at Ambigol, Kosheh, and Firket. Sir Frederick Stephenson, commanding the British army of occupation in Egypt, then concentrated the frontier field force at Firket, and attacked the main body of the enemy at Ginnis on the 30th December 1885, completely defeating it and capturing two guns and twenty banners. It was here the new Egyptian army received its baptism of fire and acquitted itself very creditably. Although checked, the dervishes were not discouraged, and continued to press upon the frontier in frequent raids, and thus in many bloody skirmishes the fighting qualities of the Egyptian troops were developed. In April 1886 the frontier was drawn back to Wadi Halfa, a fortified camp at the northern end of the desolate defile, Batn-el-Hagar, through which the Nile tumbles amid black, rocky hills in a succession of rapids, and debouches on a wide plain. The protection of the frontier was now left in the hands of the Egyptian army, a British force remaining at Assuan, 200 miles to the north, as a reserve in case of emergency, and two years later even this precaution was deemed unnecessary.

In October 1886 Wad en Nejumi, the Emir who had defeated Hicks Pasha in Kordofan three years before, and led the assault at Khartum when General Gordon was slain in January 1885, replaced Mahommed el Kheir as "Commander of the Force for the Conquest of Egypt," and brought large reinforcements to Dongola. An advanced column under Nur-el Kanzi occupied Sarras in April 1887, was attacked by the Egyptian force under Colonel H. Chermside on the 28th of that month, and after a stubborn resistance was defeated with great loss. Nur-el-Kanzi was killed and ten standards taken.

The troubles in Darfur and with Abyssinia (*q.v.*) induced the Khalifa to reduce the garrisons of the north; nevertheless the dervishes reoccupied Sarras, continued

active in raids and skirmishes, and destroyed the railway south of Sarras, which during the Nile expedition of 1884 and 1885 had been carried as far as Akasheh. It was not until May 1889 that an invasion of the frontier on a large scale was attempted. At this time the power and prestige of the Khalifa were at their height: the rebellions in Darfur and Kordofan had been stamped out, the Anti-Mahdi was dead, and even the dervish defeat by the Abyssinians had been converted by the death of King John and the capture of his body into a success. It was therefore an opportune time to try to sweep the Turks and the British into the sea. On the 22nd June Nejumi was at Sarras with over 6000 fighting men and 8000 followers. On the 2nd July Colonel J. Woodhouse headed off a part of this force from the river at Argin and, after a sharp action, completely defeated it, killing 900, among whom were many important Emirs, and taking 500 prisoners and 12 banners, with very small loss to his own troops. A British brigade was on its way up stream, but the Sirdar, who had already arrived to take the command in person, decided not to wait for it. The Egyptian troops, with a squadron of the 20th Hussars, concentrated at Toski, and thence, on the 3rd August, General Grenfell, with slight loss, gained a decisive victory. Wad en Nejumi, most of his Emirs, and more than 1200 Arabs were killed; 4000 prisoners and 147 standards were taken, and the dervish army practically destroyed. No further serious attempts were made to disturb the frontier, of which the most southerly outpost was at once advanced to Sarras.

***Battle of Toski.***

The escape from Omdurman of Father Ohrwalder and of two of the captive nuns in December 1891, of Father Rossignoli in October 1894, and of Slatin Bey in February 1895, revealed the condition of the Sudan to the outside world, throw a vivid light on the rule of the Khalifa, and corroborated information already received of the discontent which existed among the tribes with the oppression and despotism under which they lived.

*The Eastern Sudan.*—In 1884 Colonel Chermside, Governor of the Red Sea Littoral, entered into arrangements with King John of Abyssinia for the relief of the beleaguered Egyptian garrisons. Gera, Amadib, Senhit, and Galabat were, in consequence, duly succoured, and their garrisons and Egyptian populations brought away to the coast by the Abyssinians in 1885. Unfortunately famine compelled the garrison of Kassala to capitulate on 30th July of that year, and Osman Digna hurried there from Tamai to raise a force with which to meet the Abyssinian general, Ras Alula, who was preparing for its relief. By the end of August Osman Digna had occupied Kufit, in the Barea country, with 10,000 men and entrenched himself. On the 23rd September Ras Alula attacked him there with an equal number of men and routed him with great slaughter. Over 3000 dervishes with their principal Emirs, except Osman Digna, lay dead on the field, and many more were killed in the pursuit. The Abyssinians lost 40 officers and 1500 men killed, besides many more wounded. Instead of marching on to Kassala, Ras Alula, who at this time was much offended by the transfer of Massawa by the Egyptians to Italy, made a triumphant entry into Asmara, and absolutely refused to make any further efforts to extricate Egyptian garrisons from the grip of the Khalifa. Meanwhile Osman Digna, who had fled from Kufit to Kassala, wreaked his vengeance upon the unhappy captives at Kassala.

In the neighbourhood of Suakin there were many tribes disaffected to the Khalifa's cause, and in the autumn of 1886 Colonel H. Kitchener, who was at the time Governor of the Red Sea Littoral, judiciously arranged a combination of them to overthrow Osman Digna, with the result that his stronghold at Tamai was captured on the 7th October, 200 of his men killed, and 50 prisoners, 17 guns, and a vast store of rifles and ammunition captured. For about a year there was comparative quiet. Then at the end of 1887 Osman Digna again advanced towards Suakin, but his force at Taroi was routed by the "Friendlies," and he fell back on Handoub. Kitchener unsuccessfully endeavoured to capture Osman Digna on the 17th January 1888, but in the attack was himself severely wounded, and was shortly after invalided. Later in the year Osman Digna collected a large force and besieged Suakin. In December the Sirdar arrived with reinforcements from Cairo, and on the 20th sallied out and attacked the dervishes in their trenches at Gemaizeh, clearing the whole line and inflicting considerable loss on the enemy, who retired towards Handoub, and the country was again fairly quiet for a time. During 1889 and 1890 Tokar became the centre of dervish authority, while Handoub continued to be occupied for the Khalifa. In January 1891 Osman Digna showed signs of increased activity, and Colonel Holled Smith, then Governor of the Red Sea Littoral, attacked Handoub successfully on the 27th and occupied it, then seized Trinkitat and Teb, and on the 19th February fought the decisive action of Afafit, occupied Tokar, and drove Osman Digna back to Temrin with a loss of 700 men, including all his chief Emirs. This action proved the final blow to the dervish power in the neighbourhood of Suakin, for although raiding continued on a small scale, the tribes were growing tired of the Khalifa's rule and refused to support Osman Digna.

***Battle of Afafit.***

In the spring of 1891 an agreement was made between England and Italy by which the Italian forces in Eritrea were at liberty, if they were able, to capture and occupy Kassala, which lay close to the western boundary of their new colony, on condition that they restored it to Egypt at a future day when required to do so. Three years passed before they availed themselves of this agreement. In 1893 the dervishes, 12,000 strong, under Ahmed Ali, invaded Eritrea, and were met on the 29th December at Agordat by Colonel Arimondi with 2000 men of a native force. Ahmed Ali's force was completely routed and himself killed, and in the following July Colonel Baratieri, with 2500 men, made a fine forced march from Agordat, surprised and captured Kassala on the 17th of that month, and continued to hold it for three years and a half.

*The Abyssinian Frontier.*—On the Abyssinian frontier Ras Adal was in command of a considerable force of Abyssinians early in 1886, and in June of that year he invaded Galabat and defeated the dervishes on the plain of Madana; the dervish Emir Mahommed Wad Ardal was killed and his camp captured. In the following year Emir Yunis ed Dekeim made two successful raids into Abyssinian territory, upon which Ras Adal collected an enormous army, said to number 200,000 men, for the invasion of the Sudan. The Khalifa sent Emir Hamdan Abu Angar, a very skilful leader, with an army of over 80,000 men against him. Abu Angar entered Abyssinia and, in August 1887, attacked Ras Adal in the plain of Debru Sin and, after a prolonged battle, defeated the Abyssinians, captured their camp, and marched on Gondar, the ancient capital of Abyssinia, which he sacked, and then returned into Galabat. King John, the Negus of Abyssinia, burning to avenge this defeat, marched, in February 1889, with an enormous army into Galabat, where the Emir Ez Zaki Tumal commanded the Khalifa's forces, some 60,000 strong, and had strongly fortified the town of Matamma and the camp. On the 9th March 1889 the Abyssinians made a terrific onslaught, stormed and burnt the town, and took thousands of prisoners. A small party of dervishes still held a zeriba when King John was struck by a stray bullet. The Ayssinians decided to retire, fighting ceased, and they moved off with their prisoners and the wounded Negus. That night the king died, and the greater part of the army having gone ahead with the prisoners, a party of Arabs pursued the rearguard, which consisted of the king's bodyguard, routed them, and captured the king's body, which was sent to Omdurman to confirm the report of a brilliant victory sent by Ez Zaki Tumal to the Khalifa. Internal strife prevented the new

Negus of Abyssinia from prosecuting the war, which thus, in spite of the Abyssinian success, resulted in the increased power and prestige of the Khalifa.

*Darfur and Kordofan.*—On the outbreak of the Mahdi's rebellion Slatin Bey was governor of the province, and when Madibbo, the insurgent Sheikh of Rizighat, attacked and occupied Shakka and was following up his success, Slatin twice severely defeated him and, having concentrated his forces at El Fasher, repulsed the enemy again at Om Shanga. Mahdism, however, spread over Darfur in spite of Slatin's efforts to stay it. He fought no fewer than twenty-seven actions in various parts of his province, but his own troops, in course of time, became infected with the new faith and deserted him. He was obliged to surrender at Dara in December 1883, and was a prisoner, first at Obeid and then at Omdurman, until he escaped in 1895. In January 1884 Zogal, the new dervish Emir of the province, attacked El Fasher, where Said Bey Guma and an Egyptian garrison 1000 strong with 10 guns was still holding out, and captured it. He also reduced the Jebel Marra district, where the loyal hill-people gave him some trouble.

After the death of the Mahdi in 1885, Madibbo revolted against the Khalifa, but was defeated by Karamalla, the dervish Emir of the Bahr-el-Ghazal, and was caught and executed. A war then sprang up between Karamalla and Sultan Yusef, who had succeeded Zogal as Emir of Darfur. Yusef was joined in 1887 by Sultan Zayid, the black ruler of Jebel Marra, and Karamalla's trusted general, Ketenbur, was defeated with great slaughter at El Towaish on 29th June 1887. Osman wad Adam (Ganu), Emir of Kordofan, was sent by the Khalifa to Karamalla's assistance. He forced back the Darfurians near Dara on the 26th December, routed Zayid in a second battle, entered El Fasher, and, in 1888, became complete master of the situation, the two Sultans being killed. The Darfurian chiefs then allied themselves with Abu Gemaizeh, Sheikh of the Masalit Arabs, who had proclaimed himself "Khalifa Osman," and was known as the Anti-Mahdi. The revolt assumed large proportions, and became the more dangerous to Abdullah, the Khalifa, by reason of its religious character, wild rumours spreading over the country and reaching to Egypt and Suakin of the advent to power of an opposition Mahdi. Abu Gemaizeh attacked a portion of Osman Adam's force, under Abd-el-Kader, at Kebkebieh, 30 miles from El Fasher, and almost annihilated it on the 16th October 1888; and a week later another large force of Osman Adam met with the same fate at the same place. Instead of following up his victories, Abu Gemaizeh retired to Dar Tama to augment his army, to which thousands flocked as the news of his achievements spread far and wide. He again advanced to El Fasher in February 1889, but was seized with smallpox. His army, however, under Fiki Adam, fought a fierce battle close to El Fasher on the 22nd, which resulted in its defeat and dispersion, and Abu Gemaizeh himself dying the following day, the movement collapsed.

In 1891 Darfur and Kordofan were again disturbed, and Sultan Abbas succeeded in turning the dervishes out of the Jebel Marra district. Two years later a saint of Sokoto, Abu Naal Muzil el Muhan, collected many followers and for a time threatened the Khalifa's power, but the revolt gradually died out.

*The Bahr-el-Ghazal.*—The first outbreak in favour of Mahdism in the Bahr-el-Ghazal took place at Liffi in August 1882, when the Dinka tribe, under Jango, revolted and was defeated by Lupton Bey with considerable slaughter at Tel Gauna, and again in 1883 near Liffi. In September of that year Lupton's captain, Rufai Aga, was massacred with all his men at Dembo, and Lupton, short of ammunition, was forced to retire to Dem Suliman, where he was completely cut off from Khartum. After gallantly fighting for eighteen months he was compelled by the defection of his troops to surrender on 21st April 1884 to Karamalla, the dervish Emir of the province. He died at Omdurman in 1888.

In 1890 the Shillouks in the neighbourhood of Fashoda rose against the Khalifa, and the dervish Emir of Galabat, Zeki Tumal, was engaged for two years in suppressing the rebellion. He got the upper hand in 1892, and was recalled to oppose an Italian force said to be advancing from Massawa; but on reporting that it was impossible to invade Eritrea, as the Khalifa wished him to do, he was summoned to Omdurman and put to death. The country then relapsed into its original barbarous condition, and dervish influence was nominal only. In 1892 the Congo State Expedition established posts up to the seventh parallel of north latitude. In 1893 the dervish Emir, Abu Mariam, fought with the Dinka tribe and was killed and his force destroyed, the fugitives taking refuge in Shakka. In the following year the Congo Expedition established further posts, and in consequence the Khalifa sent 3000 men, under the Emir Khatem Musa, from Skakka to reoccupy the Bahr-el-Ghazal. The Belgians at Liffi retired before him, and he entered Faroga. Famine and disease broke out in Khatem Musa's camp in 1895, and a retreat was made towards Kordofan.

*Equatoria.*—In the equatorial province, which extended from the Albert Nyanza to Lado, Emin Bey, who had a force of 1300 Egyptian troops and 3000 irregulars, distributed among many stations, held out, hoping for reinforcements. In March 1885, however, Amadi fell to the dervishes, and on the 18th April Karamalla arrived near Lado, the capital, and sent to inform Emin of the fall of Khartum. Emin and Captain Casati, an Italian, moved south to Wadelai, giving up the northern posts, and opened friendly relations with Kabarega, King of Unyoro. On 26th February 1886 Emin received despatches from Cairo *viâ* Zanzibar, from which he learned all that had occurred during the previous three years, and that "he might take any step he liked, should he decide to leave the country." He determined to remain where he was and "hold together, as long as possible, the remnant of the last ten years." His troops were in a mutinous state, wishing to go north rather than south, as Emin had ordered them to do, and unsuccessfully endeavoured to carry him with them by force.

His communications to Europe through Zanzibar led to the Relief Expedition under Mr H. M. Stanley, which went to his rescue by way of the Congo in 1887, and after encountering incredible dangers and experiencing innumerable sufferings, met with Emin and Casati at Nsabé, on the Albert Nyanza, on 29th April 1888. Stanley went back in May to pick up his belated rearguard, leaving Mounteney Jephson and a small escort to accompany Emin round his province. The southern garrisons decided to go with Emin, but the troops at Laboreh mutinied, and a general revolt broke out, headed by Fadl el Maula, governor of Fabbo. On arriving at Dufileh in August 1888, Emin and Jephson were made prisoners by the Egyptian mutineers. In the meantime the arrival of Stanley at Lake Albert had caused rumours, which quickly spread to Omdurman, of a great invading White Pasha, with the result that in July the Khalifa sent up the river three steamers and six barges, containing 4000 troops, to oppose this new-comer. In October Omar-Saleh, the Mahdist commander, took Rejaf and sent messengers to Dufileh to summon Emin to surrender; but on the 15th November the mutineers released both Emin and Jephson, who returned to Lake Albert with some 600 refugees, and joined Stanley in February 1889. The expedition arrived at Zanzibar at the end of the year.

Emin's mutinous troops kept the dervishes at bay between Wadelai and Rejaf, and eventually severely defeated them, driving them back to Rejaf. They did not, however, follow up their victory, and under the leadership of Fadl-el-Maula Bey remained about Wadelai, while the dervishes strengthened their post at Rejaf. In 1893 Fadl-el-Maula Bey and many of his men took service with Baert of the Congo State Expedition. The Bey was killed fighting the dervishes at Wandi in January 1894, and the remnant of his men eventually were found by Captain Thruston from Uganda on the 23rd March 1894 at Mahaji Sghir, on the Albert Nyanza, whither they had drifted from Wadelai in search of supplies. They were enlisted by Thruston and brought back under the British flag to Uganda.

In consequence of the Franco-Congolese Treaty of 1894, Major Cunningham and Lieutenant Vandeleur were sent from Uganda to Dufileh, where they planted the British flag on the 15th January 1895.

### Sudan Operations, 1896–99.

The wonderful progress — political, economical, and social—which Egypt had made during British occupation, so ably set forth in Sir Alfred Milner's *England in Egypt* (published in 1892), together with the revelation in so strong a light of the character of the Khalifa's despotism in the Sudan and the miserable condition of his misgoverned people, as detailed in the accounts of their captivity at Omdurman by Father Ohrwalder and Slatin Bey (published in 1892 and 1896), stirred public opinion in Great Britain, and brought the question of the recovery of the Sudan into prominence. A change of ministry took place in 1895, and Lord Salisbury's Cabinet, which had consistently assailed the Egyptian policy of the old, was not unwilling to consider whether the flourishing condition of Egyptian finance, the prosperity of the country and the settled state of its affairs, with a capable and proved little army ready to hand, did not warrant an attempt being made to recover gradually the Sudan provinces abandoned by Egypt in 1885 on the advice of Mr Gladstone's Government.

***Dongola campaign, 1896.***

Such being the condition of public and official sentiment, the crushing defeat of the Italians by the Abyssinians at the battle of Adowa on 1st March 1896, and the critical

state of Kassala—held by Italy at British suggestion, and now closely invested by the dervishes—made it not only desirable but necessary to take immediate action.

On the 14th March 1896 Major-General Sir H. Kitchener, who succeeded Sir Francis Grenfell as Sirdar of the Egyptian army in 1892, received orders to reoccupy Akasheh, 50 miles south of Sarras, and to carry the railway on from Sarras. Subsequent operations were to depend upon the amount of resistance he encountered. On the 20th March Akasheh was occupied without opposition by an advanced column of Egyptian troops under Major J. Collinson, who formed an entrenched camp there. The reserves of the Egyptian army were called out, and responded with alacrity. The troops were concentrated at Wadi Halfa; the railway reconstruction, under Lieutenant E. P. Girouard, R.E., pushed southward; and a telegraph line followed the advance. At the commencement of the campaign the Egyptian army, including reserves, consisted of 16 battalions of infantry, of which 6 were Sudanese, 10 squadrons of cavalry, 5 batteries of artillery, 3 companies of garrison artillery, and 8 companies of camel corps, and it possessed 13 gunboats for river work. Colonel L. Rundle was Chief of the Staff; Major R. Wingate was head of the Intelligence Department, with Slatin Bey as his assistant; and Colonel A. Hunter was in command of Sarras, and south. The 1st battalion of the North Staffordshire Regiment moved up from Cairo to join the Egyptian army.

In the meantime the advance to Akasheh had already relieved the pressure at Kassala, Osman Digna having withdrawn a considerable force from the investing army and proceeded with it to Suakin. To meet Osman Digna's movement Lieutenant-Colonel G. E. Lloyd, the Suakin commandant, advanced to the Taroi Wells, nineteen miles south of Suakin, on the 15th April to co-operate with the "Friendlies," and with Major H. M. Sidney, advancing with a small force from Tokar. His cavalry, under Major Fenwick, went out to look for Sidney's force, and were surprised by a large number of dervishes. Fenwick, with some 40 officers and men, seized an isolated hill and held it through the night, repulsing the dervishes, who were the same night driven back with such heavy loss in attacking Lloyd's zeriba that they retired to the hills, and comparative quiet again reigned at Suakin. At the end of May an Indian brigade arrived for garrison duty, and the Egyptian troops were released for service on the Nile.

The dervishes first came in contact with the Egyptian cavalry on the Nile near Akasheh, on the 1st May, and were repulsed. The army concentrated at Akasheh early in June, and on the 6th Kitchener moved to the attack of Firket, 16 miles away, where the Emir Hamuda, with 3000 men, was encamped. The attack was made in two columns: one, under Colonel Hunter, marching along the river-bank, approached Firket from the north; while the other, under Major Burn-Murdoch, making a detour through the desert, approached it from the south. The co-operation of the two columns was admirably timed, and on the morning of the 7th the dervish camp was surrounded, and, after a sharp fight, Hamuda and many emirs and about 1000 men were killed and 500 prisoners taken. The dash and discipline of the Egyptian troops in this victory were a good augury for the future.

By the end of June the railway was advanced beyond Akasheh, and headquarters were at Kosheh, 10 miles farther south. Cholera and fever were busy both with the North Staffordshire Regiment at Gemai, whither they had been moved on its approach, and with the Egyptian troops at the front, and carried off many officers and men. The railway reached Kosheh early in August; the cholera disappeared, and stores were collected and arrangements steadily made for a farther advance. The North Staffordshire moved up to the front, and in September the army moved on Kerma, which was found to be evacuated, the dervishes having crossed the river to Hafir. There they were attacked by the gunboats and Kitchener's artillery from the opposite bank, and forced to retire, with their commander, Wad Bishara, seriously wounded. Dongola was bombarded by the gunboats and captured by the army on the 23rd September. Bishara and his men retreated, but were pursued by the Egyptians until the retreat became a hopeless rout. Guns, small arms, and ammunition, with large stores of grain and dates, were captured, many prisoners taken, while hundreds surrendered voluntarily, among them a brother of the Emir Wad en Nejumi. The dervish Dongola army had practically ceased to exist. Debbeh was seized on the 3rd October, Korti and Merawi occupied soon after, and the principal sheiks came in and submitted to the Sirdar. The Dongola campaign was over, and the province recovered to Egypt. The Indian brigade at Suakin returned to India, and was replaced by Egyptians. The North Staffordshire returned to Cairo. The work of consolidation began, and preparations were made for a farther advance when everything should be ready.

The railway up the right bank of the Nile was continued to Kermah, in order to evade the difficulties of the 3rd Cataract; but the Sirdar had conceived the bold project of cutting off the great angle of the Nile from Wadi Halfa to Abu Hamed, involving nearly 600 miles of navigation and including the Fourth Cataract, by

***The Sudan campaign, 1897.***

constructing a railway across the Nubian desert, and so bringing his base at Wadi Halfa within a few hours of his force, when it should have advanced to Abu Hamed, instead of ten days. Early in 1897 this new line of railway was commenced from Wadi Halfa across the great Nubian desert 230 miles to Abu Hamed. The first-mentioned line reached Kerma in May, and by July the second had advanced 130 miles into the desert towards Abu Hamed, when it became necessary, before it was carried farther, to secure that terminus by an advance from Merawi.

In the meantime the Khalifa was not idle. He occupied Abu Klea wells and Metemmeh; recalled the Emir Ibrahim Khalil, with 4000 men, from the Ghezira; brought to Omdurman the army of the west under Mahmud—some 10,000 men; entrusted the line of the Atbara—Ed Damer, Adarama, Asubri, and El Fasher—to Osman Digna; constructed defences in the Shabluka Gorge; and personally superintended the organization and drill of the forces gathered at Omdurman, and the collection of vast stores of food and supplies of camels for offensive expeditions.

Towards the end of June the chief of the Jaalin tribe, Abdalla wad Said, who occupied Metemmeh, angered by the Khalifa, made his submission to Kitchener and asked for support, at the same time foolishly sending a defiant letter to the Khalifa. The Sirdar sent him rifles and ammunition across the desert from Korti; but before they arrived, Mahmud's army, sent by the Khalifa, swept down on Metemmeh on 1st July and massacred Abdalla wad Said and his garrison.

On the 29th July, after several reconnaissances, Major-General Hunter, with a flying column, marched up the Nile from near Merawi to Abu Hamed, 133 miles distant, along the edge of the Monassir desert. He arrived on 7th August and captured it by storm, the dervishes losing 250 killed and 50 prisoners. By the end of the month the gunboats had surmounted the Fourth Cataract and reached Abu Hamed. Berber was found to be deserted, and occupied by Hunter on the 5th September, and in the

following month a large force was entrenched there. The Khalifa, fearing an attack on Omdurman, moved Osman Digna from Adarama to Shendi. On the 23rd October Hunter, with a flying column lightly equipped, left Berber for Adarama, which he burned on the 2nd November, and after reconnoitring for 40 miles up the Atbara, returned to Berber. The Nile was falling, and Kitchener decided to keep the gunboats above the impassable rapid at Um Tuir, 4 miles north of the confluence of the Atbara with the Nile, where he constructed a fort. The gunboats made repeated reconnaissances up the river, bombarding Metemmeh with effect. The railway reached Abu Hamed on the 4th November, and was pushed rapidly forward along the right bank of the Nile towards Berber.

The forces of the Khalifa remaining quiet, the Sirdar visited Kassala and negotiated with the Italian General Caneva for its restoration to Egypt. The Italians were anxious to leave it; and on Christmas Day 1897 Colonel Parsons, with an Egyptian force from Suakin, took it formally over, together with a body of Arab irregulars employed by the Italians. These troops were at once despatched to capture the dervish posts at Asabri and El Fasher, which they did with small loss.

On his return from Kassala to Berber the Sirdar received information of an intended advance of the Khalifa northward. He at once ordered a concentration of Egyptian troops towards Berber, and telegraphed to Cairo for a British brigade. By the end of January the concentration was complete, and the British brigade, under Major-General Gatacre, was at Dakhesh, south of Abu Hamed. Disagreement among the Khalifa's generals postponed the dervish advance and gave Kitchener much-needed time. But at the end of February, Mahmud crossed the Nile to Shendi with some 12,000 fighting men, and with Osman Digna advanced along the right bank of the Nile to Aliab, where he struck across the desert to Nakheila, on the Atbara, intending to turn Kitchener's left flank at Berber. The Sirdar took up a position at Ras el Hudi, on the Atbara. His force consisted of Gatacre's British brigade (1st Warwicks, Lincolns, Seaforths, and Camerons) and Hunter's Egyptian division (3 brigades under Colonels Maxwell, MacDonald, and Lewis respectively), Broadwood's cavalry, Tudway's camel corps, and Long's artillery. The dervish army reached Nakheila on the 20th March, and entrenched themselves there in a formidable zeriba. After several reconnaissances, in which fighting took place with Mahmud's outposts, it was ascertained from prisoners that their army was short of provisions and that great leakage was going on. Kitchener, therefore, did not hurry. He sent his flotilla up the Nile and captured Shendi, the dervish depôt, on the 27th March. On the 4th April he advanced to Abadar. A final reconnaissance was made on the 5th. On the following day he bivouacked at Umdabia, where he constructed a strong zeriba, which was garrisoned by an Egyptian battalion, and on the night of the 7th he marched to the attack of Mahmud's zeriba, which, after an hour's bombardment on the morning of the 8th April, was stormed with complete success. Mahmud and several hundred dervishes were captured, 40 emirs and 3000 Arabs killed, and many more wounded; the rest escaped to Gedaref. The Sirdar's casualties were 80 killed and 472 wounded.

*Sudan campaign, 1898.*

Preparations were now made for the attack on the Khalifa's force at Omdurman; and in the meantime the troops were camped in the neighbourhood of Berber, and the railway carried on to the Atbara. At the end of July reinforcements were forwarded from Cairo; and on the 24th August the following troops were concentrated for the advance at Wad Hamad, above Metemmeh, on the western bank of the Sixth Cataract:—British division, under Major-General Gatacre, consisting of 1st Brigade, commanded by Colonel H. G. Wauchope (1st Warwicks, Lincolns, Seaforths, and Camerons), and 2nd Brigade, commanded by Colonel the Hon. N. G. Lyttelton (1st Northumberlands and Grenadier Guards, 2nd Lancashire and Rifle Brigade); Egyptian division, under Major-General Hunter, consisting of four brigades, commanded by Colonels MacDonald, Maxwell, Lewis, and Collinson; mounted troops — 21st Lancers, Camel Corps, and Egyptian Cavalry; artillery, under Colonel Long, 2 British batteries, 5 Egyptian batteries, and 20 machine guns; detachment of Royal Engineers. The flotilla, under Commander Keppel, R.N., consisted of 10 gunboats and 5 transport steamers. The total strength was nearly 26,000 men.

While the army moved along the west bank of the river, a force of Arab irregulars or "Friendlies" marched along the east bank, under command of Major Stuart-Wortley and Lieutenant Wood, to clear it of the enemy as far as the Blue Nile; and on the 12th September the gunboats bombarded the forts on both sides of the river and breached the great wall of Omdurman. Kitchener met with no opposition; and on the 1st September the army bivouacked in zeriba at Egeiga, on the west bank of the Nile, within 4 miles of Omdurman. Here, on the morning of the 2nd September, the Khalifa's army, 40,000 strong, attacked the zeriba, but was repulsed with slaughter. Kitchener then moved out and marched towards Omdurman, when he was again twice fiercely attacked on the right flank and rear, MacDonald's brigade bearing the brunt. MacDonald distinguished himself by his tactics, and completely repulsed the enemy. The 21st Lancers gallantly charged a body of 2000 dervishes which was unexpectedly met in a khor on the left flank, and drove them westward, the Lancers losing a fifth of their number in killed and wounded. The Khalifa was now in full retreat, and the Sirdar, sending his cavalry in pursuit, marched into Omdurman. The dervish loss was over 10,000 killed, as many wounded, and 5000 prisoners. The Khalifa's black flag was captured and sent home to the Queen. The British and Egyptian casualties together were under 500. The European prisoners of the Khalifa found in Omdurman—Charles Neufeld, Joseph Ragnotti, Sister Teresa Grigolini, and some 30 Greeks—were released; and on Sunday the 4th September the Sirdar, with representatives from every regiment, crossed the river to Khartum, where the British and Egyptian flags were hoisted, and a short service held in memory of General Gordon, near the place where he met his death.

*Battle of Omdurman.*

The results of the battle of Omdurman were the practical destruction of the Khalifa's army, the extinction of Mahdism in the Sudan, and the recovery of nearly all the country formerly under Egyptian authority.

The Khalifa fled with a small force to Obeid in Kordofan. The British troops were quickly sent down stream to Cairo, and the Sirdar, shortly afterwards created Lord Kitchener of Khartum, was free to turn his attention to the reduction of the country to some sort of order.

He had first, however, to deal with a somewhat serious matter—the arrival of a French expedition at Fashoda, on the White Nile, some 600 miles above Khartum. He started for the south on the 10th September, with 5 gunboats and a small force, dispersed a body of 700 dervishes at Reng on the 15th, and four days later arrived at Fashoda, to find the French Captain Marchand, with 120 Senegalese soldiers, entrenched there and the French flag flying. He arranged with Marchand to leave the political question to be settled

*Captain Marchand at Fashoda.*

by diplomacy, and contented himself with hoisting the British and Egyptian flags to the south of the French flag, and leaving a gunboat and a Sudanese battalion to guard them. He then steamed up the river and established a post at Sobat; and after sending a gunboat up the Bahr-el-Ghazal to establish another post at Meshra-er-Rek, he returned to Omdurman. The French expedition had experienced great difficulties in the swampy region of the Bahr-el-Ghazal, and had reached Fashoda on the 10th July. It had been attacked by a dervish force on the 25th August, and was expecting another attack when Kitchener arrived and probably saved it from destruction. The Fashoda incident was the subject of important diplomatic negotiations, which at one time approached an acute phase; but ultimately the French position was found to be untenable, and on 11th December Marchand and his men returned to France by the Sobat, Abyssinia, and Jibuti. In the following March the spheres of interest of Great Britain and France in the Nile basin were defined by a declaration making an addition to Article IV. of the Niger Convention of the previous year.

During the Sirdar's absence from Omdurman Colonel Hunter commanded an expedition up the Blue Nile, and by the end of September had occupied and garrisoned Wad Medina, Sennar, Karkoj, and Roseires. In the meantime Colonel Parsons marched with 1400 men from Kassala on the 7th September, to capture Gedaref. He encountered 4000 dervishes under Emir Saadalla outside the town, and after a desperate fight, in which he lost 50 killed and 80 wounded, defeated them and occupied the town on the 22nd. The dervishes left 500 dead on the field, among whom were four emirs. Having strongly entrenched himself, Parsons beat off, with heavy loss to the dervishes, two impetuous attacks made on the 28th by Ahmed Fedil. But the garrison of Gedaref suffered from severe sickness, and Colonel Collinson was sent to their aid with reinforcements from Omdurman. He steamed up the Blue Nile and the Rahad river to Ain-el-Owega, whence he struck across the desert, reaching Gedaref on the 21st October, to find that Ahmed Fedil had gone south with his force of 5000 men towards Roseires. Colonel Lewis, who was at Karkoj with a small force, moved to Roseires, where he received reinforcements from Omdurman, and on the 26th December caught Ahmed Fedil's force as it was crossing the Blue Nile at Dakheila, and after a very severe fight cut it up. The dervish loss was 500 killed, while the Egyptians had 24 killed and 118 wounded. Two thousand five hundred fighting men surrendered later, and the rest escaped with Ahmed Fedil to join the Khalifa in Kordofan.

***Operations in the Sudan, 1899.***

On the 25th January 1899 Colonel Walter Kitchener was despatched by his brother, in command of a flying column of 2000 Egyptian troops and 1700 Friendlies, which had been concentrated at Faki Kohi, on the White Nile, some 200 miles above Khartum, to reconnoitre the Khalifa's camp at Sherkela, 130 miles west of the river, in the heart of the Baggara country in Kordofan, and if possible to capture it. The position was found to be a strong one, occupied by over 6000 men; and as it was not considered prudent to attack it with an inferior force at such a distance from the river base, the flying column returned. No further attempt was made to interfere with the Khalifa in his far-off retreat until towards the end of the year, when, good order having been generally established throughout the rest of the Sudan, it was decided to extend it to Kordofan.

In the autumn of 1899 the Khalifa was at Jebil Gedir, a hill in Southern Kordofan, about 80 miles from the White Nile, and was contemplating an advance. Lord Kitchener concentrated 8000 men at Kaka, on the river, 380 miles south of Khartum, and moved inland on the 20th October. On arriving at Fongor it was ascertained that the Khalifa had gone north, and the cavalry and camel corps having reconnoitred Jebil Gedir, the expedition returned. On the 13th November the Emir Ahmed Fedil debouched on the river at El Alub, but retired on finding Colonel Lewis with a force in gunboats. Troops and transport were then concentrated at Faki Kohi, and Colonel Wingate sent with reinforcements from Khartum to take command of the expedition and march to Gedid, where it was anticipated the Khalifa would be obliged to halt. A flying column, comprising a squadron of cavalry, a field battery, 6 machine guns, 6 companies of the Camel Corps, and a brigade of infantry and details, in all 3700 men, under Wingate, left Faki Kohi on the 21st November. The very next day he encountered Ahmed Fedil at Abu Aadel, drove him from his position with great loss, and captured his camp and a large supply of grain he was convoying to the Khalifa. Gedid was reached on the 23rd, and the Khalifa was ascertained to be at Om Dubreikat. Wingate marched at midnight of the 24th, and was resting his troops on high ground in front of the Khalifa's position, when at daybreak of the 25th his picquets were driven in, and the dervishes attacked. They were repulsed with great slaughter, and Wingate advancing, carried the camp. The Khalifa Abdullah el Taaishi, unable to rally his men, gathered many of his principal emirs around him, among whom were his sons and brothers, Ali Wad Helu, Ahmed el Fedil, and other well-known leaders, and they met their death unflinchingly from the bullets of the advancing Sudanese infantry. Three thousand men and 29 emirs of importance, including Sheik-ed-din, the Khalifa's eldest son and intended successor, surrendered. The dervish loss in the two actions was estimated at 1000 killed and wounded, while the Egyptian casualties were only 4 killed and 29 wounded. Thus ended the power of the Khalifa and of Mahdism.

***Death of the Khalifa.***

On the 19th January 1900 Osman Digna, who had been so great a supporter of Mahdism in the Eastern Sudan, and had always shown great discretion in securing the safety of his own person, was surrounded and captured at Jebel Warriba, as he was wandering a fugitive among the hills beyond Tokar.

The reconquest of Dongola and the Sudan provinces during the three years from March 1896 to December 1898, considering the enormous extent and difficulties of the country, was achieved at an unprecedentedly small cost, while the main item of expenditure—the railway—remains a permanent benefit to the country. The figures are:[1]—

| | |
|---|---|
| Railways | £E.1,181,372 |
| Telegraphs | 21,825 |
| Gunboats | 154,934 |
| Military | 996,223 |
| Total | £E.2,354,354 |

The railway, delayed by the construction of the big bridge over the Atbara, was opened to the Blue Nile opposite Khartum, 187 miles from the Atbara, at the end of 1899. (R. H. V.)

**Egyptology.**—Since 1880 the appearance of almost every part of Egyptology has been changed. In the history, the kings who used to be thought mythical are now as well known as those of late times, and the long prehistoric age is better known than that of any other country. In the archæology, total ignorance is now replaced by an accurate discrimination of the ages of all the usual manufactures. In the language, the guess-work

[1] See Lord Cromer's Report, dated at Cairo, 26th February 1899.

of earlier times has faded before elaborate grammatical studies, which formulate a great deal more than the Egyptians themselves knew about their own writing.

### History.

The earliest stage of man that is known in Egypt is the Palæolithic; this was contemporary with a rainy climate, which enabled at least some vegetation to grow on the high desert, for the great bulk of the worked flints are found 500–1500 ft. above the Nile, on a table-land which is now entirely barren desert. Water-worn palæoliths are found in the beds of the stream courses, now entirely dried up, and flaked flints of a rather later style occur in the deep beds of Nile gravels, which are 20 or 30 ft. above the highest level of the present river. This type of work, however, lasted on to the age of the existing conditions, for perfectly sharp and fresh palæoliths are found on the desert as low down as the present high Nile.

The date of the change of climate is roughly shown by the depth of the Nile deposits. It is well known, by a scale extending over about 3000 years, that in different parts of Egypt the rise of the Nile bed has been on an average about 4 inches per century, owing to the annual deposits of mud during the inundation (7) (23).* And in various borings that have been made, the depth of the Nile mud is only about 25 or 30 ft. (7). Hence an age of about 8000 or 9000 years for the cultivable land may be taken as a minimum, probably to be somewhat extended by slighter deposit in the earlier time.

The continuous history extends to about 5000 B.C., and the prehistoric age of continuous culture known to us covers probably 2000 years more; hence our continuous knowledge probably extends back to about 7000 B.C., or to about the time when the change of climate took place. At that time we find a race of European type starting on a continuous career, but with remains of a steatopygous race of "Bushman" (Koranna) type known and represented in modelled figures (8). We can hardly avoid the conclusion that this steatopygous race was that of Palæolithic man in Egypt, especially as that equivalence is also known in the French cave remains. It is noticeable that all the figures known of this race—in France, Malta, and Egypt—are women, suggesting that the men were exterminated by the newer people, but the women were kept as slaves, and hence were familiar to the pioneers of the European race. These Palæolithic women were broadly built, with deep lumbar curve, great masses of fat on the hips and thighs, with hair along the lower jaw and over most of the body.

The fresh race which entered Egypt was of European type—slender, fair-skinned, with long wavy brown hair. The skull was closely like that of the ancient and modern Algerians of the interior; and as one of the earliest classes of their pottery is similar in material and decoration to the present Kabyle pottery, we may consider them a branch of Algerians (8). They seem to have entered the country as soon as the Nile deposits rendered it habitable by an agricultural people. They already made well-formed pottery by hand, knew copper as a rarity, and were clad in goat-skins (9). Entering a fertile country, and mixing probably with the earlier race, they made a rapid advance in all their products, and in a few generations they had an able civilization. Their work in flint was fine and bold, with more delicate handiwork than that of any other people except their descendants; their stone vases were cut in the hardest materials with exquisite regularity; their carving of ivory and slate was better than anything which followed for over a thousand years; and they had a large number of signs in use, which were probably the first stages of our alphabet (12).

After some centuries of this culture a change appears, at the same point of time in every kind of work. A difference of people seems probable, but no great change of race, as the type is unaltered. The later people show some Eastern affinities; and it seems as if a part of the earlier Libyan people had entered Syria or North Arabia and had afterwards flowed back through Egypt, modified by their Semitic contact. It is perhaps to this influx that the Semitic element in the Egyptian language is due.

This later prehistoric people brought in new kinds of pottery and more commerce, which provided gold, silver, and various foreign stones; they also elaborated the art of flint-working to its highest pitch of regularity and beauty, and they greatly extended the use of copper, and developed the principal tools to full size (9). But they show even less artistic feeling than the earlier branch, for all figure-carving quickly decayed, both in ivory and in stone. The use of amulets was brought in, and also forehead-pendants of shell. And the signs which were already in use almost entirely disappeared. (See Fig. 1.)

In the earlier, and still more in the later, age, ships or galleys rowed by oars were familiar; and these were sometimes of large size, figured with sixty oars. That commerce was already carried on in the Mediterranean is shown by the foreign pottery imported into Egypt, even before the middle of the prehistoric age; by the supply of gold in the Ist Dynasty, apparently from Asia Minor, and by the pottery of the Ægean being brought in at the same time (12).

This prehistoric civilization was much decayed when it was overcome by a new influx of people, who founded the dynastic rule. These came apparently from the Red Sea, as they entered Egypt in the region of Koptos, and not either from the north or from the Upper Nile. They were a highly artistic people, as the earliest works attributable to them—the Min sculptures at Koptos—show better drawing (Plate, Fig. 2) than any work by the older inhabitants (11); and they rapidly advanced in art to the noble works of the Ist Dynasty. They also brought in the hieroglyphic system, which was developed along with their art. It seems probable that they came up from the Land of Pun, at the south of the Red Sea, and they may have been a branch of the Punic race in its migration from the Persian Gulf round by sea to the Mediterranean. They rapidly subdued the various tribes who were in Egypt, and at least five different types of man are shown on the monuments of their earliest kings. The oldest records are those sculptured in relief on the palettes of slate, which show the battles, conquests, and triumphs of the dynastic race, culminating in the great palette of King Narmer (Fig. 2), who seems to have reigned very shortly before Menes (10). These kings seem to be the dynasty of 10 kings of Thinis (Abydos) who reigned for 350 years, according to Manetho. The names recovered which appear to belong to them are Ka, Zeser, Nar-mer, and Sma: of Narmer a magnificent slate with triumphal carvings was found at Hierakonpolis (10).

The completion of the conquest of Egypt led to Men (Mena, Menes) being called the founder of the Ist Dynasty (Fig. 3). And this period, which has often been supposed fabulous, is now as well known to us as most of the later dynasties, owing to the study of the inscriptions and remains from the royal tombs of Abydos (12). The early dynasties have hitherto been known only by the list of kings carved in the XIXth Dynasty at Abydos by Sety I., and by the Greek transcription of Manetho. We now have recovered the original forms

* Reference numbers refer to list of books at the end.

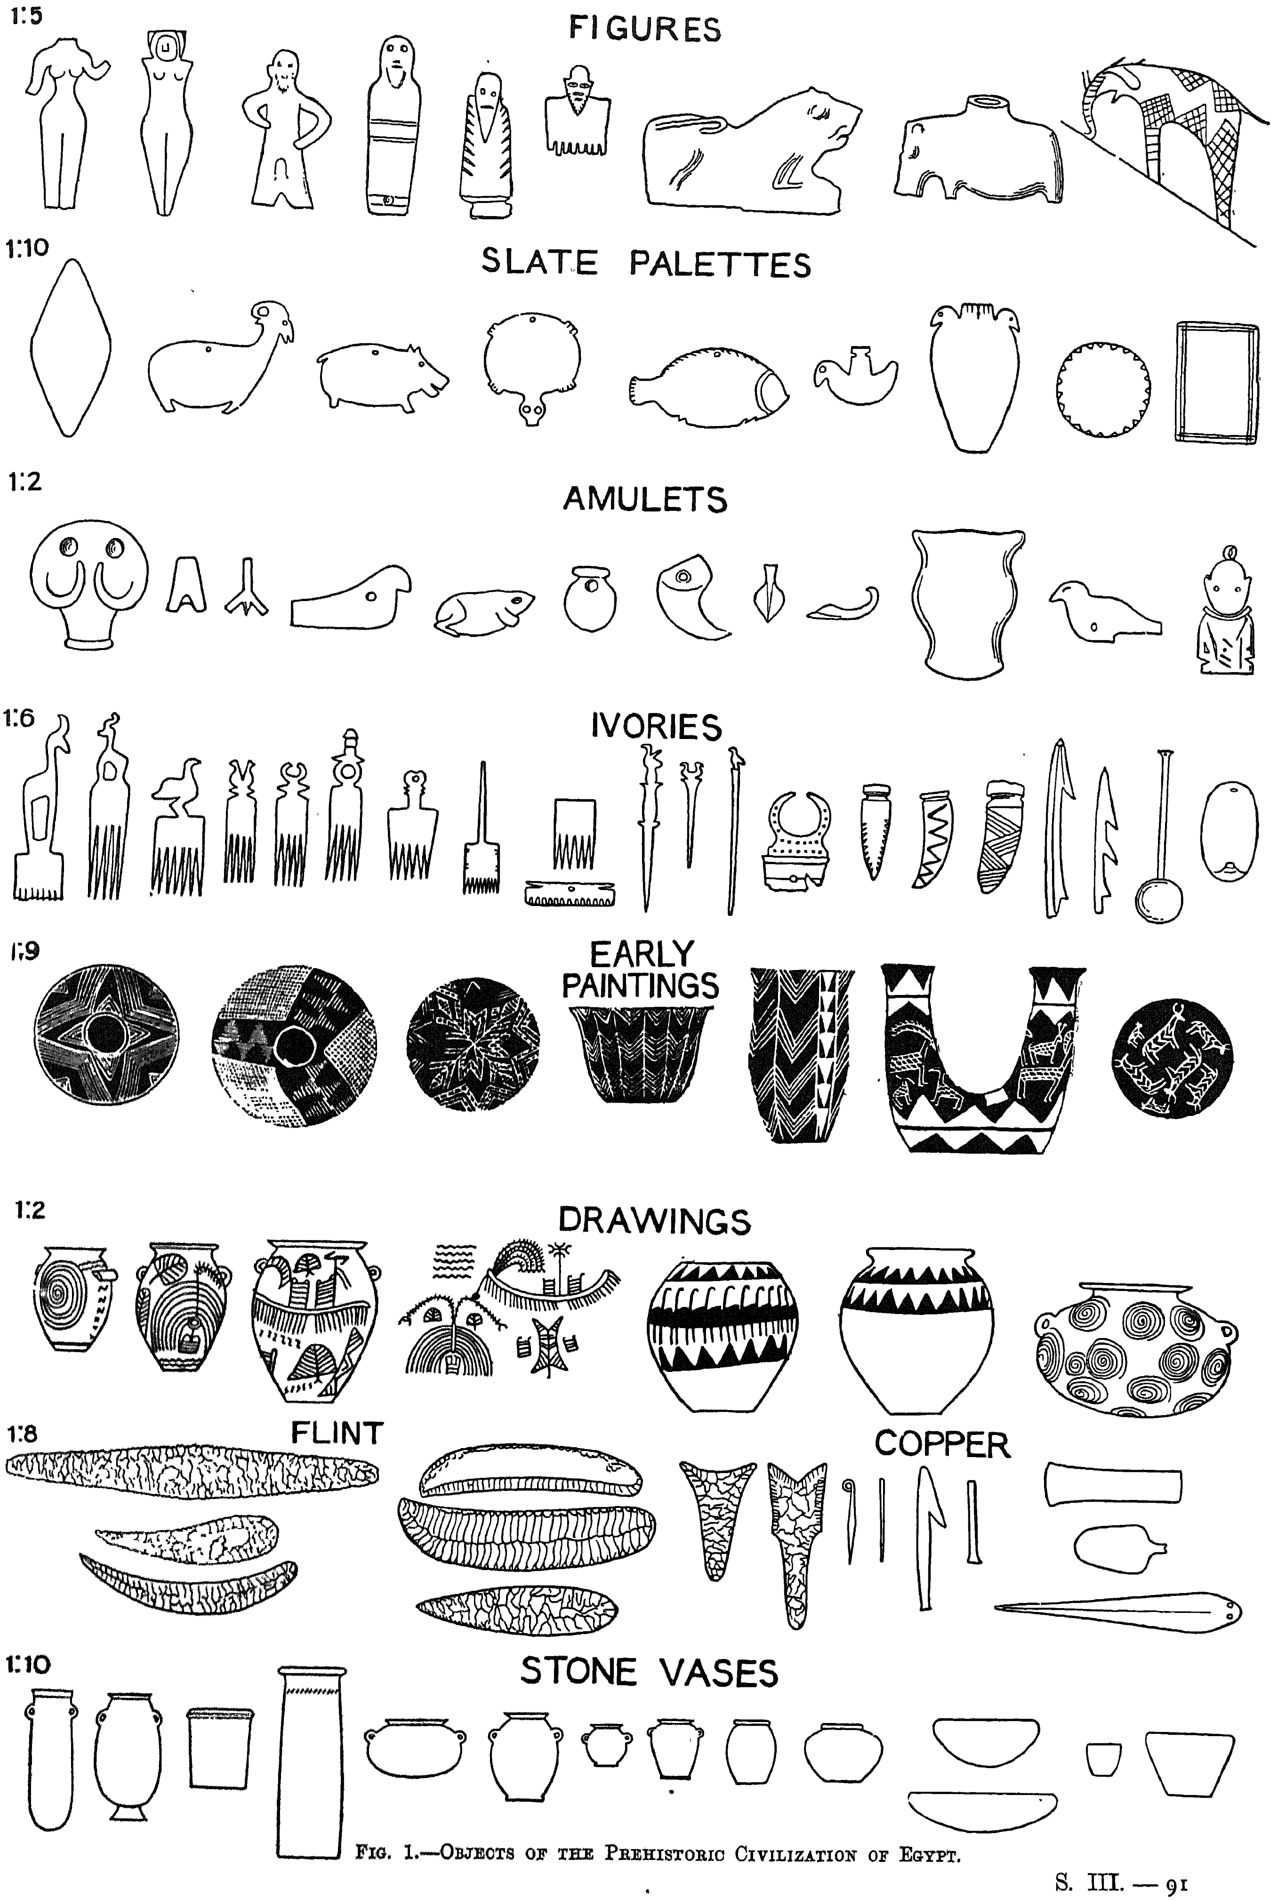


Fig. 1.—Objects of the Prehistoric Civilization of Egypt.

of the names, and the names of the *Ka* or double of each king. Our present knowledge stands thus :—

| | List Names. | | |
|---|---|---|---|
| KA name. | Tombs. | Sety I. | Manetho. |
| 1. AHA | MEN | MENA | Menes |
| 2. ZER | TA | TETA | Athothis |
| 3. ZET | ATH | ATETH | Kenkenes |
| 4. . . . | MERNEIT | ATA | Uenefes |
| 5. DEN | SETUI | HESEPTI | Usafais |
| 6. AZAB | MERPABA | MERBAPA | Miebis |
| 7. MERSEKHA | SHEMSU | SAMENPTAH | Sempses |
| 8. QAA | SEN | QEBH | Bienekhes |

On Menes, see *Recueil*, xxi. 105. King Merneit (Plate, Fig. 5) is only assigned to the name in the list of Sety I. by his presumable position; but the order and the names of the others agree with those of the list, excepting that each name has been misread somewhat in the lapse of time between those kings and Sety I., which was longer than that between Sety and ourselves.

The course of civilization was rising at the beginning of the dynasty, and the finest work appears in the middle; at the close the work is commoner and coarser.

Of the IInd Dynasty the names remaining are :—

| KA name in tombs. | Sety I. | Manetho. |
|---|---|---|
| 1. HOTEPAHAUI | BEZAU | BOETHOS |
| 2. RA NEB | KAKAU | KAIECHOS |
| 3. NETEREN | BANETEREN | BINOTHRIS |
| 4. PERABSEN | UAZNES | TLAS |
| KHASEKHEMUI | ZAZA ? | ? |

The order of the tombs is fixed, and the first three kings are named on the back of the granite figure No. 1 in Cairo Museum. The connexion of these *Ka* names with the names given by Sety I. seems probable at No. 3. Two statues and some large vases of a King Khasekhem were found at Hierakonpolis, and probably belong to this time. But so far the remains cannot be connected with the names in the historical lists.

Of the IIIrd Dynasty the step-pyramid of Saqqara is the great monument; for the late inscription at Sehel shows that Neterkhet is the name of King Zeser (1). But of the same king, Neterkhet, is also a great brick mastaba near Beit Khallaf; and by that is also a tomb of another king, Hon-nekht. The step-pyramid is the first great development of the mastaba tomb, successively added to and enlarged; and it led to the more regularly enlarged tomb of Seneferu, which was the first to have a continuous sloping casing, and so to begin the series of pyramids.

At the close of the IIIrd Dynasty we reach the period of abundant remains of the Old Kingdom, when in each reign many magnificent tombs were built by the court officials, and a complete picture of the civilization is preserved to us (1). A stone lately found at Saqqara shows the adoration of Zeser-nub (dyn. iii. 3), Teta (iii. 6), and Userkaf (v. 1); thus the kings of the IIIrd Dynasty were still worshipped in the Vth. Seneferu, whose mastaba-pyramid remains at Medum (4), was certainly the same as Sēfuris, the 8th king of the IIIrd Dynasty. His position has been cleared up by finding the name of King Shaaru (*S.B.A.P.* xxi. 108), which is clearly the origin of Sōris, the 1st king of the IVth Dynasty in the lists, thus throwing Seneferu back to the IIIrd Dynasty.

The kings of the IVth Dynasty are nearly all recorded on the numerous monuments of this age, which was above all the period of colossal building (see art. PYRAMID in ninth edition).

From the time of Seneferu the king's eldest son was high priest of Heliopolis, and in the close of the IVth Dynasty the kings took this priesthood themselves, and Shepseskaf and the Vth Dynasty kings built immense temples with obelisks dedicated to the sun-god Ra. One of these temples has been fully explored at Abusir by German work. This priesthood is echoed in later tales by the Vth Dynasty kings being said to be born of a priestess of Ra; and the title "son of Ra" begins at this date. At the close of the Vth Dynasty begins the series of inscribed pyramids, with long copies of the early form of the Book of the Dead, and the texts of a ritual nature, intended to direct and preserve the soul. These pyramids of Unas, Teta, Pepy I., Merenra, and Pepy II. were all opened in 1881. The texts are published in the *Recueil*, vols. iii.–xvi. The copper statues of Pepy I. and his

EGYPTOLOGY.

son (Plate, Fig. 6) are the most important figures remaining.

Of the VIth–Xth Dynasties no great discovery has been made The inscriptions at Siut of Khety I., Tefaba, and Khety II. belong to the age of Ka-mery-ra of the Xth Dynasty (4). The general course of art through this dark age has been traced out in the cemetery of Dendereh (15).

The group of foreign kings mainly known by scarabs (Fig. 7) and cylinders, Khyan, Samqan, Anthar, Yaqebhar, Shesha, and Uazed, are probably of the XVth – XVIth Dynasties, though some connexions place them shortly before the XIIth Dynasty. The works of Khyan have been found as far apart as Crete and Baghdad. The whole class of so-called Hyksos statues and sphinxes are also in the same position of doubt. And in this class it seems most probable that the peculiar style and physiognomy was followed in the VIIth, the XVIth, and even the XXIst Dynasty. There are certainly several different foreign types confounded together at present in one class of royal heads.

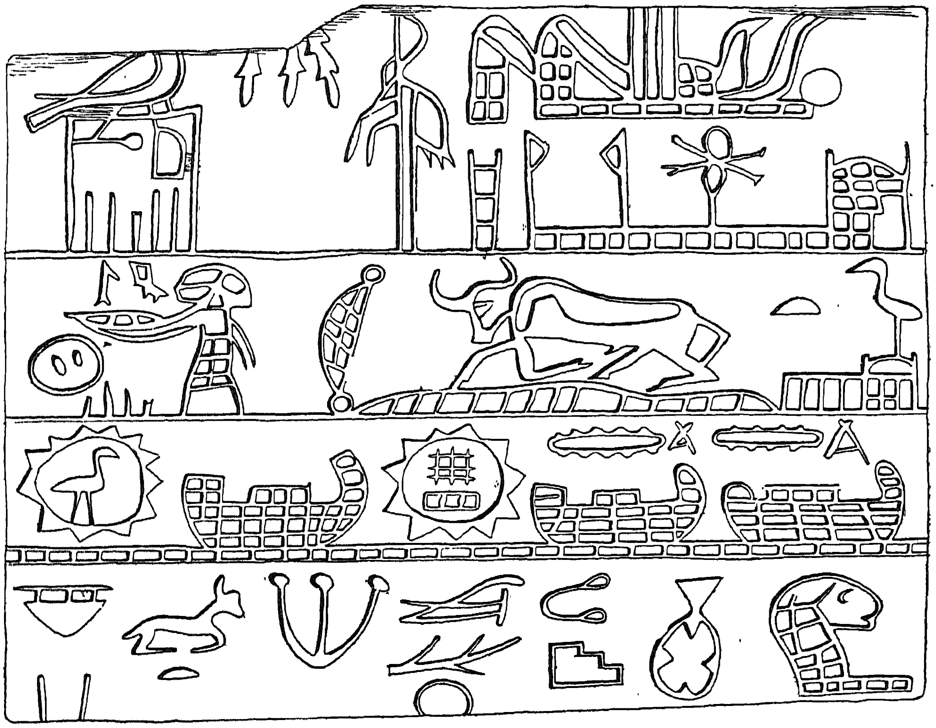

FIG. 4.—Ebony Tablet of Mena: the oldest written sentence known. (*Circa* 4700 B.C.)

The XIth Dynasty has been mainly illustrated by the sculptures of Koptos (Antef V.) (11) and of Dendereh tombs (15). The old style of the IVth to VIth Dynasties continued in a constantly degrading form until the name of Antefs shows that the beginning of the XIth Dynasty is reached (15). During that dynasty a rapid recovery took place, and the close of the XIth and early XIIth Dynasty is the highest point of this age. The main new discoveries of this period are the temple sculptures of Koptos (11) (Amenemhat I., Usertesen I.); the statues and pyramid of Lisht (Usertesen I.); the jewellery of the princesses from Dahshur (14) (Usertesen II., III. [Plate, Fig. 8], and Amenemhat III.); the pyramid of Usertesen III. (14) (Dahshur); the pyramid of Usertesen II. (18) (El Lahun); the pyramid of Hawara (17) and colossi of Biahmu (16) (Amenemhat III.).

Of the XIIIth–XVIIth Dynasties no great discovery has been made. An attempt to bring some of the Antef kings into the XIIIth Dynasty (see *A.Z.* xxxiii. 77) is contradicted both by the style of the monuments and by the list of the Turin Papyrus.

The most astonishing discovery of the 19th century was that of the actual mummies of many of the kings of the XVIIIth–XXIst Dynasties at Thebes (19). They had been collected into two hiding-places for safety, the tomb of Amenhotep II. (*a*), and the tomb of the priest-kings of the XXIst Dynasty, near Deir-el-Bahri (*b*). The bodies found (4) are those of:—

XVII Dynasty:
- 7 Seqenenra III. *b*

XVIII Dynasty:
- 1 Aahmes I. *b*
- Nefertari *b*
- 2 Amenhotep I. *b*
- 3 Tahutmes I. *b*
- 4 Tahutmes II. *b*
- 6 Tahutmes III. *b*
- 7 Amenhotep II. *a*
- 8 Tahutmes IV. *a*
- 9 Amenhotep III. *a*

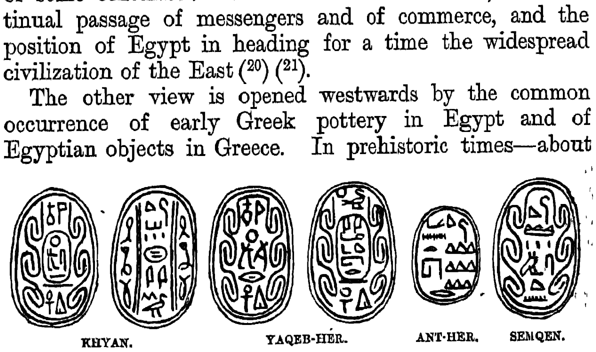
XIX Dynasty:
- 1 Ramessu I. *b*
- 2 Sety I. *b*
- 3 Ramessu II. *b*
- 4 Merenptah *a*
- 5 Sety II. *a*
- 7 Siptah *a*
- 8 Setnekht *a*

XX Dynasty:
- 1 Ramessu III. *b*
- 2 Ramessu IV. *a*
- 3 Ramessu V. *a*
- 4 Ramessu VI. *a*
- 10 Ramessu XII. (?) *b*

XXI Dynasty:
- 1 Nezemt *b*
- 2 Painezem I. *b*
- 3 Masahart *b*
- 4 Painezem II. *b*

To the age of the XVIIIth Dynasty belong some of the most important foreign connexions (2). The discovery at Tell-el-Amarna of some hundreds of tablets of cuneiform correspondence, between the kings of Egypt and the kings and governors of Mesopotamia and Syria, has shown a brief glimpse of about ten or fifteen years out of an intercourse of some centuries: we see the wealth of Asia, the continual passage of messengers and of commerce, and the position of Egypt in heading for a time the widespread civilization of the East (20) (21).

The other view is opened westwards by the common occurrence of early Greek pottery in Egypt and of Egyptian objects in Greece. In prehistoric times—about



KHYAN. YAQEB-HER. ANT-HER. SEMQEN.

FIG. 7.—Scarabs of Foreign Kings. (*Circa* 3450 B.C.)

6000 B.C.—large ships (seen painted on tombs and vases) carried the trade of the Mediterranean, and brought foreign pottery to Egypt. In the Ist Dynasty the earliest style of Greek pottery yet known is found in the tombs of the kings (about 4500 B.C.), and the silvery alloy of the royal gold points to its source in Asia Minor. In the XIIth Dynasty pottery identical with that of Crete is found in the town ruins (Kahun), and designs from objects of the XIIth Dynasty are found in Crete, as also a diorite statue from Egypt. In the XVIIIth Dynasty hundreds of pieces of vases of Rhodian types are found in the palace rubbish

of Tell-el-Amarna ([20]), and whole vases in many tombs; and in Mycenae and Cyprus many objects of Amenhotep III., and copies of designs of his age, show the common intercourse. The connexions of Egypt and Greece are the foundation for all accurate knowledge of early European chronology.

In the XIXth Dynasty the largest monument lately found is the black granite stele of Amenhotep III., reinscribed by Merenptah ([22]), giving an account of his triumph over the Libyan invaders (Plate, Fig. 9). At the close is a mention of "the people of Israel being spoiled and having no seed," an allusion the sense of which has been much disputed, but which is the only instance of the name Israel on any ancient monument. The probability of the Exodus having taken place in this reign is discussed, and the short period of Judges advocated, in a paper in *S.B.A.P.* xviii. 243.

The succession of the XXIst Dynasty kings is still obscure (see *Recueil*, xxi. 9). In the XXIInd Dynasty began a series of observations on high Nile levels at Thebes, during three centuries (see *A.Z.* xxxiv. 95, 119). These corroborate the general rising of the Nile plain by the mud of the inundation. The origin of the XXIInd Dynasty was formerly attributed to Assyria, on the ground of the names Takeloth (Tiglath), Usarkon (Sargon), and Namuroth (Nimrod); then these were disputed, and a Libyan origin advocated because the eldest sons were princes of the Mashuash (Libyan Maxyes). This fact, however, does not preclude their eastern origin; and the recent discovery of Shushanqu as a Babylonian name strongly corroborates the Mesopotamian origin of this dynasty.

Of the XXVth Dynasty are the important inscriptions at Karnak about the royal estates, the female priesthood of Amen, and the adoption of royal heiresses (see *A.Z.* xxxv. 12). For all later periods see Maspero ([3]) and Wiedemann ([5]).

The ruling family of the XXVIth Dynasty was certainly foreign, as shown by their names, and probably Libyan. The type was quite un-Egyptian, as seen in the head of Psamtik I. (*A.Z.* xxxiii. 116). The co-regency of Apries and Amasis is described on a monument, which shows that Apries was still in authority until slain in a rising in the third year of Amasis (*Recueil*, xxii. 1). The early historic Greeks in Egypt have been traced in their great settlement at Naukratis ([23]), from which a large number of very early inscriptions were obtained, and also in their fort and camp at Daphnæ ([24]). These were the two main posts of mercenaries, west and east of the Delta. The Greek and Roman periods are so well known that there is no ground for great discoveries. But the large quantities of papyri found in recent years, in the Fayum and at Oxyrhynchos ([27]), have made us familiar with the details of government and daily life, as well as providing some very valuable literary remains.

Some mention should be made of the chronology. It is generally agreed that as far back as the beginning of the XVIIIth Dynasty (1587 B.C.) there is certain dating by the occasional records of the day of the rising of Sirius in the movable calendar, which shifted through all the seasons in 1460 years ([4]). A recent discovery of a papyrus (*A.Z.*), which seems by the same method to date the XIIth Dynasty to about 2000 B.C., is, however, still debated; as such a date would leave an impossibly short time for the XIIIth–XVIIth Dynasties, it would seem rather that (if this record be accurate) the date must go back a whole cycle of 1460 years, and place the XIIth Dynasty about 3400 B.C., which would closely accord with the full chronology of Manetho as given by Africanus. There is also a vague dating of the inundation in the reign of Pepy I., which would place that VIth Dynasty about 3400 B.C. Other datings have been proposed by Mahler: (1) in connexion with the new moons for Tahutmes III., which has lately been amended by working from the visible new moon and not the theoretical; and (2) by the star diagrams in the Ramesside tombs — but as these do not accord well with the safer dating by Sirius, it seems that they were probably copied from diagrams drawn up a generation or two before. (See several papers in *A.Z.*)

In the shorter periods, within a dynasty, much help is gained by studying the family relations ([4]); even vague facts of the ages of mummies of the kings are of value in working out the family genealogies and the possibilities of lengths of reigns. In several instances the accuracy of Manetho has been well verified: the kings of the Ist Dynasty are in their right order; and in the later periods the family histories accord well with the lengths of reigns which he states; in one case, where most writers had discredited a reign of 26 years (Amenhotep II.), it has lately been entirely confirmed ([22]).

### ARCHÆOLOGY.

When the article in the ninth edition was written, scarcely anything was known of the ages of Egyptian products; even the commonest, such as pottery and beads, were entirely undated. The work of the period since 1880 has especially been the accurate dating and history of every kind of handwork. The large amount of carefully conducted and recorded excavation by English workers has given opportunity for this, and we now can date most objects to within a single dynasty, and sometimes to a single reign.

*Pottery* is the most important material for dating, as it is so common, so variable, and so short a time in use. The principal varieties are shown in Fig. 10. Of the prehistoric age there are several different kinds of pottery more or less contemporary, and there is such a great variety of form that over 900 are drawn for reference. All is hand-made. It is from this variety that the relative dating of the prehistoric periods is obtained; and the range of each form in an adopted scale of "sequence dates" is published ([8]) ([9]). The later prehistoric pottery leads us to the forms of the Ist Dynasty ([12]). Those of the IVth and Vth are well known ([13]), and the wheel became almost universal in this age. The decay of this pottery in the following dynasties has been traced ([15]), until the rise of a new style in the XIIth Dynasty (drab pottery). That class modified gradually into the XVIIIth Dynasty, when a new class of highly polished hard pottery appears ([18]). After the XIXth the periods are not accurately known till the XXVIth, when new classes appeared ([24]); the Ptolemaic is not well known, but the Roman is very familiar, especially the ribbed amphoræ beginning in the middle of the 2nd century, and the Constantine ware.

*Beads* have been carefully studied also. In the prehistoric age there is great variety, both in stone and in glazed stone and pottery. Few have been found in the Old Kingdom, but in the VIth and VIIth Dynasties discs of black and green glaze, and minute beads of carnelian and gold are usual ([9]). In the XIIth Dynasty are mostly large ball beads of amethyst, carnelian, and blue glazed pottery ([9]). In the XVIIIth Dynasty the beads are smaller; glass begins, and is very varied and common at the close. Green glazed beads and amulets are usual in the XXIIIrd Dynasty. Little is known about beads after that, until the Roman age, when a profusion of glass beads again appears. The only dated collections of beads and of pottery for study are in University College, London.

*Stone vases* are usual from the beginning of the prehistoric age ([8]) ([9]), at first cylindrical and later barrel-shaped.

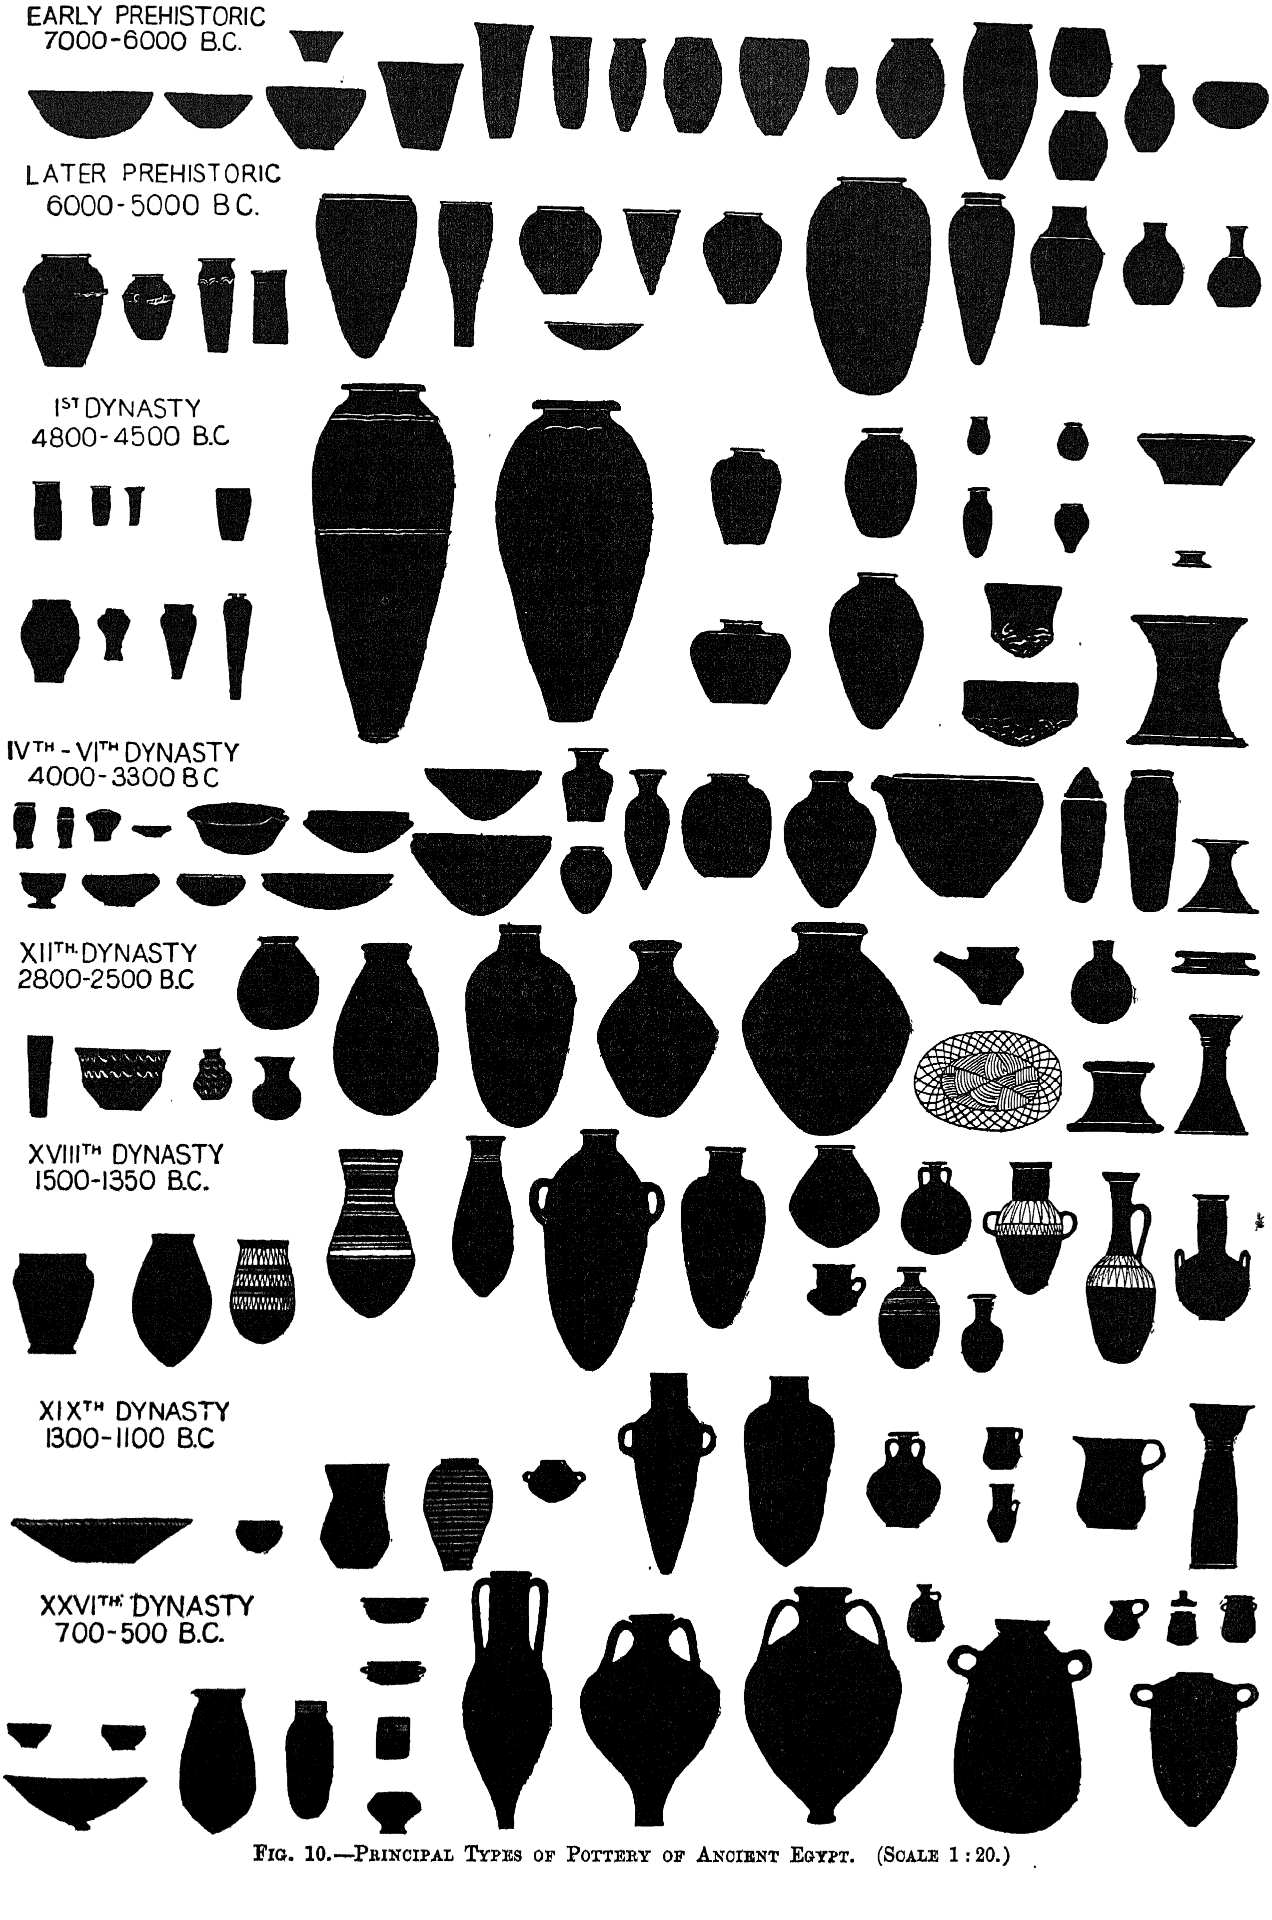


Fig. 10.—Principal Types of Pottery of Ancient Egypt. (Scale 1 : 20.)

The most magnificent stones and finest work were early in the Ist Dynasty, after which there is a continued deterioration throughout the history. Only soft stones, alabaster and serpentine, were used in the XIIth and XVIIIth Dynasties. The history of the forms has been traced from the VIth to the XVIIIth Dynasties (9). After that time stone was rarely worked into vases.

*Copper* was wrought into thin vessels as early as the Ist Dynasty. The forms of tools and weapons are well known from the XIth to the XIXth Dynasties (9) (17); and the vessels of bronze from the XVIIIth Dynasty to the Roman age; but much has yet to be done to write a continuous history. Copper alone, or with some hardening such as arsenic, was used till the XIIth Dynasty; and bronze appears general in the XVIIIth. The life-size copper statue of King Pepy I. (VIth Dynasty) is the largest piece of metal-work preserved; it shows a complete artistic mastery of the material.

*Textiles* have rarely been preserved from the prehistoric time. The finest weaving known is that of the Ist and VIth Dynasties, in royal wrappings; considerable outfits of the latter age have been found (13). Enormous quantities of mummy linen of the XVIIIth Dynasty to Roman times are found. The coloured textiles and embroideries are of Christian period, preserved owing to the change of burying immediately in the daily dress, instead of embalming (16).

## THE LANGUAGE.

The elaborate article on HIEROGLYPHICS by Dr Poole in vol. xi. of the ninth edition of the *Encyclopædia Britannica* was founded on the then (1880) standard work of De Rougé; the chief recent developments of Egyptian grammatical knowledge began, however, in that year, and they are of sufficient importance to deserve a somewhat full notice. In 1880 Ludwig Stern (*Koptische Grammatik*) admirably classified the grammatical forms of Coptic. The much more difficult task of recovering the grammar of Egyptian has occupied a quarter of a century of special study by Adolf Erman and his school at Berlin, and has now reached an advanced stage. The greater part of Egyptian texts after the Middle Kingdom having been written in what was even then practically a dead language, as dead as Latin was to the mediæval monks in Italy who wrote and spoke it, Erman selected for special investigation those texts which really represented the growth of the language at different periods, and, as he passed from one epoch to another, compared and consolidated his results.

The *Neuægyptische Grammatik* (1880) dealt with texts written in the vulgar dialect of the New Kingdom (Dyns. XVIII. to XX.). Next followed, in the *Zeitschrift für Ægyptische Sprache und Alterthumskunde*, studies on the Old Kingdom inscription of Una, and the Middle Kingdom contracts of Siut, as well as on an "Old Coptic" text of the 3rd century A.D. At this point a papyrus of stories written in the popular language of the Middle Kingdom provided Erman with a stepping-stone from Old Egyptian to the Late Egyptian of the *Neuægyptische Grammatik*, and gave the connexions that would bind solidly together the whole structure of Egyptian grammar (see *Sprache des Papyrus Westcar*, 1889). The very archaic pyramid texts enabled him to sketch the grammar of the earliest known form of Egyptian (*Zeitschrift d. Deutsch. Morgenl. Gesellschaft*, 1892), and in 1894 he was able to write a little manual of Egyptian for beginners (*Ægyptische Grammatik*), centering on the language of the standard inscriptions of the Middle and New Kingdoms, but accompanying the main sketch with references to earlier and later forms. Of the work of Erman's pupils we may mention Steindorff's little *Koptische Grammatik*, 1894, improving greatly on Stern's standard work in regard to phonology and the relationship of Coptic forms to Egyptian, and Sethe's *Das Ægyptische Verbum*, 1899. The latter is an extensive work on the verb in Egyptian and Coptic by a brilliant and laborious philologist. Owing to the very imperfect notation of sound in the writing, the highly important subject of the verbal roots and verbal forms was perhaps the obscurest branch of Egyptian grammar when Sethe first attacked it in 1895. The subject has been reviewed by Erman, *Die Flexion des Ægyptischen Verbums* in the *Sitzungsberichte* of the Berlin Academy, 1900. The Berlin school, having settled the main lines of the grammar, next turned its attention to lexicography. It has devised a scheme, founded on that for the Latin Thesaurus of the Berlin Academy, which almost mechanically sorts the whole number of occurrences of every word in any text examined. Scholars in England, America, and Denmark, as well as in Germany, are taking part in this great enterprise, and though the completion of it may be far off, the collections of classified material already made are very valuable for consultation. At present Egyptologists depend on Heinrich Brugsch's admirable but somewhat antiquated *Wörterbuch* and on Levi's useful but entirely uncritical *Vocabolario*. Though demotic has not yet received serious attention at Berlin, the influence of that great school has made itself felt amongst demotists, especially in Switzerland, Germany, America, and England. The death of Heinrich Brugsch in 1895 was a very severe blow to demotic studies; but it must be admitted that his brilliant gifts lay in other directions than exact grammatical analysis. Apart from their philological interest, as giving the history of a remarkable language during a period of several thousand years, the grammatical studies of the last quarter of the 19th century are beginning to bear fruit in regard to the exact interpretation of historical documents on Egyptian monuments and papyri. Not long ago the supposed meaning of these was extracted chiefly by brilliant guessing, and the published translations of even the best scholars could carry no guarantee of more than approximate exactitude, where the sense depended at all on correct recognition of the syntax. Now the translator proceeds in Egyptian with some of the sureness with which he would deal with Latin or Greek. The meaning of many words may be still unknown, and many constructions are still obscure; but at least he can distinguish fairly between a correct text and a corrupt text. Egyptian writing lent itself only too easily to misunderstanding, and the writings of one period were but half intelligible to the learned scribes of another. The mistaken readings of the old inscriptions by the priests at Abydos, when attempting to record the names of the kings of the Ist Dynasty on the walls of the temple of Sety I., are now admitted on all sides; and no palæographer, whether his field be Greek, Latin, Arabic, Persian, or any other class of MSS., will be surprised to hear that the Egyptian papyri and inscriptions abound in corruptions and mistakes. The translator of to-day can, if he wishes, mark where certainty ends and mere conjecture begins, and it is to be hoped that advantage will be taken more widely of this new power. The Egyptologist who has long lived in the realm of conjecture is too prone to consider any series of guesses good enough to serve as a translation, and forgets to insert the notes of interrogation which would warn workers in other fields from implicit trust.

The stages of the language are now distinguished as follows :—

*Old Egyptian.*—This is properly the language of the Old Kingdom. In it we have (*a*) the recently discovered inscriptions of the Ist Dynasty, too brief and concise to throw much light on the language of that time; and the great collections of spells and ritual texts found inscribed in the Pyramids of the Vth and VIth Dynasties, which must even then have been of high antiquity, though they contain later additions made in the same style. (*b*) A few historical texts and an abundance of short inscriptions representing the language of the IVth, Vth, and VIth Dynasties.

The ordinary *literary language* of the monuments of its later ages is modelled on Old Egyptian. It is often much affected by contemporary speech, but preserves in the main the characteristics of the language of the Old Kingdom.

*Middle and Late Egyptian.*—These represent the vulgar speech of the Middle and New Kingdom respectively. The former is found chiefly in tales, letters, &c., written in hieratic on papyri of the XIIIth Dynasty to the end of the Middle Kingdom; also in some inscriptions of the XVIIIth Dynasty. Late Egyptian is seen in hieratic papyri of the XVIIIth to the XXIst Dynasties. The spelling of Late Egyptian is very extraordinary, full of false etymologies, otiose signs, &c., the old orthography being quite unable to adapt itself neatly to the profoundly modified language; nevertheless, this clumsy spelling is expressive, and the very mistakes are instructive as to the pronunciation.

*Demotic.*—Demotic Egyptian seems to represent approximately the vulgar speech of the Saite period, and is written in the "demotic" character, which may be traced back to the XXVth Dynasty, if not to a still earlier time. With but moderate changes, this form of the language is found in documents reaching down to the fall of paganism in the 4th century A.D.[1] In the earlier times the spelling is excessively concise; in later Ptolemaic and in the Roman period, it is comparatively full and expressive. Though documents from Egypt in Greek are more abundant than in demotic, the language of the ruling classes had not penetrated the masses deeply.

*Coptic.*—This, in the main, represents the popular language of early Christian Egypt from the 3rd to perhaps the 8th century A.D., when the growth of Coptic as a literary language must have ceased. The Greek alphabet, reinforced by a few signs borrowed from demotic, rendered the spoken tongue so accurately that five distinct, though closely allied, dialects are readily distinguishable in Coptic MSS.; ample remains are found of renderings of the Scriptures into all these dialects. The distinctions between the dialects consist largely in pronunciation, but extend also to the vocabulary, word-formation, and syntax. Such interchanges are found as *l* for *r*, ϭ (*k*, *ch*) for ϫ (*dj*), final *i* for final *e*, *a* for *e*, *a* for *o*. Early in the 2nd century A.D., pagan Egyptians, or perhaps foreigners settled in Egypt, essayed, as yet unskilfully, to write the native language in Greek letters. This *Old Coptic*, as it is termed, was still almost entirely free from Greek loan-words, and its strong archaisms are doubtless accounted for by the literary language having moved more slowly than the speech of the people. Christian Coptic, though probably at first contemporary with some documents of Old Coptic, contrasts strongly with the latter. The monks whose task it was to perfect the adaptation of the alphabet to the dialects of Egypt and translate the Scriptures out of the Greek, flung away all pagan traditions. It is clear that the basis which they chose for the new literature was the simplest language of daily life in the monasteries, charged as it was with expressions taken from Greek, pre-eminently the language of patristic Christianity. There is evidence that the amount of stress on syllables, and the consequent length of vowels, varied greatly in spoken Coptic, and that the variation gave much trouble to the scribes; the early Christian writers must have taken as a model for each dialect the deliberate speech of grave elders or preachers, and so secured a uniform system of accentuation. The remains of Old Coptic, though very instructive in their marked peculiarities, are as yet too few for definite classification. The main divisions of Christian Coptic as recognized and named at present are: Sahidic (formerly called Theban); spoken in the upper Thebais. Akhmimic; in the neighbourhood of Akhmim. Fayumic; in the Fayum (formerly named wrongly "Bashmuric," from a province of the Delta). Memphite; in the neighbourhood of Memphis. Bohairic, the dialect of the "coast district" (formerly named "Memphite"); spoken in the north-western Delta. Coptic, much alloyed with Arabic, was spoken in Upper Egypt as late as the 15th century, but it has long been a dead language.[2] Sahidic and Bohairic are the most important dialects, each of these having left abundant remains; the former spread over the whole of Upper Egypt, and the latter since the 15th century has been the language of the sacred books of Christianity throughout the country, owing to the hierarchical importance of Alexandria and the influence of the ancient monasteries established in the north-western desert.

Coptic is the only stage of the language in which the spelling gives a clear idea of the pronunciation. It is therefore the mainstay of the scholar in investigating or restoring the word-forms of the ancient language. Greek transcriptions of Egyptian names are sometimes valuable as evidence for the vocalization of Egyptian, and they abound as far back as the 4th century B.C., but they seem very inaccurate. A few cuneiform transcriptions, reaching as far back as the XVIIIth Dynasty, also give valuable hints. Coptic itself is of course quite inadequate to enable us to restore Old Egyptian. In it the Old Egyptian verbal forms are mostly replaced by periphrases; though the strong roots are often preserved entire, the weaker consonants and the ע have largely or entirely disappeared, so that the language appears as one of biliteral rather than triliteral roots. Coptic is strongly impregnated with Greek words adopted late; moreover, a certain number of Semitic loan-words had flowed into Egyptian from the 16th century B.C. onwards, displacing earlier words. It is only by the most careful scrutiny and the exercise of the most piercing insight that the imperfectly spelled Egyptian is made to yield up one grammatical secret after another in the light brought to bear upon it from Coptic. Demotic grammar ought soon to be thoroughly comprehensible in its forms, and the study of Late Egyptian should not stand far behind that of demotic. Middle Egyptian and Old Egyptian, on the other hand, will perhaps always be to us little more than consonantal skeletons, the flesh and blood of their vocalization being for the most part irretrievably lost.

In common with the Semitic languages, the Berber languages of North Africa, and the Cushite languages of North-East Africa, Egyptian of all periods possesses grammatical gender, expressing masculine and feminine. Singularly few language groups have this peculiarity; and our own great Indo-European group, which possesses it, is distinguished from those above mentioned by having the neuter gender in addition. The characteristic triliteral roots of all the Semitic languages seemed to separate them widely from others; but certain traits have caused the Egyptian, Berber, and Cushite groups to be classed together as three subfamilies of a Hamitic group, remotely related to the Semitic. The biliteral character of Coptic, and the biliteralism which was believed to exist in Egyptian, led philologists to suspect that Egyptian might be a surviving witness to that far-off stage of the Semitic languages when triliteral roots had not yet been formed from presumed original biliterals; Sethe's investigations, however, prove that the Coptic biliterals are themselves derived from Old Egyptian triliterals, and that

[1] In the temple of Philæ, where the worship of Isis was permitted to continue till the reign of Justinian, Brugsch found demotic inscriptions with dates to the end of the 5th century.

[2] The Arabic dialects which gradually displaced Coptic as Mahommedanism supplanted Christanity adopted but a few words of the old native stock.

the triliteral roots enormously preponderated in Egyptian of the earliest known form; that view is, therefore, no longer tenable. Many remarkable resemblances have been observed in the grammatical structure of the Berber and Cushite groups with Semitic (cf. Zimmern, *Vergleichende Grammatik d. Semitischen Sprache*, especially pronouns and verbs); but the relationship must be very distant, and there are no ancient documents that can take back the history of any one of those languages more than a few centuries. Their connexion with Semitic and Egyptian, therefore, remains at present an obscure though probable hypothesis. On the other hand, Egyptian is certainly related to Semitic. Even before the triliterality of Old Egyptian was recognized, Erman showed that the so-called pseudo-participle had been really in meaning and in form a precise analogue of the Semitic perfect, though its original employment was almost obsolete in the time of the earliest known texts. Triliteralism is considered the most essential and most peculiar feature of Semitic. But there are, besides, many other resemblances in structure between the Semitic languages and Egyptian, so that, although the two vocabularies present few points of clear contact, there seems no adequate reason for doubting that Egyptian was originally a characteristic member of the Semitic family of languages. See Erman, *Das Verhältniss d. Ægyptischen zu d. Semitischen Sprachen* (*Zeitschrift d. Deutschen Morgenl. Gesellschaft*, 1892); Zimmern, *Vergl. Gram.* 1898; Erman, *Flexion d. Ægyptischen Verbum* (*Sitzungsberichte d. Berl. Akad.*, 1900). The Egyptians proper are not, and so far as we can tell never were, Semitic in physical feature. As a possible explanation of the facts, Erman supposes that a horde of conquering Semites, like the Arabs of a later day, imposed their language on the country, but disappeared, being weakened by the climate or absorbed by the native population. The latter acquired the Semitic language imperfectly from their conquerors; they expressed the verbal conjugations by periphrases, mispronounced the consonants, and so changed greatly the appearance of the vocabulary, which also would certainly contain a large proportion of native non-Semitic roots. Strong consonants gave way to weak consonants (as ق (*q*) to ا ('), in the modern Arabic of Egypt), and then the weak consonants disappearing altogether produced biliterals from the triliterals. Much of this must have taken place, according to the theory, in the prehistoric period; but the loss of weak consonants, of *y*, and of one of two repeated consonants, and the development of periphrastic conjugations continued to the end. The typical Coptic root thus became biliteral rather than triliteral, and the verb, by means of periphrases, developed tenses of remarkable precision—perhaps under the influence of Greek. Such verbal resemblances as exist between Coptic and Semitic are largely due to late exchanges with Semitic neighbours.

The following sketch of the Egyptian language, mainly in its earliest form, which dates from some three or four thousand years B.C., is founded upon Erman's works. It will serve to contrast with Coptic grammar on the one hand and Semitic grammar on the other.

*The Egyptian Alphabet.*

=*y*; so transcribed in this article, but is often א, especially at the beginning of words, and from the earliest times is used in a manner corresponding to the Arabic *hamza*, to indicate a prosthetic vowel. Often lost or changed to '.

=' (א); easily lost or changes to *y*.

=' (ע); lost in Coptic. This rare sound, well known in Semitic, occurs also in Berber and Cushite languages.

=*w*; often changes to *y*.

=*b*.

=*p*.

=*f*.

=*m*.

=*n*.

=*r*; often lost, or changes to *y*. *r* and *l* are distinguished in later demotic and in Coptic.

=*h*.
=*ḥ*. } distinction lost in Coptic.

=*ḫ*; in Coptic ϣ (*sh*) or ϧ (*kh*) correspond to it.

=*ẖ*; generally written with (*š*) in the Old Kingdom, but corresponds to *kh* in Coptic.

=*s*.
=*ś*. } distinction lost at the end of the Old Kingdom.

=*š* (*sh*).

=*q*; Coptic ⲕ.

=*k*
=*g* } Coptic ⲕ; or ϫ, ϭ according to dialect.

=*t*; often lost at the end of words.

=*ṯ* (*θ*); often changes to *t*. Coptic ⲧ; or ϫ, ϭ.

=*d*; in Coptic reduced to *t*.

=*ḏ* (*z*); often changes to *d*; in Coptic ϫ.

*Roots.*

Egyptian roots consist of consonants and semi-consonants only, the inflexion being effected by internal vowel-change and the addition of consonants or vowels at the beginning or end. The Egyptian system of writing, as opposed to the Coptic, showed only the consonantal skeletons of words: it could not record internal vowel-changes; and semi-consonants, even when radicals, were often omitted in writing.

*Personal Pronouns.*

| | | | | |
|---|---|---|---|---|
| Sing. | 1. c. *yw* (?) later *wy*. | Pl. | 1. c. *n*. | Du. |
| | 2. m. *kw*. | | 2. c. *ṯn*. | 2. c. *ṯny*. |
| | f. *ṯn*. | | | |
| | 3. m. **fy*, surviving only in a special verbal form. | | 3. m. *śn*, early lost, except as suffix. | 3. c. *śny*. |
| | f. *śy*. | | f. **śt*, surviving as 3. c. | |

From these are derived the suffixes, which are shortened forms attached to nouns to express the possessor, and to verbs to express the subject. In the latter case the verb was probably in the participle, so that *śḏmyy-śn*, "they hear," is literally "hearing are they." The singular suffixes are: 1. c. -*y*; 2. m. -*k*, f. -*ṯ*; 3. m. -*f*, f. -*ś*;—the dual and plural have no special forms.

Another series of absolute pronouns is: 2. m. *ṯwt*, *ṯw*; f. *ṯmt*, *ṯm*; 3. m. *śwt*, *św*; f. *śtt*, *śt*. Of these *ṯwt*, *ṯmt*, &c., are emphatic forms.

Many of the above absolute pronouns were almost obsolete even in the Old Kingdom. In ordinary texts some survive, especially as objects of verbs, namely: *wy*, *tw*, *tn*, *sw*, *st*. The suffixes of all numbers and persons except the dual were in full use throughout, to Coptic; -*śn*, however, giving way to a new suffix, -*w*, which developed first in the New Kingdom.

Another absolute pronoun of the first person is *ynk*, ⲁⲛⲟⲕ, like Heb. אנכי. It is associated with a series for the second and third persons: *nt-k*, *nt-ṯ*, *nt-f*, *nt-śn*, &c.; but from their history, use, and form, it seems probable that the last are of later formation, and are not to be connected with the Semitic pronouns (chiefly of the 2nd person) resembling them.

*Demonstrative Pronouns.*

There are several series based on m. *p*; f. *t*; pl. *n*; but *n* as a plural seems later than the other two. From them are developed a weak demonstrative to which possessive suffixes can be attached, producing the definite and possessive articles (*p'*, *t'*, *n'*, "the," *p'y-f*, "his," *p'y-s* "her," &c.) of Middle Egyptian and the later language.

*Nouns.*

Two genders, m. (ending *w*, or nothing), f. (ending *ṯ*). Three numbers: singular, dual (m. *wy*, f. *ty*, gradually became obsolete), plural (m. *w*; f. *wt*). No case-endings are recognizable, but construct forms—to judge by Coptic—were in use. Masculine and feminine nouns of instrument or material are formed from verbal roots by prefixing *m*; *e.g.*, *m.sdm.t*, "stibium," from *sdm*, "paint the eye." Substantives and adjectives are formed from substantives and prepositions by the addition of *y* in the masculine; *e.g.*, *n.t*, "city," *nt.y*, "belonging to a city," "citizen"; *ḥr*, "upon," *ḥr.y* (f. *ḥr.t*; pl. *ḥr.w*), "upper." This is not unlike the Semitic *nisbe* ending *iy*, *ay* (*e.g.*, Ar. *beled*, "city," *beledi*, "belonging to a city"). Adjectives follow the nouns they qualify.

*Numerals.*

1, *w'*; 2, *śn*; 3, *ḫmt*; 4, *fdw*; 5, *dw'*; 6, *sys*; 7, *sfḫ*; 8, *ḫmn*; 9, *psḏ*; 10, *mt*. 2, 6, 7, 8, and 9 (?) resemble Semitic numerals. 20 and 30 (*m'b*) had special names; 40–90 were named as if plurals of the units 4–9, as in Semitic. 100, *šnt*; 1000, *ḫ'*; 10,000, *ḏb'*; 100,000, *ḫfnw*.

*Verbs.*

The forms observable in hieroglyphic writing lead to the following classification:—

| | | |
|---|---|---|
| STRONG VERBS. | Biliteral . . | Often showing traces of an original III. inf.; in early times very rare. |
| | Triliteral . . | Very numerous. |
| | Quadriliteral, Quinqueliteral | Generally formed by reduplication. In late Egyptian they were no longer inflected, and were conjugated with the help of *yry*, "do." |
| WEAK VERBS. | II. geminatæ . | Properly triliterals, but, with the 2nd or 3rd radical alike, these coalesced in many forms where no vowel intervened, and gave the word the appearance of a biliteral. |
| | III. gem. . . . | Rare. |
| | III. inf. . . . | Numerous. III. *w*, and III. *y* were unified early. Some very common verbs, "do," "give," "come," "bring" are irregular. |
| | IV. inf. . . . | Partly derived from adjectival formations in *y*, from nouns and infinitives:—*e.g.*, *ś.yp*, inf. *śypt*; adj. *śypty*; verb (4 lit.), *śypty*. |

Many verbs with weak consonants—1*y*, 1*w*, II. inf. (*m*[*w*]*t*), and those with א—are particularly difficult to trace accurately, owing to defective writing.

It seems that all the above classes may be divided into two main groups, according to the form of the infinitive:—with masculine infinitive the strong triliteral type, and with feminine infinitive the type of the III. inf. The former group includes all except III. inf., IV. inf., and the causative of the biliterals, which belong to the second group.

It is probable that the verb had a special form denoting condition, as in Arabic. There was a causative form prefixing *ś*, and traces of forms resembling *Piël* and *Niphal* are observed. Some roots are reduplicated wholly or in part with a frequentative meaning, and there are traces of gemination of radicals.

*Pseudo-Participle.*—In very early texts this is the past indicative, but more commonly it is used in sentences such as, *gm-n-f wy 'ḥ'.kwy*, "he found me I stood," *i.e.*, "he found me standing." The indicative use was soon given up and the pseudo-participle was employed only as predicate, especially indicating a state; *e.g.*, *ntr.t šm.ty*, "the goddess goes"; *yw-k wḏ'.ty*, "thou art prosperous." The endings were almost entirely lost in New Egyptian. For early times they stand thus:—

| | | | | | | |
|---|---|---|---|---|---|---|
| Sing. | 3. | masc. | *y*, late *w*. | Dual *wyy*. | Pl. | *w*. |
| | | fem. | *ty*. | *tyyw*. | | *ty*. |
| | 2. | masc. | *ty*. | | | *tywny*. |
| | | fem. | *ty*. | | | |
| | 1. | c. | *kwy*. | | | *wyn*. |

The pseudo-participle seems, by its inflection, to have been the perfect of the original Semitic conjugation. The simplest form being that of the 3rd person, it is best arranged like the corresponding tense in Semitic grammars, beginning with that person. There is no trace of the Semitic imperfect in Egyptian. The ordinary conjugation is formed quite differently. The verbal stem is here followed by the subject-suffix or substantive—*śḏm-f*, "he hears"; "*śḏmw štn*, "the king hears." It is varied by the addition of particles, &c., *n*, *yn*, *ḫr*, *tw*, thus:—

*śḏm-f*, "he hears"; *śḏm-w-f*, "he is heard" (pl. *śḏm-yy-śn*, "they are heard"); *śḏm-tw-f*, "he is heard"; *śḏm-n-f*, "he heard"; *śḏm-n-tw-f*, "he was heard"; also, *śḏm-yn-f*, *śḏm-ḫr-f*, *śḏm-k'-f*. Each form has special uses, generally difficult to define. *śḏm-f* seems rather to be imperfect, *śḏm-n-f* perfect, and generally to express the past. Later, *śḏm-f* is ordinarily expressed by periphrases; but by the loss of *n*, *śḏm-n-f* became itself *sdm-f*, which is the ordinary past in demotic. Coptic preserves *śḏm-f* forms of many verbs in its causative (*e.g.*, ⲦⲀⲚϦⲞϤ "cause him to live," from Egyptian *dy.t 'nḫ-f*), and, in its periphrastic conjugation, the same forms of *wn*, "be," and *yry*, "do." With *śḏm-f* (*śeḏmo-f*) was a more emphatic form (*eśḏomef*), at any rate in the weak verbs.

The above, with the relative forms mentioned below, are supposed by Erman to be derived from the participle, which is placed first for emphasis: thus, *śḏm.w štn*, "hearing is the king"; *śḏm-f*, for *sḏm-fy*, "hearing he is." This Egyptian paraphrase of Semitic is just like the Irish paraphrase of English, "It is hearing he is."

The *imperative* shows no ending in the singular; in the plural it has *y*, and later *w*; cf. Semitic imperative.

The *infinitive* is of special importance on account of its being preserved very fully in Coptic. It is generally of masculine form, but feminine in III. inf. (as in Semitic), and in causatives of biliterals.

There are relative forms of *śḏm-f* and *śḏm-n-f*, respectively *śḏm.w-f* (masc.), *śḏm.t-n-f* (fem.), &c. They are used when the relative is the object of the relative sentence, or has any other position than the subject. Thus *śḏm.t-f* may mean "she whom he hears," "she who[se praises] he hears," "she [to] whom he hears [someone speaking]," &c. There are close analogies between the function of the relative particles in Egyptian and Semitic; and the Berber languages possess a relative form of the verb.

*Participles.*—These are active and passive, perfect and imperfect, in the old language, but all are replaced by periphrases in Coptic.

*Verbal Adjectives.*—There is a peculiar formation, *śḏm-ty-fy*, "he who shall hear," probably meaning originally "he is a hearer," *śḏm.ty* being an adjective in *y* formed from a feminine (*t*) form of the infinitive, which is occasionally found even in triliteral verbs; the endings are: sing., masc. *ty-fy*, fem. *ty-śy*; pl., masc. *ty-śn*, fem. *ty-śt*. It is found only in Old Egyptian.

*Particles.*—There seems to be no special formation for adverbs, and little use is made of adverbial expressions. Prepositions, simple and compound, are numerous. Some of the commonest simple propositions are *n* "for," *r* "to," *m* "in, from," *ḥr* "upon." A few enclitic conjunctions exist, but they are indefinite in meaning—*śwt* a vague "but," *grt* a vague "moreover," &c.

Coptic presents a remarkable contrast to Egyptian in the precision of its periphrastic conjugation. There are two present tenses, an imperfect, two perfects, a pluperfect, a present and a past frequentative, and three futures besides future perfect; there are also conjunctive and optative forms. The negatives of some of these are expressed by special prefixes. The gradual growth of these new forms can be traced through all the stages of Egyptian. Throughout the history of the language we note a tendency to periphrasis and pleonasm; but there was no great advance towards *precision* before demotic. In demotic there are distinguishable a present tense, imperfect, perfect, frequentative, future, future perfect, conjunctive, and optative; also present, past, and future negatives, &c. The passive was extinct before demotic; demotic and Coptic express it, clumsily it must be confessed, by an impersonal "they," *e.g.*, "they bore him" stands for "he was born."

It is worth noting how, in other departments besides the verb, the Egyptian language was far better adapted to practical ends during and after the period of the Deltaic dynasties (XXII.–XXX.) than ever it was before. It was both simplified and enriched. The inflections rapidly disappeared, and little was left of the distinctions between masculine and feminine, singular dual and plural—except in the pronouns. The dual number had been given up entirely at an earlier date. The pronouns, both personal and demonstrative, retained their forms very fully. As prefixes, suffixes, and articles, they, together with some auxiliary verbs, provided the principal mechanism of the renovated language. An abundant supply of useful adverbs was gradually accumulated, as well as conjunctions, so far as the functions of the latter were not already performed by the verbal prefixes. These great improvements in the language correspond to great changes in the economic condition of the country; they were the result of active trade and constant intercourse of all classes of Egyptians with foreigners from Europe and Asia. Probably the best stage of Egyptian speech was that which immediately preceded Coptic. Though Coptic is here and there more exactly expressive than the best demotic, it was spoilt

by too much Greek, duplicating and too often expelling native expressions that were already adequate for its very simple requirements. Above all, it is absurdly and clumsily pleonastic.

### The Writing.

The ancient Egyptian system of writing, so far as we know, originated, developed, and finally expired strictly within the limits of the Nile Valley. The germ of its existence may have come from without, but, as we know it, it is essentially Egyptian and intended for the expression of the Egyptian language. About the 2nd century B.C. the semi-barbarous inhabitants of Ethiopia contrived to adapt it to their own idiom in modified forms of hieroglyphic and demotic, which are still undecipherable, and the demotic writing of Ethiopia may have been employed as late as the 5th or 6th century A.D. Egyptian hieroglyphic was carried by conquest into Syria, certainly under the XIXth Dynasty, and again under the XXVIth for the engraving of Egyptian inscriptions; but in the earlier period the cuneiform syllabary, and in the later the "Phœnician" alphabet, had obtained a firm hold there, and we may be sure that no attempt was made to substitute the Egyptian system for either of these. In very early times a number of systems of writing already reigned in different countries forming a compact and not very large area—from South Arabia to Asia Minor, and from Persia to Crete and Egypt. Whether they all sprang from one common stock of picture-writing we shall perhaps never know, nor can we as yet trace the influence which one great system may have had on another. From the evidence at present available, it seems likely that Egyptian hieroglyphic was not the direct ancestor of any system outside the valley of the Nile.

It is certain that the mode of writing in Egypt from the IVth Dynasty onwards was essentially the same as that which was extinguished by the fall of paganism in the 4th century A.D. Its elements in the hieroglyphic form are pictorial, but each hieroglyph has one or more well-defined functions, fixed by convention in such a manner that the Egyptian language is expressed word by word. Although a picture sign may at times have embarrassed the skilled native reader by offering a choice of fixed values or functions, it was never intended to convey merely an idea, so as to leave to him the task of putting the idea into his own words. How far this holds good for the period before the IVth Dynasty it is difficult to say. The known inscriptions of the earlier times are so brief and so limited in range that the mode of writing them cannot yet be fully investigated. As far back as the Ist Dynasty, phonograms (see below) were in full use. But the spelling then was very concise: it is possible that some of the slighter words, such as prepositions, were omitted in the writing and were intended to be supplied from the context. As a whole, we gain the impression that a really distinct and more primitive stage of hieroglyphic writing by a substantially vaguer notation of words lay not far behind the time of the Ist Dynasty.

The employments of the signs are of three kinds: each represents (1) a whole word; or (2) a sound as part of a word; or (3) pictorially defines the meaning of a word the sound of which has already been given by a sign or group of signs preceding. For instance, is the conventional picture of a draughtboard (shown in plan), with the draughtsmen (shown in elevation) on its edge:—this sign (1) signifies the word *mn*, "set," "firm"; or (2), in the group , represents the same sound as part of the word *mnḫ*, "good"; or (3), in the group , *snt*, it shows that the meaning is a "draughtboard," or "draughts." Thus signs, according to their employment, are said to be (1) "word-signs," (2) "phonograms," or (3) "determinatives."

Word-Signs.—The word-sign value of a sign is, in the first place, the name of the object it represents, or of some material, or quality, or action, or idea suggested by it. Thus is *ḥr*, "face"; , a vase of ointment, is *mrḥ.t*, "ointment"; is *wdb*, "turn." Much investigation is still required to establish the origins of the values of the signs; in some cases the connexion between the pictures and the primary values seems to be curiously remote. Probably all the signs in the hieroglyphic signary can be employed in their primary sense. The *secondary* value expresses the consonantal root of the name, and any, or almost any, derivative from that root: as when , a mat with a cake upon it, is not only *ḥtp*, an "offering-mat," but also *ḥtp* in the sense of "conciliation," "peace," "rest," "setting" (of the sun), with many derivatives. In the third place, some signs may be *transferred* to express another root having the same consonants as the first: thus , the ear, by a play upon words can express not only *śḏm*, "hear," but also *śdm*, "paint the eyes."

Phonograms.—Only a limited number of signs are found with this use, but they are of the greatest importance. By searching throughout the whole mass of inscriptions, earlier than the periods of Greek and Roman rule, when great liberties were taken with the writing, probably no more than one hundred different phonograms can be found. The number of those commonly employed in good writing is between seventy and eighty. The most important phonograms are the uniliteral or alphabetic signs, twenty-four in number in the Old Kingdom and without any homophones: later these were increased by homophones to thirty. Of biliteral phonograms—each expressing a combination of two consonants—there were about fifty commonly used: some fifteen or twenty were rarely used. As Egyptian roots seldom exceeded three letters, there was no need for triliteral phonograms to spell them. There is, however, one triliteral phonogram, the eagle, , *tyw*, or *tiu* (?), used for the plural ending of adjectives in *y* formed from words ending in *t* (whether radical or the feminine ending).

The phonetic values of the signs are derived from their word-sign values and consist usually of the bare root, though there are rare examples of the retention of a flexional ending; they often ignore also the weaker consonants of the root, and on the same principle reduce a repeated consonant to a single one, as when the hoe , *ḥnn*, has the phonetic value *ḥn*. The history of some of the alphabetic signs is still very obscure, but a sufficient number of them have been explained to make it nearly certain that the values of all were obtained on the same principles.[1] Some of the ancient words from which the phonetic values were derived probably fell very early into disuse, and may never be discoverable in the texts that have come down to us. The following are among those most easily explained:—

, reed flower, value *y* and ℵ; from , *y'*, "reed."

(It seems as if the two values *y* and ℵ are obtained by choosing first one and then the other of the two semi-consonants composing the name.)

, forearm, value ʿ(ν); from , ʿ(ν), "hand."

, mouth, = *r*; ,, , *r*, "mouth."

, belly and teats, = *ẖ*; ,, , *ẖ.t*, "belly."

(The feminine ending is here, as usual, neglected.)

, tank, value *š*; from , *š*, "tank."

, slope, = *q*; ,, , *q'*, "slope," "height."

(The doubled weak consonant is here neglected.)

, hand, value *d*; from , *d.t*, "hand."

, cobra, = *z*; ,, , *z.t*, "cobra."

For some alphabetic signs more than one likely origin might be found, while for others, again, no clear evidence of origin is yet forthcoming.

---

[1] "Acrophony" (giving to a sign the value of the first letter of its name) was indulged in only by priests of the latest age, inventing fantastic modes of writing their "vain repetitions" on the temple walls.

It has already been explained that the writing expresses only consonants. In the Græco-Roman period various imperfect attempts were made to render the vowels in foreign names and words by the semi-vowels as also by , the consonant *'ayin*, which originally represented, having been reduced in speech by that time to the power of *aleph* only. Thus, Πτολεμαιος is spelt *Ptwrmys*, Antoninus, *'Nt'nynws* or *Yntnyns*, &c. &c. Much earlier, throughout the New Kingdom, a special "syllabic" orthography was used for foreign names and words; according to W. Max Muller (*Asien und Europa*, 1893, chap. v.), this represents an endeavour to express the vocalization; but, if so, it was carried out with very little system.

Determinatives.—Almost any sign can be used as a determinative, but there are certain generic determinatives that are very common, *e.g.*:—

; of all actions of the mouth—eating and speaking, likewise silence, and hunger.

, ripple-lines; of liquid.

, hide; of animals, also leather, &c.

; of plants and fibres.

; of flesh.

, a sealed papyrus-roll; of books, teaching, law, and of abstract ideas generally.

Orthography.—The most primitive form of spelling in the hieroglyphic system would be by one sign for each word, and the monuments of the Ist Dynasty show a decided tendency to this mode. Examples of it in later times are preserved in the royal cartouches, for here the monumental style demanded special conciseness. Thus, for instance, the name of Thothmes III.—MN-ḪPR-R'—is spelled . (As R' is the name of the Sun-god, with customary deference to the deity it is written first though pronounced last.) A number of common words—prepositions, &c.—with only one consonant are spelled by single alphabetic signs in ordinary writing. Word-signs used singly for the names of objects are generally marked with | in classical writing, as— , *yb*, "heart," , *ḥr*, "face," &c.

But the use of bare word-signs is not common. Flexional consonants are almost always marked by phonograms, except in very early times; as when the feminine word = *z.t*, "cobra," is spelled . Also, if a sign had more than one value, a phonogram would be added to indicate which of its values was intended: thus in is *św*, "he," but in it is *śtn*, "king." Further, owing to the vast number of signs employed, to prevent confusion of one with another in rapid writing they were generally provided with "phonetic complements," a group being less easily misread than a single letter. *E.g.* , *wd*, "command," is regularly written , *wd(w)*; but , *ḥz*, "white," is written , *ḥz(z)*. Redundance in writing is the rule; for instance, *b'* is often spelled *(b)b' (')*. Biliteral phonograms are very rare as phonetic complements, nor are two biliteral phonograms employed together in writing the radicals of a word.

Spelling of words purely in phonetic or even alphabetic characters is not uncommon, the determinative being generally added. Thus in the pyramid texts we find in one copy of a text *ḫpr*, "become," written , in another . Such variant spellings are very important for fixing the readings of word-signs. It is noteworthy that though words were so freely spelled in alphabetic characters, especially in the time of the Old Kingdom, no advance was ever made towards excluding the cumbersome word-signs and biliteral phonograms, which, by a judicious use of determinatives, might well have been rendered quite superfluous.

Palæography.—*Hieroglyphic.*—The main division is into monumental or epigraphic hieroglyphs and written hieroglyphs. The former may be rendered by the sculptor or the painter in stone, on wood, &c., with great delicacy of detail, or may be simply sunk or painted in outline. When finely rendered they are of great value to the student investigating the origins of their values. No other system of writing bears upon its face so clearly the history of its development as the Egyptian; yet even in this a vast amount of work is still required to detect and disentangle the details. Monumental hieroglyphic did not cease till the 3rd century A.D. The written hieroglyphs, formed by the scribe with the reed pen on papyrus, leather, wooden tablets, &c., have their outlines more or less abbreviated, producing eventually the cursive scripts hieratic and demotic. The written hieroglyphs were employed at all periods, especially for religious texts.

*Hieratic.*—A kind of cursive hieroglyphic or hieratic writing is found even in the Ist Dynasty. In the Middle Kingdom it is well characterized, and in its most cursive form seems hardly to retain any definable trace of the original hieroglyphic pictures. The style varies much at different periods.

*Demotic.*—Widely varying degrees of cursiveness are at all periods observable in hieratic; but, about the XXVIth Dynasty, which inaugurated a great commercial era, there was something like a definite parting between the uncial hieratic and the most cursive form afterwards known as demotic. The employment of the one was thenceforth almost confined to the copying of religious texts on papyrus, while the other was used for all common purposes. Towards the end of the Ptolemaic period, though hieroglyphic and hieratic continued to be employed, demotic became the medium for writing every class of text, literary and religious works as well as the legal documents and letters, to which its use up to that time seems to have been practically limited. The cursive ligatures of old demotic had given birth to new symbols which were carefully and distinctly formed, and an epigraphic variety was engraved on stone, as in the case of the Rosetta Stone itself. One of the most characteristic distinctions of later demotic is the minuteness of the writing.

Egypt had long been bilingual when, in papyri of the 2nd century A.D., we begin to find transcripts of the Egyptian language into Greek letters: so written we have a magical text and a horoscope, probably made by foreigners or for their use. The infinite superiority of the Greek alphabet with its full notation of vowels was readily seen, but religious scruples as yet barred the way to its full adoption. The triumph of Christianity banished the old system once and for all; even at the beginning of the 4th century the native Egyptian script scarcely survived north of the Nubian frontier at Philæ; a little later it expired entirely, leaving six signs as a legacy to the Coptic alphabet.

For investigations into the origins of hieroglyphs, see Petrie's *Medum*, 1892, and the *Memoirs* of the Archæological Survey of the Egypt Exploration Fund, especially *Beni Hasan*, pt. iii., 1896; *A Collection of Hieroglyphs*, 1898; and *The Mastaba of Ptahhetep and Akhethetep*, pt. i. 1900. (F. LL. G.)

**Ehrenfeld,** formerly a town of Prussia, now united municipally with Cologne (*q.v.*). Population (1900), 26,895.

**Eibenstock,** a town of Germany, near the Mulde, 17 miles south-south-east by rail of the town and in the circle of Zwickau, kingdom of Saxony. It is a principal seat of the tambour embroidery. Population (1890), 7166; (1900), 7468.

**Eider,** a river of Prussia, in the province of Schleswig-Holstein. It rises to the south of Kiel, flows first north, then west (with wide-sweeping curves), and after a course of 117 miles enters the North Sea at Tönning. It is navigable up to Rendsburg, and is embanked through the marshes, across which in its lower course it cuts its way. The Eider Canal, constructed in 1777–84, leaves the Eider at the point where it turns to the west and enters the Bay of Kiel at Holtenau. Length, 28 miles; super-

ficial width, 100 feet; depth, $11\frac{3}{4}$ feet. It was hampered by six sluices, but was used annually by some 4000 vessels. This was in 1887–95 converted into the Emperor William Canal, for which see CANALS.

**Eiffel Tower.**—Erected for the Exposition of 1889, the Eiffel Tower, in the Champ de Mars, Paris, is by far the highest artificial structure in the world, and its height of 300 metres (1092 feet) surpasses that of the obelisk at Washington by 537 feet, and that of St Paul's Cathedral by 688 feet. Its framework is composed essentially of four uprights, which rise from the corners of a square measuring 100 metres on the side; thus the area it covers at its base is nearly $2\frac{1}{2}$ acres. These uprights are supported on huge piers of masonry and concrete, the foundations for which were carried down, by the aid of iron caissons and compressed air, to a depth of about 15 metres on the side next the Seine, and about 9 metres on the other side. At first they curve upwards at an angle of 54°; then they gradually become straighter, until they unite in a single shaft rather more than half-way up. The first platform, at a height of 57 metres, has an area of 5860 square yards, and is reached either by staircases or lifts. The next, accessible by lifts only, is 115 metres up, and has an area of 32 square yards; while the third, at 276, supports a pavilion capable of holding 800 persons. Nearly 25 metres higher up still is the lantern, with a gallery 5 metres in diameter. The work of building this structure, which is mainly composed of iron lattice-work, was begun on 28th January 1887, and the full height was reached on 13th March 1889. Besides being one of the sights of Paris, to which visitors resort in order to enjoy the extensive view that can be had from its higher galleries on a clear day, the tower is used to some extent for scientific and semi-scientific purposes; thus meteorological observations are carried on. It formed the objective in the flying-machine trials of October 1901, when M. Santos-Dumont succeeded in winning the Deutsch prize with an air-ship designed and constructed by himself. The engineer under whose direction the tower was constructed was M. ALEXANDRE GUSTAVE EIFFEL (born at Dijon on 15th December 1832), who had already had a wide experience in the construction of large metal bridges, and who designed the huge sluices for the Panama Canal, in connexion with which there were the famous scandals in 1893.

**Eilenburg,** a town of Prussia, province of Saxony, 31 miles by rail east from Halle. It has manufactures of cloth, calico, chemicals, machinery, tobacco, and baskets, quilting, and brewing. Population (1885), 11,032; (1900), 15,145.

**Einbeck,** a town of Prussia, province of Hanover, 50 miles by rail south from Hanover. The municipal antiquarian museum is preserved in the chapel (restored) of Zum Heiligen Geist. Here are an engineering school and a textile school. Population (1885), 7091; (1900), 7974.

**Eisenach,** a town of Germany, second capital of the grand duchy of Saxe-Weimar, at the north-west foot of the Thuringian Forest, 32 miles by rail west from Erfurt. The Nicolai Kirche was restored in 1887, and Georg Kirche in 1899. There are monuments to Sebastian Bach (1884), to Luther (1895), and to the war of 1870–71. The house (now museum) in which Fritz Reuter lived (1863–74), his grave in the new churchyard, and the Richard Wagner Museum should be mentioned. At Eisenach are a school of forestry, a school of design and the industrial arts, teachers' seminaries, an infirmary, and a prison. Population (1885), 19,743; (1901), 31,580.

**Eisenerz** ("Iron ore"), a market-place and old mining town in the government district of Leoben, Upper Styria, Austria, the chief centre of the Styrian iron industry. It is situated in a deep valley, dominated on the east by the Pfaffenstein (6140 feet) and on the west by the Kaiserschild (6830 feet). It has an interesting example of a mediæval fortified church, a Gothic edifice founded by Rudolph of Hapsburg in the 13th century and rebuilt in the 16th. The Erzberg, or Ore Mountain, which closes the valley on the south, furnishes such rich ore that it is quarried in the open air like stone, in the summer months. There is documentary evidence of the mines having been worked as far back as the 12th century. They afford employment to two to three thousand hands in summer and about half as many in winter, and yield some 150,000 tons of iron per annum. Eisenerz possesses, in addition, twenty-five furnaces, which produce iron, and particularly steel, of exceptional excellence. It is connected with the neighbouring mining and smelting centre of Vordernberg, at the other side of the Erzberg (3000 inhabitants), by a mountain railway on the cogged-wheel system, with an average gradient of 68 : 1000. Population (1890), 5740; (1900), 6494.

**Eisleben,** a town of Prussia, province of Saxony, 24 miles by rail west by north from Halle. It was the birthplace and deathplace of Luther, to whom a monument by Siemering was unveiled in 1883. Eisleben has a mining school, and is the seat of copper, silver, and iron mines, and of works for smelting the ore, and also produces flower and vegetable seeds. Population (1885), 23,175; (1900), 23,898.

**Ekaterinburg,** a district town of Russia, 311 miles by rail south-east of Perm, on the Iset river. It is the most important and most rapidly developing town of the Urals. Population (1860), 19,830; (1897), 55,488. It is the seat of the central mining administration, and has a mining chemical laboratory for the assay of gold extracted both in the Urals and Siberia, a mining school, an Imperial stone-cutting factory, the Ural Society of Naturalists, a first-class magnetic and meteorological observatory, and many banks. Altogether, it is one of the best provincial towns of Russia. There are, besides, one large steam flour mill, candle works, several machinery works, woollen mills, paper works, soap works, and tanneries, and many stone-cutting factories and workshops, the produce of which is widely exported. Altogether, over 2000 persons work in the factories, and nearly as many in the workshops. Many of the residents are engaged in gold mining. The trade in goods exported from the Urals and imported from Russia is very large, and two important fairs are held. Nearly 40 gold and platinum mines, 32 iron works, and numbers of other works and factories are scattered in the district, while wheels, travelling boxes, all sorts of hardware, boots, and so on are fabricated on a great scale in the villages.

**Ekaterinodar,** a town of Russia, North Caucasia, capital of the province of Kubañ, situated on the right bank of the Kubañ, 531 miles north-west of Tiflis, on the railway from Rostov to Novorossiysk, 85 miles by rail from this seaport. Founded in 1794 as a small fort, its population has grown from 9620 in 1860 to 65,700 in 1897. It has gymnasia for boys and girls, various professional schools, an experimental fruit-farm, and a natural history museum. A considerable trade, especially in grain, is carried on by its merchants.

**Ekaterino-Nikolskaya,** a Cossack village of Russia, province of the Amur, 340 miles below Blagovyeschensk, at the spot where the Amur enters a gorge through which it pierces the Little Khingan. The road which runs along the middle Amur ends at this spot, and when the

river carries ice in spring and winter, all communication with the lower Amur is practically interrupted there. It is the centre of government for the Amur Cossacks. Population, about 2000.

**Ekaterinoslav,** a province of South Russia, having Poltava and Kharkoff on the N., the Don province on the E., the Sea of Azov and Taurida on the S., and Khersoñ on the W. Area, 24,478 square miles. Its surface is undulating prairie gently sloping south and north, with a few hills reaching 1320 ft. in the north-east, where a gentle swelling (the Don Hills) compels the Don to make a great curve eastwards. Another row of hills, to which the eastward bend of the Dnieper is due, rises in the west. These hills have a crystalline core (granites, syenites, and diorites), while the surface strata are Carboniferous, Permian, Cretaceous, and Tertiary. The province is rich in minerals, especially in anthracite and coal, iron ores, and rock-salt. Granite, limestone, grindstone, slate, as also graphite, manganese, and mercury, are found. It is watered by the Dnieper, the Don, and their tributaries, and several affluents of the Sea of Azov. The soil is a very fertile black earth, but the crops have occasionally to suffer from droughts—the average yearly rainfall being only 15 inches. Forests are scarce. Population (1860), 1,138,750; (1897), 2,112,651—chiefly Little Russians, partly Great Russians, and some Greeks. The land is owned as follows: the peasants hold in communal ownership 37 per cent., and in private ownership 4 per cent.; nobility, 31 per cent.; German colonists, 9·5 per cent.; Greeks, 7 per cent.; the remainder being owned by various persons and companies.

Wheat is grown extensively with the aid of modern machinery, and the average crops are 7,580,000 quarters of various cereals, 577,000 quarters of potatoes, and about 1000 cwt. of tobacco. Vines have been grown lately. There were in 1895, 295,670 horses, 653,770 horned cattle, and 2,174,350 sheep—nearly 6700 tons of raw wool being obtained every year. Mining attains every year more and more importance, the returns in South Russia (Ekaterinoslav and Don) being, in 1896, coal from 83 mines, 2,926,000 tons (12,000 workers); iron ore from 19 mines, 1,208,000 tons; manganese ore (4 mines), 45,550 tons; iron (all in Ekaterinoslav), 608,600 tons; steel, 51,100 tons; rails, 246,000 tons; iron goods, 50,000 tons. Besides, mercury, ore, and fireclay are extracted. Nearly 40,000 persons find occupation in factories, of which the iron works and the 34 agricultural machinery works are the most important, while in the district of Mariupol the making of agricultural implements and machinery has undergone a very great extension as a domestic industry in the villages. Grain is exported to a very large extent (about 950,000 tons, and 520,000 tons in transit), *viâ* the Dnieper, the Sebastopol railway, and the port of Mariupol. Nearly 4000 boats and 1000 rafts are loaded and unloaded every year, carrying over 2,000,000 tons of goods (value 13,000,000 roubles), and giving occupation to 27,000 men. The port of Mariupol is visited every year by about 80 steamers and 40 sailing vessels engaged in foreign trade, and 1600 vessels engaged in coasting. The government is better provided with schools, gymnasia, professional and primary, than many other governments of Russia. The chief towns of its 8 districts are: Ekaterinoslav (121,216 inhabitants), Alexandrovsk (16,393), Bakhmut (19,416), Mariupol (31,772), Novomoskovsk (12,862), Pavlograd (17,188), Slavyanoserbsk (3120), and Verkhnednyeprovsk (11,607).

(P. A. K.)

**Ekaterinoslav,** capital of the above province, on the right bank of the Dnieper, 607 miles by rail south-south-west of Moscow. It is a rapidly growing town, well provided with schools, including a number of professional ones, and is an important depot for timber shipped down the Dnieper, as also for grain. Its iron works, steam flour-mills, and agricultural machinery works give occupation to 5000 workers. Considerable trade is carried on in cattle, grain, and raw wool. Population (1861), 18,881, without suburbs; (1897), 121,216.

**Elabuga,** a district town of Russia, government and 279 miles south-east of Vyatka, on Kama river, near its junction with Totma. It has steam flour-mills, and carries on a brisk trade in exporting corn. Population, 9776.

The famous *Ananiinskiy Moghilnik* (burial-place) is on the right bank of the Kama, 3 miles from above the town. It was discovered in 1858, was excavated by Alabin, Lerch, and Nevostruyeff, in charge of the Archæological Commission, and has since supplied extremely valuable collections of archæological objects belonging to the Stone, Bronze, and Iron Ages. It represented first a mound, about 500 feet in circumference, adorned with decorated stones (which have disappeared), and contained an inner wall, 65 feet in circumference, made of uncemented stone flags. Nearly 50 skeletons were discovered in it, mostly laid upon burned logs, surrounded with pots filled with partially burned bones. A great variety of bronze decorations and glazed clay pearls were strewn round the skeletons. The knives, daggers, and arrow-points are of slate, bronze, and iron, the two last being very rough imitations of stone implements. On one of the funeral flags the image of a man, without moustaches or beard, dressed in a costume and helmet recalling those of the Circassians, was discovered. The exact period of these funeral mounds is not known.

**Elastic Systems.**—In the article ELASTICITY (*Ency. Brit.* vol. vii.) there is an outline of the general mathematical theory of Elasticity, and an account of the results obtained by applying it to the solution of the very important problem of the torsion of prisms. The present article is meant to supplement the former one by giving an account of some of the results that have been arrived at in the application of the theory to other problems.

1. *Flexure of a Beam.*—The simple theory of the bending of a beam by applied couples has been explained in the original article, §§ 57–62. If M is the couple, the central line of the beam is bent into a circle of radius EI/M, where E is the Young's modulus of the material, and I is the moment of inertia of the cross-section about the axis through its centroid at right angles to the plane of flexure. This plane is supposed to contain one principal axis of inertia of each cross-section,[1] and the locus of the perpendicular principal axes after flexure is a surface cutting the plane of flexure at right angles and known as the "neutral surface"; the traces of this surface are dotted in Fig. 1. The quantity EI is known as the "flexural rigidity." The applied couple M is balanced at any section by a couple arising from the stress exerted across the section. Supposing, to fix ideas, that the curve into which the central line is bent is concave downwards, the stress at any point above (below) the neutral surface is simple longitudinal tension (pressure) of amount per unit area equal to the product of M/I and the distance of the point from the neutral surface. The corresponding strain consists of extension (contraction) of the longitudinal fibres above (below) the neutral surface accompanied by lateral contraction (extension) of the perpendicular fibres, and the effect of the lateral strain is seen in the change of shape of the section producing the anticlastic curvature of the beam (cf. ELASTICITY, *Ency. Brit.* vol. vii. p. 809). The extension (contraction) of a longitudinal fibre distant $y$ above (below) the neutral surface is $My/EI$, and the lateral contraction (extension) is $\sigma My/EI$, where $\sigma$ is the "Poisson's ratio" of the material (a fraction nearly equal to $\frac{1}{4}$ for most hard solids). The displacements produced are—(1) a deflexion of the central line by which the centroid of each cross-

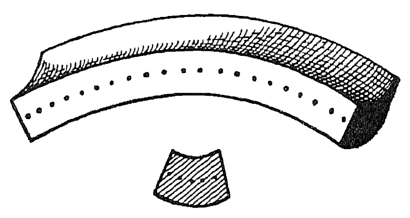

Fig. 1.

[1] When this is the case the beam is said to be bent in a "principal plane."

section comes to its proper place on the curved central line; (2) a rotation of the plane of each cross-section about the axis through its centroid at right angles to the plane of flexure, of such an amount as to place it at right angles to the curved central line; (3) a distortion of the shape of each cross-section in its own plane producing the anticlastic curvature.

2. That this theory requires modification when the load does not consist simply of terminal couples can be seen most easily by considering the problem of a beam loaded at one end with a weight W, and supported in a horizontal position at its other end. The forces that are exerted at any section $p$, to balance the weight W, must reduce statically to a vertical force W and a couple, and these forces arise from the action of the part A$p$ on the part B$p$ (see Fig. 2), *i.e.*, from the stresses across the section at $p$. The stress that suffices in the simpler problem gives rise to no vertical force, and it is clear that in addition to longitudinal tensions and pressures there must be shearing stresses at the cross-sections. The determination of the character of these, and of the corresponding strains and displacements, was effected by Saint-Venant and Clebsch for a number of forms of sections by means of an analysis of the same kind as that employed in the solution of the torsion problem.

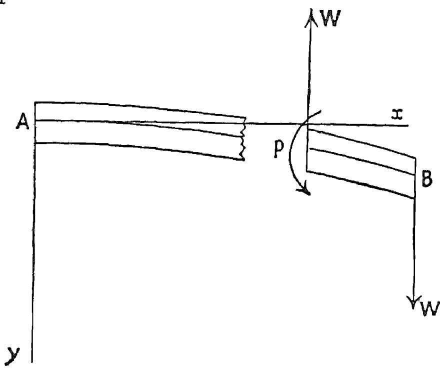

Fig. 2.

3. Let $l$ be the length of the beam, $x$ the distance of the section $p$ from the fixed end A, $y$ the distance of any point below the horizontal plane through the centroid of the section at A, then the bending moment at $p$ is $W(l-x)$, and the longitudinal tension P at any point on the cross-section is $-W(l-x)y/I$, and this is related to the bending moment exactly as in the simpler problem.

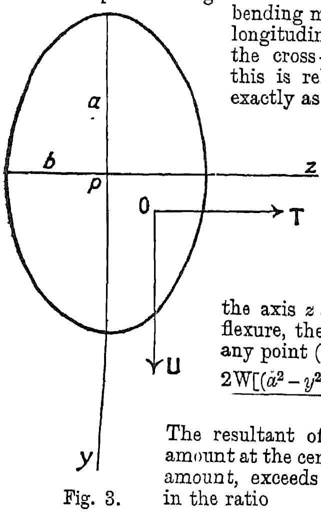

Fig. 3.

4. The expressions for the shearing stresses depend on the shape of the cross-section. Taking the beam to be of isotropic material and the cross-section to be an ellipse of semiaxes $a$ and $b$ (Fig. 3), the $a$ axis being vertical in the unstrained state, and drawing the axis $z$ at right angles to the plane of flexure, the vertical shearing stress U at any point $(y, z)$ on any cross-section is

$$\frac{2W[(a^2-y^2)\{2a^2(1+\sigma)+b^2\}-z^2a^2(1-2\sigma)]}{\pi a^3 b(1+\sigma)(3a^2+b^2)}.$$

The resultant of these stresses is W, but the amount at the centroid, which is the maximum amount, exceeds the average amount, $W/\pi ab$, in the ratio

$$\{4a^2(1+\sigma)+2b^2\}/(3a^2+b^2)(1+\sigma).$$

Taking $\sigma=\frac{1}{4}$, this ratio is $\frac{7}{5}$ for a circle, nearly $\frac{4}{3}$ for a flat elliptic bar with the longest diameter vertical, nearly $\frac{8}{5}$ for a flat elliptic bar with the longest diameter horizontal.

In the same problem the horizontal shearing stress T at any point on any cross-section is of amount

$$-\frac{4Wyz\{a^2(1+\sigma)+b^2\sigma\}}{\pi a^3 b(1+\sigma)(3a^2+b^2)}.$$

The resultant of these stresses vanishes; but, taking as before $\sigma=\frac{1}{4}$, and putting for the three cases above $a=b$, $a=10b$, $b=10a$, the ratio of the maximum of this stress to the average vertical shearing stress has the values $\frac{3}{5}$, nearly $\frac{1}{15}$, and nearly 4. Thus the stress T is of considerable importance when the beam is a plank.

As another example we may consider a circular tube of external radius $r_0$ and internal radius $r_1$. We find

$$\left.\begin{aligned}
P &= -\frac{4W}{\pi(r_0^4-r_1^4)}(l-x)y,\\
U &= \frac{W}{2(1+\sigma)\pi(r_0^4-r_1^4)}\Big[(3+2\sigma)\Big\{r_0^2+r_1^2-y^2\\
&\qquad -\frac{r_0^2 r_1^2}{(y^2+z^2)^2}(y^2-z^2)\Big\}-(1-2\sigma)z^2\Big]\\
T &= -\frac{W}{(1+\sigma)\pi(r_0^4-r_1^4)}\Big\{1+2\sigma+(3+2\sigma)\frac{r_0^2 r_1^2}{(y^2+z^2)^2}\Big\}yz;
\end{aligned}\right\}$$

and for a tube of radius $r$ and small thickness $t$ the value of P and the maximum values of U and T reduce approximately to

$$P = -W(l-x)y/\pi r^3 t$$
$$U_{max} = W/\pi rt,\quad T_{max} = W/2\pi rt.$$

The greatest value of U is in this case approximately twice its average value, but it is possible that these results for the bending of very thin tubes may be seriously at fault if the tube is not plugged, and if the load is not applied in the manner contemplated in the theory (cf. § 9). In such cases the extensions and contractions of the longitudinal fibres may be practically confined to a small part of the material near the ends of the tube, while the rest of the tube is deformed without stretching.

5. The shearing stresses U, T on the cross-sections are necessarily accompanied by shearing stresses on the longitudinal sections, and on each such section the shearing stress is parallel to the central line; on a vertical section $z=$ const. its amount at any point is T, and on a horizontal section $y=$ const. its amount at any point is U.

The internal stress at any point is completely determined by the components P, U, T, but these are not *principal stresses*. Clebsch has given an elegant geometrical construction for determining the principal stresses at any point when the values of P, U, T are known.

From the point O (Fig. 4) draw lines OP, OU, OT, to represent the stresses P, U, T at O, on the cross-section through O, in magnitude, direction and sense, and compound U and T into a resultant represented by OE; the plane EOP is a principal plane of stress at O, and the principal stress at right angles to this plane vanishes. Take M the middle point of OP, and with centre M and radius ME describe a circle cutting the line OP in A and B; then OA and OB represent the magnitudes of the two remaining principal stresses. On AB describe a rectangle ABDC so that DC passes through E; then OC is the direction of the principal stress represented in magnitude by OA, and OD is the direction of the principal stress represented in magnitude by OB.

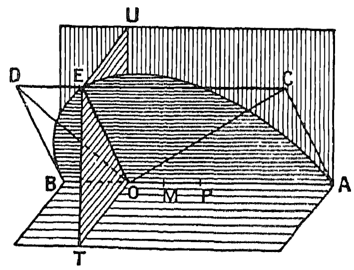

Fig. 4.

6. As regards the strain in the beam, the longitudinal and lateral extensions and contractions depend on the bending moment in the same way as in the simpler problem; but, the bending moment being variable, the anticlastic curvature produced is also variable. In addition to these extensions and contractions there are shearing strains corresponding to the shearing stresses T, U. The shearing strain corresponding to T consists of a relative sliding parallel to the central line of different longitudinal linear elements combined with a relative sliding in a transverse horizontal direction of elements of different cross-sections; the latter of these is concerned in the production of those displacements by which the variable anticlastic curvature is brought about; to see the effect of the former we may most suitably consider for the case of an elliptic cross-section the distortion of the shape of a rectangular portion

of a plane of the material which in the natural state was horizontal; all the boundaries of such a portion become parabolas of small curvature, which is variable along the length of the beam, and the particular effect under consideration is the change of the transverse horizontal linear elements from straight lines such as HK to parabolas such as H′K′ (Fig. 5); the lines HL and KM are parallel to the central line, and the figure is drawn for a plane above the neutral plane. When the cross-section is not an ellipse the character of the strain is the same, but the curves are only approximately parabolic.

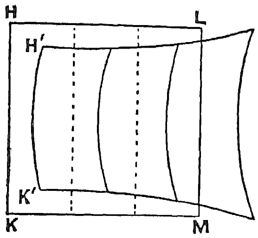

Fig. 5.

The shearing strain corresponding to U is a distortion which has the effect that the straight vertical filaments become curved lines which cut the longitudinal filaments obliquely, and thus the cross-sections do not remain plane, but become curved surfaces, and the tangent plane to any one of these surfaces at the centroid cuts the central line obliquely (Fig. 6). The angle between these tangent planes and the central line is the same at all points of the line; and, denoting it by $\frac{1}{2}\pi + s_0$, the value of $s_0$ is expressible as

$$\frac{\text{shearing stress at centroid}}{\text{rigidity of material}},$$

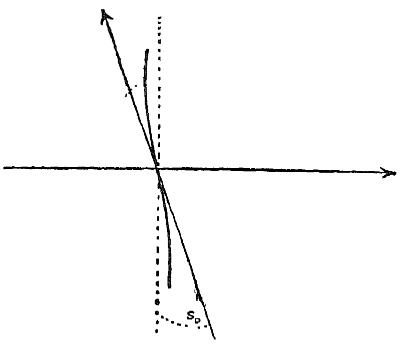

Fig. 6.

and it thus depends on the shape of the cross-section; for the elliptic section of § 4 its value is

$$\frac{4W}{E\pi ab}\,\frac{2a^2(1+\sigma)+b^2}{3a^2+b^2};$$

for a circle with $\sigma=\frac{1}{4}$, this becomes $7W/2E\pi a^2$. The vertical filament through the centroid of any cross-section becomes a cubical parabola, as shown in Fig. 6, and the contour lines of the curved surface into which any cross-section is distorted are shown in Fig. 7 for a circular section.

7. The deflexion of the beam is determined from the equation

curvature of central line = bending moment ÷ flexural rigidity,

and the special conditions at the supported end; there is no alteration of this statement on account of the shears. As regards the special condition at an end which is *encastrée*, or built-in, Saint-Venant proposed to assume that the central tangent plane of the cross-section at the end is vertical; with this assumption the tangent to the central line at the end is inclined downwards and makes an angle $s_0$ with the horizontal (see Fig. 8); it is, however, improbable that this condition is exactly realized in practice. In the application of the theory to the experimental determination of Young's modulus, the small angle which the central line at the support makes with the horizontal is an unknown quantity, to be eliminated by observation of the deflexion at two or more points.

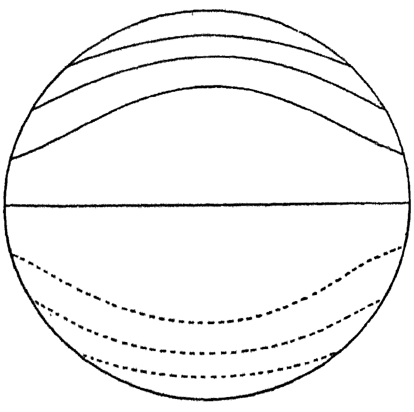

Fig. 7.

8. We may suppose the displacement in a bent beam to be produced by the following operations: (1) the central line is deflected into its curved form, (2) the cross-sections are rotated about axes through their centroids at right angles to the plane of flexure so as to make angles equal to $\frac{1}{2}\pi + s_0$ with the central line, (3) each cross-section is distorted in its own plane in such a way that the appropriate variable anticlastic curvature is produced, (4) the cross-sections are further distorted into curved surfaces. The contour lines of Fig. 7 show the disturbance from the central tangent plane, not from the original vertical plane.

9. *Practical Application of Saint-Venant's Theory.*—The theory above described is exact provided the forces applied to the loaded end, which have W for resultant, are distributed over the terminal section in a particular way, not likely to be realized in practice; and the application to practical problems depends on a principle due to Saint-Venant, to the effect that, except for comparatively small portions of the beam near to the loaded and fixed ends, the resultant only is effective, and its mode of distribution does not seriously affect the internal strain and stress. In fact, the actual stress is that due to forces with the required resultant distributed in the manner contemplated in the theory, superposed upon that due to a certain distribution of forces on each terminal section which, if applied to a rigid body, would keep it in equilibrium; according to Saint-Venant's principle, the stresses and strains due to such distributions of force are unimportant except near the ends. For this principle to be exactly applicable it is necessary that the length of the beam should be very great compared with any linear dimension of its cross-section; for the practical application it is sufficient that the length should be about ten times the greatest diameter.

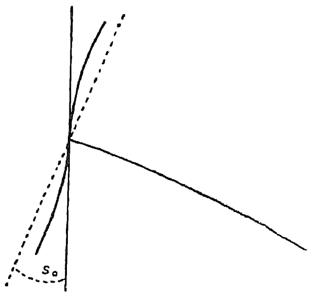

Fig. 8.

10. The theoretical determination of the stress in a bent beam under conditions as to load and support other than those considered in §§ 2–8 is attended by difficulties which have not yet been surmounted, but the equation for the deflexion

curvature of central line = bending moment ÷ flexural rigidity

is sufficiently exact whenever the length is a considerable multiple of the greatest diameter of the cross-section. This result is indicated by the theories of indefinitely thin wires developed by Kirchhoff and Boussinesq, and has been confirmed by special researches made by Pochhammer and Pearson. The equation for the deflexion above written is the basis of the treatment of continuous beams resting on three or more supports and carrying distributed loads. The calculation of the bending moment can be replaced by a method of graphical construction, due to Mohr, and depending on the two following theorems:—

(I.) The curve of the central line of each span of a

beam, when the bending moment M is given,[1] is identical with the catenary or funicular curve passing through the ends of the span under a (fictitious) load per unit length of the span equal to M/EI, the horizontal tension in the funicular being unity.

(II.) The directions of the tangents to this funicular curve at the ends of the span are the same for all statically equivalent systems of (fictitious) load.

When M is known, the magnitude of the resultant shearing stress at any section is $dM/dx$, where $x$ is measured along the beam.

11. Let $l$ be the length of a span of a loaded beam (Fig. 9), $M_1$ and $M_2$ the bending moments at the ends, M the bending moment at a section distant $x$ from the end ($M_1$), M′ the bending moment at

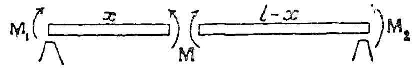

Fig. 9.

the same section when the same span with the same load is simply supported; then M is given by the formula

$$M = M' + M_1\frac{l-x}{l} + M_2\frac{x}{l},$$

and thus a fictitious load statically equivalent to M/EI can be easily found when M′ has been found. If we draw a curve (Fig. 10) to pass through the ends of the span, so that its ordinate represents the value of M′/EI, the corresponding fictitious loads are statically equivalent to a single load, of amount represented by the area of the curve, placed at the point of the span vertically above the centre of gravity of this area. If PN is the ordinate of this curve, and if at the ends of the span we erect ordinates in the proper sense to represent $M_1$/EI and $M_2$/EI, the bending moment at any point is represented by the length PQ.[2] For a uniformly distributed load the curve of M′ is a parabola $M' = \frac{1}{2}wx(l-x)$, where $w$ is the load per unit of length; and the statically equivalent fictitious load is $\frac{1}{12}wl^3$/EI placed at the middle point G of the span; also the loads statically equivalent to the fictitious loads $M_1(l-x)/l$EI and $M_2x/l$EI are $\frac{1}{3}M_1l$/EI and $\frac{1}{3}M_2l$/EI placed at the points $g$, $g'$ of trisection of the span. The funicular polygon for

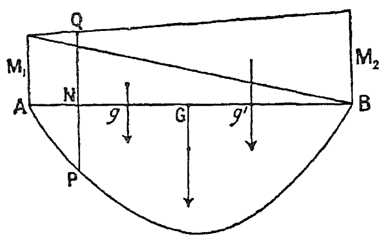

Fig. 10.

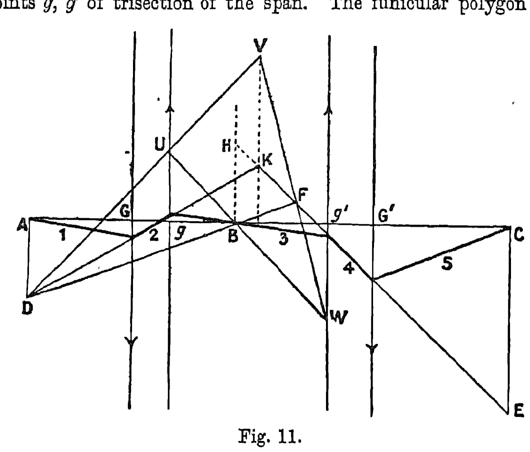

Fig. 11.

the fictitious loads can thus be drawn, and the direction of the central line at the supports is determined when the bending moments at the supports are known.

[1] The sign of M is shown by the arrow-heads in Fig. 9, for which, with $y$ downwards,

$$EI\frac{d^2y}{dx^2} + M = 0.$$

[2] The figure is drawn for a case where the bending moment has the same sign throughout.

12. When there is more than one span the funiculars in question may be drawn for each of the spans, and, if the bending moments at the ends of the extreme spans are known, the intermediate ones can be determined. This determination depends on two considerations: (1) the fictitious loads corresponding to the bending moment at any support are proportional to the lengths of the spans which abut on that support; (2) the sides of two funiculars that end at any support coincide in direction. Fig. 11 illustrates the method for the case of a uniform beam on three supports A, B, C, the ends A and C being freely supported. There will be an unknown bending moment $M_0$ at B, and the system[3] of fictitious loads is $\frac{1}{12}w\mathrm{AB}^3$/EI at G the middle point of AB, $\frac{1}{12}w\mathrm{BC}^3$/EI at G′ the middle point of BC, $-\frac{1}{3}M_0\mathrm{AB}$/EI at $g$ and $-\frac{1}{3}M_0\mathrm{BC}$/EI at $g'$, where $g$ and $g'$ are the points of trisection nearer to B of the spans AB, BC. The centre of gravity of the two latter is a fixed point independent of $M_0$, and the line VK of the figure is the vertical through this point. We draw AD and CE to represent the loads at G and G′ in magnitude; then D and E are fixed points. We construct any triangle UVW whose sides UV, UW pass through D, B, and whose vertices lie on the verticals $g$U, VK, $g'$W; the point F where VW meets DB is a fixed point, and the lines EF, DK are the two sides (2, 4) of the required funiculars which do not pass through A, B, or C. The remaining sides (1, 3, 5) can then be drawn, and the side 3 necessarily passes through B; for the triangle UVW and the triangle whose sides are 2, 3, 4 are in perspective.

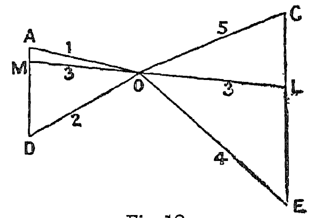

Fig. 12.

The bending moment $M_0$ is represented in the figure by the vertical line BH where H is on the continuation of the side 4, the scale being given by

$$\frac{\mathrm{BH}}{\mathrm{CE}} = \frac{\frac{1}{2}M_0\mathrm{BC}}{\frac{1}{12}w\mathrm{BC}^3};$$

this appears from the diagrams of forces, Fig. 12, in which the oblique lines are marked to correspond to the sides of the funiculars to which they are parallel.

In the application of the method to more complicated cases there are two systems of fixed points corresponding to F, by means of which the sides of the funiculars are drawn.

13. *Finite Bending of Thin Rod.*—The equation

curvature = bending moment ÷ flexural rigidity

may also be applied to the problem of the flexure in a principal plane of a very thin rod or wire, for which the curvature need not be small. When the forces that produce the flexure are applied at the ends only, the curve into which the central line is bent is one of a definite family of curves, to which the name *elastica* has been given, and there is a division of the family into two species according as the external forces are applied directly to the ends or are applied to rigid arms attached to the ends; the curves of the former species are characterized by the presence of inflexions at all the points at which they cut the line of action of the applied forces.

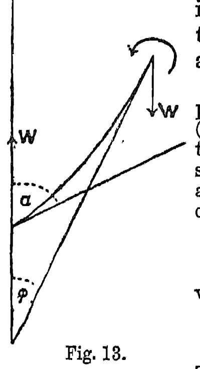

Fig. 13.

Selecting this case for consideration, the problem of determining the form of the curve (cf. Fig. 13) is mathematically identical with the problem of determining the motion of a simple circular pendulum oscillating through a finite angle, as is seen by comparing the differential equation of the curve

$$EI\frac{d^2\phi}{ds^2} + W\sin\phi = 0$$

with the equation of motion of the pendulum

$$l\frac{d^2\phi}{dt^2} + g\sin\phi = 0.$$

The length L of th curve between two inflexions corresponds to the time of oscillation of the pendulum from rest to rest, and we thus have

$$L\sqrt{(W/EI)} = 2K,$$

where K is the real quarter period of elliptic functions of modulus

[3] $M_0$ is taken to have, as it obviously has, the opposite sense to that shown in Fig. 9.

$\sin\frac{1}{2}\alpha$, and $\alpha$ is the angle at which the curve cuts the line of action of the applied forces. Unless the length of the rod exceeds $\pi\sqrt{(EI/W)}$ it will not bend under the force, but when the length is great enough there may be more than two points of inflexion and more than one bay of the curve; for $n$ bays ($n+1$ inflexions) the length must exceed $n\pi\sqrt{(EI/W)}$. Some of the forms of the curve are shown in Fig. 14.

For the form $d$, in which two bays make a figure of eight, we have

$$L\sqrt{(W/EI)}=4{\cdot}6, \ \alpha=130^\circ$$

approximately (see Hess, *Math. Ann.* xxiii., 1884). It is noteworthy that whenever the length and force admit of a sinuous form, such as $a$ or $b$, with more than two inflexions, there is also possible a crossed form, like $c$, with two inflexions only; it is probable that the latter form is stable and the former unstable.

14. The particular case of the above for which $\alpha$ is very small is a curve of sines of small amplitude, and the result in this case has been applied to the problem of the buckling of struts under thrust. When the strut, of length L′, is maintained upright at its lower end, and loaded at its upper end, it is simply compressed, unless

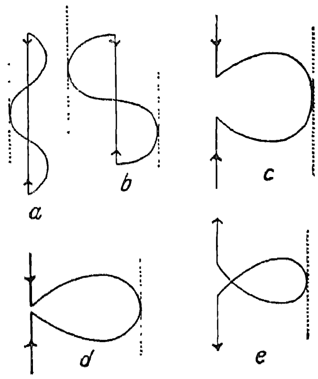

Fig. 14

$$L'^2W>\tfrac{1}{4}\pi^2EI;$$

for the lower end corresponds to a point at which the tangent is vertical on an elastica for which the line of inflexions is also vertical, and thus the length must be half of one bay (Fig. 15, $a$). For greater lengths or loads the strut tends to bend or buckle under the load; for a very slight excess of $L'^2W$ above $\frac{1}{4}\pi^2EI$, the theory on which the above discussion is founded, is not quite adequate, as it assumes the central line of the strut to be free from extension or contraction, and it is probable that bending without extension does not take place when the length or the force exceeds the critical value but slightly. It should be noted also that the formula has no application to short struts, as the theory from which it is derived is founded on the assumption that the length is great compared with the diameter (cf. § 10).

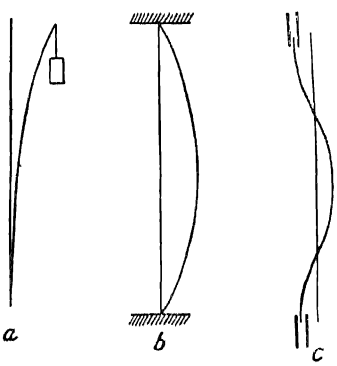

Fig. 15.

The condition of buckling, corresponding to the above, for a long strut, of length L′, when both ends are free to turn is $L'^2W>\pi^2EI$; for the central line forms a complete bay (Fig. 15, $b$); if both ends are maintained in the same vertical line, the condition is $L'^2W>4\pi^2EI$, the central line forming a complete bay and two half bays (Fig. 15, $c$).

15. In our consideration of flexure it has so far been supposed that the bending takes place in a principal plane. We may remove this restriction by resolving the forces that tend to produce bending into systems of forces acting in the two principal planes. To each plane there corresponds a particular flexural rigidity, and the systems of forces in the two planes give rise to independent systems of stress, strain, and displacement, which must be superposed in order to obtain the actual state. Applying this process to the problem of §§ 2–8, and supposing that one principal axis of a cross-section at its centroid makes an angle $\theta$ with the vertical, then for any shape of section the neutral surface or locus of unextended fibres cuts the section in a line DD′, which is conjugate to the vertical diameter CP with respect to any ellipse of inertia of the section. The central line is bent into a plane curve which is not in a vertical plane, but is in a plane through the line CY which is perpendicular to DD′ (Fig. 16).

16. *Bending and Twisting of Thin Rods.*—When a very thin rod or wire is bent and twisted by applied forces, the forces on any part of it limited by a normal section are balanced by the stresses across the section, and these stresses are statically equivalent to certain forces and couples at the centroid of the section; we shall call them the *stress-resultants* and the *stress-couples*. The stress-couples consist of two flexural couples in the two principal

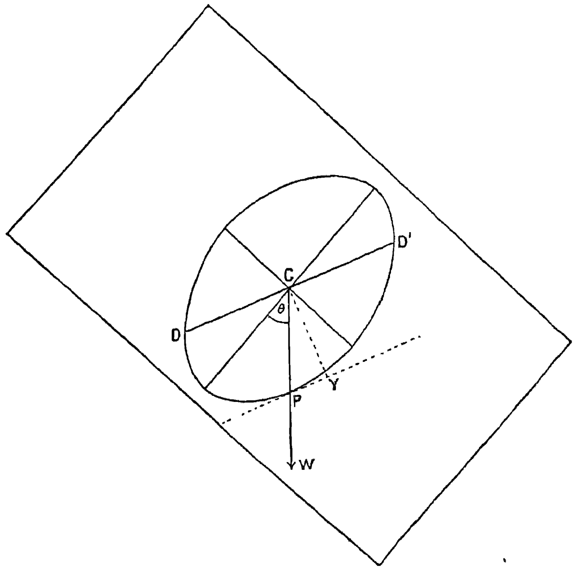

Fig. 16.

planes, and the torsional couple about the tangent to the central line. The torsional couple is the product of the torsional rigidity and the twist produced; the torsional rigidity is exactly the same as for a straight rod of the same material and section twisted without bending, as in Saint-Venant's torsion problem (ELASTICITY, *Ency. Brit.* vol. vii. p. 812). The twist $\tau$ is connected with the deformation of the wire in this way: if we suppose a very small ring which fits the cross-section of the wire to be provided with a pointer in the direction of one principal axis, and to move along the wire with velocity $v$, the pointer will rotate about the central line with angular velocity $\tau v$. The amount of the flexural couple for either principal plane at any section is the product of the flexural rigidity for that plane, and the resolved part in that plane of the curvature of the central line at the centroid of the section; the resolved part of the curvature along the normal to any plane is obtained by treating the curvature as a vector directed along the normal to the osculating plane and projecting this vector. The flexural couples reduce to a single couple in the osculating plane proportional to the curvature when the two flexural rigidities are equal, and in this case only.

The stress-resultants across any section are shearing stresses in the two principal planes, and a tension or thrust along the central line; when the stress-couples and the applied forces are known these stress-resultants are determinate. The existence in particular of the resultant tension or thrust parallel to the central line does not imply sensible extension or contraction of the central filament, and the tension per unit area of the cross-section to which

it would be equivalent is small compared with the tensions and pressures in longitudinal filaments not passing through the centroid of the section; the moments of the latter tensions and pressures constitute the flexural couples.

17. We consider, in particular, the case of a naturally straight spring or rod of circular section, radius $c$, and of homogeneous isotropic material. The torsional rigidity is $\frac{1}{4}E\pi c^4/(1+\sigma)$; and the flexural rigidity, which is the same for all planes through the central line, is $\frac{1}{4}E\pi c^4$; we shall denote these by C and A respectively. The rod may be held bent by suitable forces into a curve of double curvature with an amount of twist $\tau$, and then the torsional couple is $C\tau$, and the flexural couple in the osculating plane is $A/\rho$, where $\rho$ is the radius of circular curvature. Among the curves in which the rod can be held by forces and couples applied at its ends only, one is a circular helix; and then the applied forces and couples are equivalent to a wrench about the axis of the helix.

Let $\alpha$ be the angle and $r$ the radius of the helix, so that $\rho$ is $r\sec^2\alpha$; and let R and K be the force and couple of the wrench (Fig. 17).

Then the couple formed by R and an equal and opposite force at any section and the couple K are equivalent to the torsional and flexural couples at the section, and this gives the equations for R and K

$$R=A\frac{\sin\alpha\cos^2\alpha}{r^2}-C\tau\frac{\cos\alpha}{r},$$

$$K=A\frac{\cos^3\alpha}{r}+C\tau\sin\alpha.$$

The thrust across any section is $R\sin\alpha$ parallel to the tangent to the helix, and the shearing stress-resultant is $R\cos\alpha$ at right angles to the osculating plane.

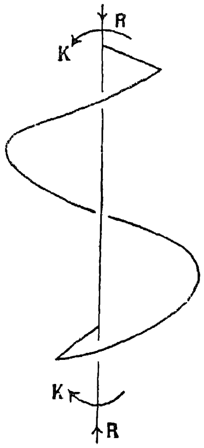

Fig. 17.

When the twist is such that, if the rod were simply unbent, it would also be untwisted, $\tau$ is $\sin\alpha\cos\alpha/r$, and then, restoring the values of A and C, we have

$$R=\frac{E\pi c^4}{4r^2}\frac{\sigma}{1+\sigma}\sin\alpha\cos^2\alpha,$$

$$K=\frac{E\pi c^4}{4r}\frac{1+\sigma\cos^2\alpha}{1+\sigma}\cos\alpha.$$

18. The theory of spiral springs affords an application of these results. The stress-couples called into play when a naturally helical spring $(\alpha, r)$ is held in the form of a helix $(\alpha', r')$, are equal to the differences between those called into play when a straight rod of the same material and section is held in the first form, and those called into play when it is held in the second form.

Thus the torsional couple is

$$C\left(\frac{\sin\alpha'\cos\alpha'}{r'}-\frac{\sin\alpha\cos\alpha}{r}\right),$$

and the flexural couple is

$$A\left(\frac{\cos^2\alpha'}{r'}-\frac{\cos^2\alpha}{r}\right).$$

The wrench (R, K) along the axis by which the spring can be held in the form $(\alpha', r')$ is given by the equations

$$R=A\frac{\sin\alpha'}{r'}\left(\frac{\cos^2\alpha'}{r'}-\frac{\cos^2\alpha}{r}\right)-C\frac{\cos\alpha'}{r'}\left(\frac{\sin\alpha'\cos\alpha'}{r'}-\frac{\sin\alpha\cos\alpha}{r}\right),$$

$$K=A\cos\alpha'\left(\frac{\cos^2\alpha'}{r'}-\frac{\cos^2\alpha}{r}\right)+C\sin\alpha'\left(\frac{\sin\alpha'\cos\alpha'}{r'}-\frac{\sin\alpha\cos\alpha}{r}\right).$$

When the spring is slightly extended by an axial force $F, =-R$, and there is no couple, so that K vanishes, and $\alpha'$, $r'$, differ very little from $\alpha$, $r$, it follows from these equations that the axial elongation, $\delta x$, is connected with the axial length $x$ and the force F by the equation

$$F=\frac{E\pi c^4}{4r^2}\frac{\sin\alpha}{1+\sigma\cos^2\alpha}\frac{\delta x}{x},$$

and that the loaded end is rotated about the axis of the helix through a small angle

$$\frac{4\sigma Fxr\cos\alpha}{E\pi c^4},$$

the sense of the rotation being such that the spring becomes more tightly coiled.

19. A horizontal pointer attached to a vertical spiral spring would be made to rotate by loading the spring, and the angle through which it turns might be used to measure the load, at any rate, when the load is not too great; but a much more sensitive contrivance is the twisted strip devised by Ayrton and Perry. A very thin, narrow rectangular strip of metal is given a permanent twist about its longitudinal middle line, and a pointer is attached to it at right angles to this line. When the strip is subjected to longitudinal tension the pointer rotates through a considerable angle. Bryan (*Phil. Mag.*, December 1890) has succeeded in constructing a theory of the action of the strip, according to which it is regarded as a strip of *plating* in the form of a right helicoid, which, after extension of the middle line, becomes a portion of a slightly different helicoid; on account of the thinness of the strip, the change of curvature of the surface is considerable, even when the extension is small, and the pointer turns with the generators of the helicoid.

Taking $b$ for the breadth and $t$ for the thickness of the strip, and $\tau$ for the permanent twist, the approximate formula for the angle $\theta$ through which the strip is untwisted on the application of a load W was found to be

$$\theta=\frac{Wb\tau(1+\sigma)}{2Et^3\left(1+\frac{(1+\sigma)}{30}\frac{b^4\tau^2}{t^2}\right)}.$$

The quantity $b\tau$ which occurs in the formula is the total twist in a length of the strip equal to its breadth, and this will generally be very small; if it is small of the same order as $t/b$, or a higher order, the formula becomes $\frac{1}{2}Wb\tau(1+\sigma)/Et^3$, with sufficient approximation, and this result appears to be in agreement with observations of the behaviour of such strips.

20. *General Theorems.*—Passing now from these questions of flexure and torsion, we consider some results that can be deduced from the general equations of equilibrium of an elastic solid body.

The form of the general expression for the potential energy (ELASTICITY, *Ency. Brit.* vol. vii. p. 823) stored up in the strained body leads, by a general property of quadratic functions, to a reciprocal theorem relating to the effects produced in the body by two different systems of forces, viz.: The whole work done by the forces of the first system acting over the displacements produced by the forces of the second system is equal to the whole work done by the forces of the second system acting over the displacements produced by the forces of the first system. By a suitable choice of the second system of forces the average values of the component stresses and strains produced by given forces, considered as constituting the first system, can be obtained, even when the distribution of the stress and strain cannot be determined.

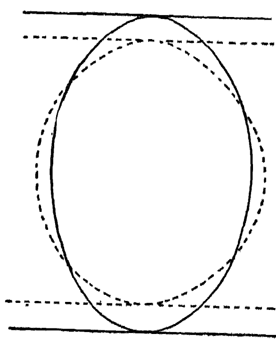

Fig. 18.

Taking for example the problem presented by an isotropic body of any form[1] pressed between two parallel planes distant $l$ apart (Fig. 18), and denoting the resultant pressure by $p$, the diminution of volume $-\delta v$ is given by the equation

$$-\delta v=lp/3k,$$

where $k$ is the modulus of compression, equal to $\frac{1}{3}E/(1-2\sigma)$. Again, taking the problem of the changes produced in a heavy body by different ways of supporting it;

[1] The line joining the points of contact must be normal to the planes.

when the body is suspended from one or more points in a horizontal plane its volume is increased by

$$\delta v = \mathrm{W}h/3k,$$

where W is the weight of the body, and $h$ the depth of its centre of gravity below the plane; when the body is supported by upward vertical pressures at one or more points in a horizontal plane the volume is diminished by

$$-\delta v = \mathrm{W}h'/3k,$$

where $h'$ is the height of the centre of gravity above the plane; if the body is a cylinder, of length $l$ and section A, standing with its base on a smooth horizontal plane, its length is shortened by an amount

$$-\delta l = \mathrm{W}l/2\mathrm{EA};$$

if the same cylinder lies on the plane with its generators horizontal, its length is increased by an amount

$$\delta l = \sigma \mathrm{W}h'/\mathrm{EA}.$$

21. In recent years important results have been found by considering the effects produced in an elastic solid by forces applied at isolated points.

Taking the case of a single force F applied at a point in the interior, it can be shown that the stress at a distance $r$ from the point consists of

(1) a radial pressure of amount

$$\frac{2-\sigma}{1-\sigma}\frac{\mathrm{F}}{4\pi}\frac{\cos\theta}{r^2},$$

(2) tension in all directions at right angles to the radius of amount

$$\frac{1-2\sigma}{2(1-\sigma)}\frac{\mathrm{F}}{4\pi}\frac{\cos\theta}{r^2},$$

(3) shearing stress acting along the radius $dr$ on the surface of the cone $\theta=$const. and acting along the meridian $d\theta$ on the surface of the sphere $r=$const. of amount

$$\frac{1-2\sigma}{2(1-\sigma)}\frac{\mathrm{F}}{4\pi}\frac{\sin\theta}{r^2},$$

where $\theta$ is the angle between the radius vector $r$ and the line of action of F. The line marked T in Fig. 19 shows the direction of this shearing stress on the spherical surface.

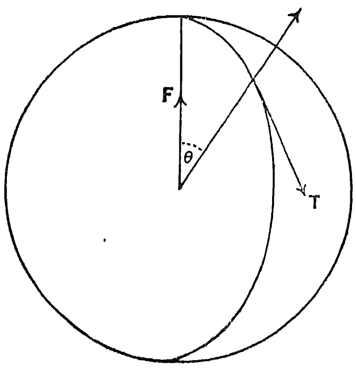

Fig. 19.

Thus the principal stresses are in and perpendicular to the meridian plane, and the direction of one of those in the meridian plane is inclined to the radius vector $r$ at an angle

$$\tfrac{1}{2}\tan^{-1}\left(\frac{2-4\sigma}{5-4\sigma}\tan\theta\right).$$

The corresponding displacement at any point is compounded of a radial displacement of amount

$$\frac{1+\sigma}{2(1-\sigma)}\frac{\mathrm{F}}{4\pi\mathrm{E}}\frac{\cos\theta}{r}$$

and a displacement parallel to the line of action of F of amount

$$\frac{(3-4\sigma)(1+\sigma)}{2(1-\sigma)}\frac{\mathrm{F}}{4\pi\mathrm{E}}\frac{1}{r}.$$

The effects of forces applied at different points and in different directions can be obtained by summation, and the effect of continuously distributed forces can be obtained by integration.

22. The stress system considered in the last section is equivalent, on the plane through the origin at right angles to the line of action of F, to a pressure of magnitude $\frac{1}{2}$F at the origin and a radial shearing stress of amount $\frac{1-2\sigma}{2(1-\sigma)}\frac{\mathrm{F}}{4\pi r^2}$, and, by the application of this system of tractions to a solid bounded by a plane, the displacement just described would be produced. There is also another (Fig. 20) stress system for a solid so bounded which is equivalent, on the same plane, to a pressure at the origin, and a radial shearing stress proportional to $1/r^2$, but these are in the ratio $2\pi : r^{-2}$, instead of being in the ratio $4\pi(1-\sigma) : (1-2\sigma)r^{-2}$.

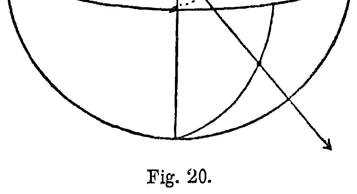

Fig. 20.

The second stress system consists of

(1) radial pressure $\mathrm{F}'r^{-2}$,

(2) tension in the meridian plane across the radius vector of amount

$$\mathrm{F}'r^{-2}\cos\theta/(1+\cos\theta),$$

(3) tension across the meridian plane of amount

$$\mathrm{F}'r^{-2}/(1+\cos\theta),$$

(4) shearing stress as in the last section of amount

$$\mathrm{F}'r^{-2}\sin\theta/(1+\cos\theta),$$

and the stress across the plane boundary consists of a pressure of magnitude $2\pi\mathrm{F}'$ and a radial shearing stress of amount $\mathrm{F}'r^{-2}$. If then we superpose the component stresses of the last section multiplied by $4(1-\sigma)\mathrm{W}/\mathrm{F}$, and the component stresses here written down multiplied by $-(1-2\sigma)\mathrm{W}/2\pi\mathrm{F}'$, the stress on the plane boundary will reduce to a single pressure W at the origin. We shall thus obtain the stress system at any point due to such a force applied at one point of the boundary.

In the stress system thus arrived at the stress across any plane parallel to the boundary is directed away from the place where W is supported, and its amount is $3\mathrm{W}\cos^2\theta/2\pi r^2$. The corresponding displacement consists of

(1) a horizontal displacement radially outwards from the vertical through the origin of amount

$$\frac{\mathrm{W}(1+\sigma)\sin\theta}{2\pi\mathrm{E}r}\left(\cos\theta-\frac{1-2\sigma}{1+\cos\theta}\right),$$

(2) a vertical displacement downwards of amount

$$\frac{\mathrm{W}(1+\sigma)}{2\pi\mathrm{E}r}\{2(1-\sigma)+\cos^2\theta\}.$$

The effects produced by a system of loads on a solid bounded by a plane can be deduced.

23. The results stated in the last section have been applied to give an account of the nature of the actions concerned in the impact of two solid bodies. The dissipation of energy involved in the impact is neglected, and the pressure between the bodies at any instant during the impact is equal to the rate of destruction of momentum of either along the normal to the plane of contact drawn towards the interior of the other. It has been shown that in general the bodies come into contact over a small area bounded by an ellipse, and remain in contact for a time which varies inversely as the fifth root of the initial relative velocity.

For equal spheres of the same material, with $\sigma=\frac{1}{4}$, impinging directly with relative velocity $v$, the patches that come into contact are circles of radius

$$\left(\frac{75\pi}{256}\right)^{\frac{1}{5}}\left(\frac{v}{\mathrm{V}}\right)^{\frac{2}{5}}r,$$

where $r$ is the radius of either, and V is the velocity of longitudinal waves in a thin bar of the material. The duration of the impact is approximately

$$(2{\cdot}9432)\left(\frac{375\pi^2}{128}\right)^{1/5}\frac{r}{v^{1/5}\mathrm{V}^{4/5}}.$$

For two steel spheres of the size of the earth impinging with a velocity of 10 mm. per second the duration of the impact would be about twenty-seven hours. The fact that the duration of impact is, for moderate velocities, a considerable multiple of the time taken by a wave of compression to travel through either of two impinging bodies has been ascertained experimentally,[1] and constitutes the reason for the adequacy of the statical theory here described.

24. *Spheres and Cylinders.*—Simple results can be found for spherical and cylindrical bodies strained by radial forces.

For a sphere of radius $a$, and of homogeneous isotropic material of density $\rho$, strained by the mutual gravitation of its parts, the stress at a distance $r$ from the centre consists of

(1) uniform hydrostatic pressure of amount $\frac{1}{10}g\rho a(3-\sigma)/(1-\sigma)$,

(2) radial tension of amount $\frac{1}{10}g\rho(r^2/a)(3-\sigma)/(1-\sigma)$,

[1] Cf. Auerbach in Winkelmann's *Handbuch der Physik*, i. 303. Breslau, 1891.

(3) uniform tension at right angles to the radius vector of amount

$$\tfrac{1}{10}g\rho(r^2/a)(1+3\sigma)/(1-\sigma),$$

where $g$ is the value of gravity at the surface. The corresponding strains consist of

(1) uniform contraction of all lines of the body of amount

$$\tfrac{1}{30}k^{-1}g\rho a(3-\sigma)/(1-\sigma),$$

(2) radial extension of amount $\tfrac{1}{10}k^{-1}g\rho(r^2/a)(1+\sigma)/(1-\sigma)$,

(3) extension in any direction at right angles to the radius vector of amount

$$\tfrac{1}{30}k^{-1}g\rho(r^2/a)(1+\sigma)/(1-\sigma),$$

where $k$ is the modulus of compression. The volume is diminished by the fraction $g\rho a/5k$ of itself. The parts of the radii vectores within the sphere $r=a\{(3-\sigma)/(3+3\sigma)\}^{1/2}$ are contracted, and the parts without this sphere are extended. The application of the above results to the state of the interior of the earth is restricted by the circumstance that, unless the modulus of compression is much greater than that of any known material, the stresses and strains expressed above would, in a sphere of the size of the earth, greatly exceed the elastic limits.

25. In a spherical shell of homogeneous isotropic material, of internal radius $r_1$ and external radius $r_0$, subjected to pressure $p_0$ on the outer surface, and $p_1$ on the inner surface, the stress at any point distant $r$ from the centre consists of

(1) uniform tension in all directions of amount $\dfrac{p_1r_1^3-p_0r_0^3}{r_0^3-r_1^3}$,

(2) radial pressure of amount $\dfrac{p_1-p_0}{r_0^3-r_1^3}\dfrac{r_0^3r_1^3}{r^3}$,

(3) tension in all directions at right angles to the radius vector of amount

$$\frac{1}{2}\frac{p_1-p_0}{r_0^3-r_1^3}\frac{r_0^3r_1^3}{r^3}.$$

The corresponding strains consist of

(1) uniform extension of all lines of the body of amount

$$\frac{1}{3k}\frac{p_1r_1^3-p_0r_0^3}{r_0^3-r_1^3},$$

(2) radial contraction of amount $\dfrac{1}{2\mu}\dfrac{p_1-p_0}{r_0^3-r_1^3}\dfrac{r_0^3r_1^3}{r^3}$,

(3) extension in all directions at right angles to the radius vector of amount

$$\frac{1}{4\mu}\frac{p_1-p_0}{r_0^3-r_1^3}\frac{r_0^3r_1^3}{r^3},$$

where $\mu$ is the modulus of rigidity of the material, $=\frac{1}{2}\mathrm{E}/(1+\sigma)$. The volume included between the two surfaces of the body is increased by the fraction $\dfrac{p_1r_1^3-p_0r_0^3}{k(r_0^3-r_1^3)}$ of itself, and the volume within the inner surface is increased by the fraction

$$\frac{3(p_1-p_0)}{4\mu}\frac{r_0^3}{r_0^3-r_1^3}+\frac{p_1r_1^3-p_0r_0^3}{k(r_0^3-r_1^3)}$$

of itself. For a shell subject only to internal pressure $p$ the greatest extension is the extension at right angles to the radius at the inner surface, and its amount is

$$\frac{pr_1^3}{r_0^3-r_1^3}\left(\frac{1}{3k}+\frac{1}{4\mu}\frac{r_0^3}{r_1^3}\right);$$

the greatest tension is the transverse tension at the inner surface, and its amount is $p(\frac{1}{2}r_0^3+r_1^3)/(r_0^3-r_1^3)$.

26. In the problem of a cylindrical shell under pressure a complication may arise from the effects of the ends; but when the ends are free from stress the solution is very simple. With notation similar to that in § 25 it can be shown that the stress at a distance $r$ from the axis consists of

(1) uniform tension in all directions at right angles to the axis of amount

$$\frac{p_1r_1^2-p_0r_0^2}{r_0^2-r_1^2},$$

(2) radial pressure of amount $\dfrac{p_1-p_0}{r_0^2-r_1^2}\dfrac{r_0^2r_1^2}{r^2}$,

(3) hoop tension numerically equal to this radial pressure.

The corresponding strains consist of

(1) uniform extension of all lines of the material at right angles to the axis of amount

$$\frac{1-\sigma}{\mathrm{E}}\frac{p_1r_1^2-p_0r_0^2}{r_0^2-r_1^2},$$

(2) radial contraction of amount

$$\frac{1+\sigma}{\mathrm{E}}\frac{p_1-p_0}{r_0^2-r_1^2}\frac{r_0^2r_1^2}{r^2},$$

(3) extension along the circular filaments numerically equal to this radial contraction,

(4) uniform contraction of the longitudinal filaments of amount

$$\frac{2\sigma}{\mathrm{E}}\frac{p_1r_1^2-p_0r_0^2}{r_0^2-r_1^2}.$$

For a shell subject only to internal pressure $p$ the greatest extension is the circumferential extension at the inner surface, and its amount is

$$\frac{p}{\mathrm{E}}\left(\frac{r_0^2+r_1^2}{r_0^2-r_1^2}+\sigma\right);$$

the greatest tension is the hoop tension at the inner surface, and its amount is $p(r_0^2+r_1^2)/(r_0^2-r_1^2)$.

27. The results just obtained have been applied to gun construction; we may consider that one cylinder is heated so as to slip over another upon which it shrinks by cooling, so that the two form a single body in a condition of initial stress.

We take P as the measure of the pressure between the two, and $p$ for the pressure within the inner cylinder by which the system is afterwards strained, and denote by $r'$ the radius of the common surface. To obtain the stress at any point we superpose the system consisting of radial pressure $p\dfrac{r_1^2}{r^2}\dfrac{r_0^2-r^2}{r_0^2-r_1^2}$ and hoop tension $p\dfrac{r_1^2}{r^2}\dfrac{r_0^2+r^2}{r_0^2-r_1^2}$ upon a system which, for the outer cylinder, consists of radial pressure $\mathrm{P}\dfrac{r'^2}{r^2}\dfrac{r_0^2-r^2}{r_0^2-r'^2}$ and hoop tension $\mathrm{P}\dfrac{r'^2}{r^2}\dfrac{r_0^2+r^2}{r_0^2-r'^2}$ and, for the inner cylinder consists of radial pressure $\mathrm{P}\dfrac{r'^2}{r^2}\dfrac{r^2-r_1^2}{r'^2-r_1^2}$ and hoop tension $-\mathrm{P}\dfrac{r'^2}{r^2}\dfrac{r^2+r_1^2}{r'^2-r_1^2}$. The hoop tension at the inner surface is less than it would be for a tube of equal thickness without initial stress in the ratio

$$1-\frac{\mathrm{P}}{p}\frac{2r'^2}{r_0^2+r_1^2}\frac{r_0^2-r_1^2}{r'^2-r_1^2}:1.$$

This shows how the strength of the tube is increased by the initial stress.

28. The problem of determining the distribution of stress and strain in a circular cylinder, rotating about its axis, has not yet been completely solved, but solutions have been obtained which are sufficiently exact for the two special cases of a thin disk and a long shaft.

Suppose that a circular disk of radius $a$ and thickness $2l$, and of density $\rho$, rotates about its axis with angular velocity $\omega$, and consider the following systems of superposed stresses at any point distant $r$ from the axis and $z$ from the middle plane:

(1) uniform tension in all directions at right angles to the axis of amount $\frac{1}{8}\omega^2\rho a^2(3+\sigma)$,

(2) radial pressure of amount $\frac{1}{8}\omega^2\rho r^2(3+\sigma)$,

(3) pressure along the circular filaments of amount $\frac{1}{8}\omega^2\rho r^2(1+3\sigma)$,

(4) uniform tension in all directions at right angles to the axis of amount $\frac{1}{6}\omega^2\rho(l^2-3z^2)\sigma(1+\sigma)/(1-\sigma)$.

The corresponding strains may be expressed as

(1) uniform extension of all filaments at right angles to the axis of amount

$$\frac{1-\sigma}{\mathrm{E}}\tfrac{1}{8}\omega^2\rho a^2(3+\sigma),$$

(2) radial contraction of amount

$$\frac{1-\sigma^2}{\mathrm{E}}\tfrac{3}{8}\omega^2\rho r^2,$$

(3) contraction along the circular filaments of amount

$$\frac{1-\sigma^2}{\mathrm{E}}\tfrac{1}{8}\omega^2\rho r^2,$$

(4) extension of all filaments at right angles to the axis of amount

$$\frac{1}{\mathrm{E}}\tfrac{1}{6}\omega^2\rho(l^2-3z^2)\sigma(1+\sigma),$$

(5) contraction of the filaments normal to the plane of the disk of amount

$$\frac{2\sigma}{\mathrm{E}}\tfrac{1}{8}\omega^2\rho a^2(3+\sigma)-\frac{\sigma}{\mathrm{E}}\tfrac{1}{2}\omega^2\rho r^2(1+\sigma)+\frac{2\sigma}{\mathrm{E}}\tfrac{1}{6}\omega^2\rho(l^2-3z^2)\sigma\frac{(1+\sigma)}{1-\sigma}.$$

The greatest extension is the circumferential extension near the centre, and its amount is

$$\frac{(3+\sigma)(1-\sigma)}{8\mathrm{E}}\omega^2\rho a^2+\frac{\sigma(1+\sigma)}{6\mathrm{E}}\omega^2\rho l^2.$$

The longitudinal contraction is required to make the plane faces

of the disk free from pressure, and the terms in $l$ and $z$ enable us to avoid shearing stress on any cylindrical surface. The system of stresses and strains thus expressed satisfies all the conditions, except that there is a small radial tension on the bounding surface of amount per unit area $\frac{1}{6}\omega^2\rho(l^2-3z^2)\sigma(1+\sigma)/(1-\sigma)$. The resultant of these stresses on any part of the edge of the disk vanishes, and the stress in question is very small in comparison with the other stresses involved when the disk is thin; we may conclude that for a thin disk the expressions given represent the actual condition at all points which are not very close to the edge (cf. § 9). The effect of the longitudinal contraction is that the plane faces become slightly concave (Fig. 21).

In problems of the kind just considered, where the stress consists simply of a radial tension P and a circumferential tension Q, which are functions of $r$ and $z$, the stress components, besides satisfying the equations of equilibrium, are also subject to two conditions of compatibility which can be expressed in the forms

$$(1+\sigma)\frac{\mathrm{P}-\mathrm{Q}}{r}=\frac{\partial \mathrm{Q}}{\partial r}-\sigma\frac{\partial \mathrm{P}}{\partial r},$$

$$r\frac{\partial^2}{\partial z^2}(\mathrm{Q}-\sigma\mathrm{P})=\sigma\frac{\partial}{\partial r}(\mathrm{P}+\mathrm{Q})$$

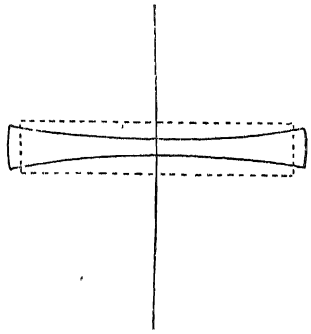

Fig. 21.

29. The corresponding solution for a disk with a circular axle-hole (radius $b$) will be obtained from that given in the last section by superposing the following system of additional stresses:

(1) radial tension of amount $\frac{1}{8}\omega^2\rho b^2(1-a^2/r^2)(3+\sigma)$,
(2) tension along the circular filaments of amount

$$\tfrac{1}{8}\omega^2\rho b^2(1+a^2/r^2)(3+\sigma);$$

and the corresponding additional strains are
(1) radial contraction of amount

$$\frac{3+\sigma}{8\mathrm{E}}\left\{(1+\sigma)\frac{a^2}{r^2}-(1-\sigma)\right\}\omega^2\rho b^2.$$

(2) extension along the circular filaments of amount

$$\frac{3+\sigma}{8\mathrm{E}}\left\{(1+\sigma)\frac{a^2}{r^2}+(1-\sigma)\right\}\omega^2\rho b^2,$$

(3) contraction of the filaments parallel to the axis of amount

$$\frac{\sigma(3+\sigma)}{4\mathrm{E}}\omega^2\rho b^2.$$

Again, the greatest extension is the circumferential extension at the inner surface, and, when the hole is very small, its amount is nearly double what it would be for a complete disk.

30. In the problem of the rotating shaft we have the following stress-system:
(1) radial tension of amount $\frac{1}{8}\omega^2\rho(a^2-r^2)(3-2\sigma)/(1-\sigma)$,
(2) circumferential tension of amount

$$\tfrac{1}{8}\omega^2\rho\{a^2(3-2\sigma)/(1-\sigma)-r^2(1+2\sigma)/(1-\sigma)\},$$

(3) longitudinal tension of amount $\frac{1}{4}\omega^2\rho(a^2-2r^2)\sigma/(1-\sigma)$.

The resultant longitudinal tension at any normal section vanishes, and the radial tension vanishes at the bounding surface; and thus the expressions here given may be taken to represent the actual condition at all points which are not very close to the ends of the shaft. The contraction of the longitudinal filaments is uniform and equal to $\frac{1}{2}\omega^2\rho a^2\sigma/\mathrm{E}$. The greatest extension in the rotating shaft is the circumferential extension close to the axis, and its amount is $\frac{1}{8}\omega^2\rho a^2(3-5\sigma)/\mathrm{E}(1-\sigma)$.

The value of any theory of the strength of long rotating shafts founded on these formulæ is diminished by the circumstance that at sufficiently high speeds the shaft may tend to take up a curved form, the straight form being unstable. The shaft is then said to *whirl*. This occurs when the period of rotation of the shaft is very nearly coincident with one of its periods of lateral vibration. (See Greenhill, *Proc. Inst. Mech. Engineers*, April 1883.) The lowest speed at which whirling can take place in a shaft of length $l$, freely supported at its ends, is given by the formula

$$\omega^2\rho=\tfrac{1}{4}\mathrm{E}a^2(\pi/l)^4.$$

As in § 14, this formula should not be applied unless the length of the shaft is a considerable multiple of its diameter. It implies that whirling is to be expected whenever $\omega$ approaches this critical value.

31. *Thin Plate under Pressure.*—The theory of the deformation of plates, whether plane or curved, is very intricate, partly because of the complexity of the kinematical relations involved. We shall here indicate the nature of the effects produced in a thin plane plate, of isotropic material, which is slightly bent by pressure. This theory should have an application to the stress produced in a ship's plates. In the problem of the cylinder (§ 26) the most important stress is the circumferential tension, counteracting the tendency of the circular filaments to expand under the pressure; but in the problem of a plane plate some of the filaments parallel to the plane of the plate are extended and others are contracted, so that the tensions and pressures along them give rise to resultant couples but not to resultant forces. Whatever forces are applied to bend the plate, these couples are always expressible in terms of the principal curvatures produced in the surface which, before strain, was the middle plane of the plate. The simplest case is that of a rectangular plate, bent by a distribution of couples applied to its edges, so that the middle surface becomes a cylinder of large radius R; the requisite couple per unit of length of the straight edges is of amount C/R, where C is a certain constant; and the requisite couple per unit of length of the circular edges is of amount $\mathrm{C}\sigma/\mathrm{R}$, the latter being required to resist the tendency to anticlastic curvature (cf. § 1). If normal sections of the plate are supposed drawn through the generators and circular sections of the cylinder, the action of the neighbouring portions on any portion so bounded involves flexural couples of the above amounts. When the plate is bent in any manner, the curvature produced at each section of the middle surface may be regarded as arising from the superposition of two cylindrical curvatures; and the flexural couples across normal sections through the lines of curvature, estimated per unit of length of those lines, are $\mathrm{C}(1/\mathrm{R}_1+\sigma/\mathrm{R}_2)$ and $\mathrm{C}(1/\mathrm{R}_2+\sigma/\mathrm{R}_1)$, where $\mathrm{R}_1$ and $\mathrm{R}_2$ are the principal radii of curvature. The value of C for a plate of small thickness $2h$ is $\frac{2}{3}\mathrm{E}h^3/(1-\sigma^2)$. Exactly as in the problem of the beam (§§ 2, 10), the action between neighbouring portions of the plate generally involves shearing stresses across normal sections as well as flexural couples; and the resultants of these stresses are determined by the conditions that, with the flexural couples, they balance the forces applied to bend the plate.

32. To express this theory analytically, let the middle plane of the plate in the unstrained position be taken as the plane of $(x, y)$, and let normal sections at right angles to the axes of $x$ and $y$ be drawn through any point. After strain let $w$ be the displacement of this point in the direction perpendicular to the plane, marked $p$ in Fig. 22. If the axes of $x$ and $y$ were parallel to the lines of

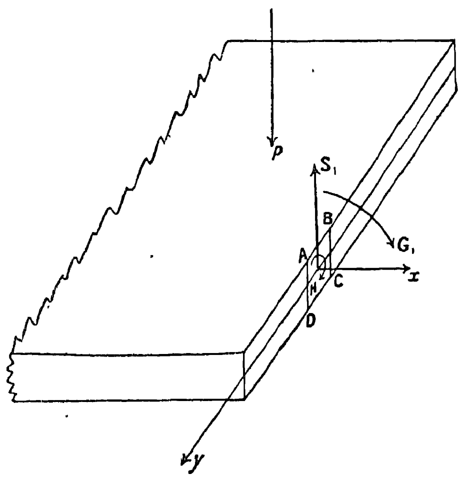

Fig. 22.

curvature at the point, the flexural couple acting across the section normal to $x$ (or $y$) would have the axis of $y$ (or $x$) for its axis; but when the lines of curvature are inclined to the axes of co-ordinates,

the flexural couple across a section normal to either axis has a component about that axis as well as a component about the perpendicular axis. Considering an element ABCD of the section at right angles to the axis of $x$, contained between two lines near together and perpendicular to the middle plane, the action of the portion of the plate to the right upon the portion to the left, across the element, gives rise to a couple about the middle line ($y$) of amount, estimated per unit of length of that line, equal to $C\left(\frac{\partial^2 w}{\partial x^2}+\sigma\frac{\partial^2 w}{\partial y^2}\right), =G_1$, say, and to a couple, similarly estimated, about the normal ($x$) of amount $-C(1-\sigma)\frac{\partial^2 w}{\partial x\partial y}, =H$, say. The corresponding couples on an element of a section at right angles to the axis of $y$, estimated per unit of length of the axis of $x$, are of amounts $-C\left(\frac{\partial^2 w}{\partial y^2}+\sigma\frac{\partial^2 w}{\partial x^2}\right), =G_2$ say, and $-H$. The resultant $S_1$ of the shearing stresses on the element ABCD, estimated as before, is given by the equation $S_1=\frac{\partial G_1}{\partial x}-\frac{\partial H}{\partial y}$ (cf. § 10), and the corresponding resultant $S_2$ for an element perpendicular to the axis of $y$ is given by the equation $S_2=-\frac{\partial H}{\partial x}-\frac{\partial G_2}{\partial y}$. If the plate is bent by a pressure $p$ per unit of area, the equation of equilibrium is $\frac{\partial S_1}{\partial x}+\frac{\partial S_2}{\partial y}=p$, or, in terms of $w$,

$$\frac{\partial^4 w}{\partial x^4}+\frac{\partial^4 w}{\partial y^4}+2\frac{\partial^4 w}{\partial x^2\partial y^2}=\frac{p}{C}.$$

This equation, together with the special conditions at the rim, suffices for the determination of $w$, and then all the quantities here introduced are determined. Further, the most important of the stress-components are those which act across elements of normal sections: the tension in direction $x$, at a distance $z$ from the middle plane measured in the direction of $p$, is of amount $-\frac{3Cz}{2h^3}\left(\frac{\partial^2 w}{\partial x^2}+\sigma\frac{\partial^2 w}{\partial y^2}\right)$, and there is a corresponding tension in direction $y$; the shearing stress parallel to $y$ on planes $x=\text{const.}$, and parallel to $x$ on planes $y=\text{const.}$, is of amount $\frac{3C(1-\sigma)z}{2h^3}\frac{\partial^2 w}{\partial x\partial y}$; these tensions and shearing stresses are equivalent to two principal tensions, in the directions of the lines of curvature of the surface into which the middle plane is bent, and they give rise to the flexural couples.

33. In the special example of a circular plate, of radius $a$, supported at the rim, and held bent by a uniform pressure $p$, the value of $w$ at a point distant $r$ from the axis is

$$\frac{1}{64}\frac{p}{C}(a^2-r^2)\left(\frac{5+\sigma}{1+\sigma}a^2-r^2\right),$$

and the most important of the stress components is the radial tension, of which the amount at any point is $\frac{3}{32}(3+\sigma)pz(a^2-r^2)/h^3$; the maximum radial tension is about $\frac{1}{3}(a/h)^2p$, and, when the thickness is small compared with the diameter, this is a large multiple of $p$.

**Elba,** an island of Italy, belonging to the province of Leghorn, 4 miles from the nearest point of the mainland (Piombino), and 35 miles south from Leghorn. Iron is not only mined, but since 1900 smelted, in Elba. Iron ore, wine, and salt are exported to the average (1891–98) value of £197,250 (£244,000 in 1899). The shipping which cleared from the various ports increased from 2692 vessels of 209,500 tons in 1891 to 3004 of 568,930 tons in 1899. There is an institute of viticulture. On this and the neighbouring island of Pianosa there are convict prisons, in which from 3000 to 4000 convicts are lodged. The principal towns are Portoferrajo (population, 3737 in 1881), Marciana (5444), Portolungone (4172), and Rio Marina (2964). Population of the island, about 27,000.

**Elbe** (the *Albis* of the Romans), one of the most important rivers of Central Europe. It rises in Bohemia, in the upper gathering-grounds of the Riesengebirge, its chief feeders being the Weisswasser, which originates near the kingly Schneekoppe, at an altitude of about 4600 feet, and the Elbseifen, which is formed in the same neighbourhood, but at a little lower elevation. After plunging down the 140 feet of the Elbfall, the latter stream unites with the steep torrential Weisswasser at Mädelstegbaude, at an altitude of 2230 feet, and thereafter the united stream of the Elbe pursues a southerly course, emerging from the mountain glens at Hohenelbe (1495 feet), and continuing on at a soberer pace to Pardubitz, where it turns sharply to the west, and at Kolin (730 feet), some 27 miles farther on, bends gradually towards the north-west. A little above Brandeis it picks up the Iser, which, like itself, comes down from the Riesengebirge, and at Melnik it has its stream more than doubled in volume by the Moldau, a river which winds northwards through the heart of Bohemia in a sinuous, trough-like channel carved through the plateaux. Some miles lower down, at Leitmeritz (433 feet), the waters of the Elbe are tinted by the reddish Eger, a stream which drains the southern slopes of the Erzgebirge. Thus augumented, and swollen into a stream 140 yards wide, the Elbe carves a path through the basaltic mass of the Mittelgebirge, churning its way through a deep, narrow rocky gorge. Then the river winds through the fantastically sculptured sandstone mountains of the "Saxon Switzerland," washing successively the feet of the lofty Lilienstein (932 feet above the Elbe), the scene of one of Frederick the Great's military exploits in the Seven Years' War, Königstein (797 feet above the Elbe), where in times of war Saxony has more than once stored her national purse for security, and the pinnacled rocky wall of the Bastei, towering 650 feet above the surface of the stream. Shortly after crossing the Bohemian-Saxon frontier, and whilst still struggling through the sandstone defiles, the stream assumes a north-westerly direction, which on the whole it preserves right away to the North Sea. At Pirna the Elbe leaves behind it the stress and turmoil of the Saxon Switzerland, rolls through Dresden, with its noble river terraces, and finally, beyond Meissen, enters on its long journey across the North German plain, touching Torgau, Wittenberg, Magdeburg, Wittenberge, Hamburg, Harburg, and Altona on the way, and gathering into itself the waters of the Mulde and Saale from the left, and those of the Schwarze Elster, Havel, and Elde from the right. Eight miles above Hamburg the stream divides into the Norder (or Hamburg) Elbe and the Süder (or Harburg) Elbe, which are linked together by several cross-channels, and embrace in their arms the large island of Wilhelmsburg and some smaller ones. But by the time the river reaches Blankenese, 7 miles below Hamburg, all these anastomosing branches have been reunited, and the Elbe, with a noble width of 4 to 9 miles between bank and bank, travels on between the green marshes of Holstein and Hanover until it becomes merged in the North Sea off Cuxhaven. From Dresden to the sea the river has a total fall of only 123 feet, although the distance is about 430 miles. For the 75 miles between Hamburg and the sea the fall is only $3\frac{1}{4}$ feet. One consequence of this is that the bed of the river

just below Hamburg is obstructed by a bar, and still lower down is choked with sandbanks, so that navigation is confined to a relatively narrow channel down the middle of the stream. But Hamburg has been unremitting in her efforts to maintain a sufficient fairway, and now vessels drawing 26 feet are able to proceed right up to her wharves, the depth of water on the bar having been increased from 14 feet in 1830 to 24½ feet in 1899. The tide advances as far as Geesthacht, a little more than 100 miles from the sea. The river is navigable as far as Melnik, that is, the confluence of the Moldau, a distance of 525 miles, of which 67 are in Bohemia. Its total length is 725 miles, of which 190 miles are in Bohemia, 77 miles in the kingdom of Saxony, and 350 miles in Prussia, the remaining 108 miles being in Hamburg and other states of Germany. The area of the drainage basin is estimated at 56,000 square miles.

Since 1842, but more especially since 1871, improvements have been made in the navigability of the Elbe by all the states which border upon its banks. As a result of these labours, there is now in the Bohemian portion of the river a minimum depth of 2 feet 8 inches, whilst from the Bohemian frontier down to Magdeburg the minimum depth is 3 feet, and from Magdeburg to Hamburg, 3 feet 10 inches. In 1896 and 1897 Prussia and Hamburg signed covenants whereby two channels are to be kept open to a depth of 9¾ feet, a width of 656 feet, and a length of 550 yards between Bunthaus and Ortkathen, just above the bifurcation of the Norder Elbe and the Suder Elbe. In 1869 the maximum burden of the vessels which were able to ply on the upper Elbe was 250 tons; but in 1899 it was increased to 800 tons. The large towns through which the river flows have vied with one another in building harbours, providing shipping accommodation, and furnishing other facilities for the efficient navigation of the Elbe. In this respect the greatest efforts have naturally been made by Hamburg (*q.v.*); but Magdeburg, Dresden, Meissen, Riesa, Tetschen, Aussig, and other places have all done their relative shares, Magdeburg, for instance, providing a commercial harbour and a winter harbour. In spite, however, of all that has been done, the Elbe remains subject to serious inundations at periodic intervals. Some of the worst floods which have been occasioned by this river have occurred in the years 1774, 1799, 1815, 1830, 1845, 1862, and 1890.

The growth of the traffic up and down the Elbe during the last quarter of the 19th century will be illustrated by the subjoined table, which shows the number of vessels, with their tonnage, which passed the river stations of Schandau (near the Saxon-Bohemian frontier), the Plauer Schleuse (some 20 miles below Magdeburg), and Hamburg-Entenwärder—(i.) the annual average for the years 1872–75, and (ii.) for the year 1899.

| | | Up-stream. | | Down-stream. | |
|---|---|---|---|---|---|
| | | Vessels. | Tons. | Vessels. | Tons. |
| Schandau | 1872–75 | 4,336 | 30,600 | 3,152 | 429,200 |
| | 1899 | 8,489 | 3,045,600 | 7,795 | 4,509,500 |
| Plauer Schleuse | 1872–75 | 2,313 | 108,600 | 2,099 | 148,000 |
| | 1899 | 5,149 | 1,223,100 | 5,269 | 1,739,500 |
| Hamburg-Entenwärder | 1872–75 | 5,053 | 438,700 | 4,725 | 256,400 |
| | 1899 | 24,480 | 6,607,000 | 26,706 | 6,174,600 |

In addition to this, timber rafts with an annual average of 154,500 tons of timber passed downwards through Schandau, and 34,400 tons through Hamburg, in the years 1872–75; the corresponding figures for 1899 being 284,100 tons through Schandau and 23,600 tons through Hamburg. The value of the goods forwarded from Hamburg to the interior of Germany up the Elbe in the year 1899 was estimated at over 34½ millions sterling, equivalent to about 20 per cent. of the entire exports from Hamburg. This vast amount of traffic is directed principally to Berlin, by means of the Havel-Spree system of canals, to the Thuringian states and the Prussian province of Saxony, to the kingdom of Saxony and Bohemia, and to the various riverine states and provinces of the lower and middle Elbe. The passenger traffic, which is in the hands of the Sächsisch-Böhmische Dampfschiffahrtsgesellschaft, is limited to Bohemia and Saxony, steamers plying up and down the stream from Dresden to Melnik, occasionally continuing the journey up the Moldau to Prague, and down the river as far as Riesa, near the northern frontier of Saxony. The carrying trade and the towing of barges are conducted by several large navigation companies.

In 1877–79, and again in 1888–95, some 100 miles of canal were dug, 5 to 6½ feet deep and of various widths, for the purpose of connecting the Elbe, through the Havel and the Spree, with the system of the Oder. The most noteworthy of these connexions are the Elbe Canal (14¼ miles long), the Reek Canal (9½ miles), the Rüdesdorfer Gewässer (11½ miles), the Rheinsberger Canal (11¼ miles), and the Sacrow-Paretzer Canal (10 miles), besides which the Spree has been canalized for a distance of 28 miles, and the Elbe for a distance of 70 miles. Since 1896 great improvements have been made in the Moldau and the Bohemian Elbe, with the view of facilitating communication between Prague and the middle of Bohemia generally on the one hand, and the middle and lower reaches of the Elbe on the other. In the year named a special commission was appointed for the regulation of the Moldau and Elbe between Prague and Aussig, at a cost estimated at about £1,000,000, of which sum two-thirds were to be borne by the Austrian empire and one-third by the kingdom of Bohemia. The regulation is being effected by the construction of locks and movable dams, the latter so designed that in times of flood or frost they can be dropped flat on the bottom of the river. When all these works are finished, the two rivers will have a minimum depth over the distances indicated of 6¾ feet, and will be able to accommodate barges of 700 to 800 tons when fully laden. In 1901 the Austrian Government laid before the Reichsrath a canal Bill, with proposals (1) for constructing a canal from the Danube (probably near Linz) to the Moldau near Budweis, a distance of 80 miles, and for regulating the Moldau from Budweis down to Prague; (2) for constructing a canal from the Danube to the Oder; (3) for constructing a canal between this last, starting at Prerau and ending at Pardubitz on the upper Elbe, and for the canalization of the Elbe from Pardubitz to Melnik; and (4) for making a navigable canal to unite the Danube-Oder section with the basin of the Vistula and with the navigable portion of the Dniester. The total cost was estimated at £31,000,000, and the time the works would take at twenty years. In 1900 Lübeck was put into direct communication with the Elbe at Lauenburg by the opening of the Elbe-Trave Canal, 42 miles in length, and constructed at a cost of £1,177,700, of which the state of Lübeck contributed £802,700, and the kingdom of Prussia £375,000. The canal has been made 72 feet wide at the bottom, 105 to 126 feet wide at the top, has a minimum depth of 8½ feet, and is equipped with seven locks, each 262½ feet long and 39¼ feet wide. It is thus able to accommodate vessels up to 800 tons burden; and the passage from Lübeck to Lauenburg occupies 18 to 21 hours. In the first year of its being open (June 1900 to June 1901) a total of 115,000 tons passed through the canal.[1] A gigantic project has also been put forward for providing water communication between the Rhine and the Elbe, and so with the Oder, through the heart of Germany. Some particulars of this scheme, which is known as the Midland Canal, are given in the article CANALS. Another canal has been projected for connecting Kiel with the Elbe by means of a canal trained through the Plön Lakes.

The Elbe is crossed by numerous bridges, as at Königgratz, Pardubitz, Kolin, Leitmeritz, Tetschen, Schandau, Pirna, Dresden, Meissen, Torgau, Wittenberg, Rosslau, Barby, Magdeburg, Rathenow, Wittenberge, Dömitz, Lauenburg, and Hamburg and Harburg. At all these places there are railway bridges, and nearly all, but more especially those in Bohemia, Saxony, and the middle course of the river—these last on the main lines between Berlin and the west and south-west of the empire—possess a greater or less strategic value. At Leitmeritz there is an iron trellis bridge, 600 yards long. Dresden has four bridges, three built in the 19th century, one of them serving also as a railway bridge, and the fourth early in the 18th century; there is a fifth bridge at Loschwitz, about three miles above the city. Meissen has a new railway bridge, in addition to an old road bridge. Magdeburg is one of the most important railway centres in Northern Germany; and the Elbe, besides being bridged—it divides there into three arms—several times for vehicular traffic, is also spanned by two fine railway bridges. At both Hamburg and Harburg, again, there are handsome new railway bridges, the one (1868–73 and 1894) crossing the Northern Elbe, and the other (1900) the Southern Elbe; and the former arm is also crossed by a fine triple-arched bridge (1888) for vehicular traffic.

The river is well stocked with fish, both salt-water and fresh-water species being found in its waters, and several varieties of fresh-water fish in its tributaries. The kinds of greatest economic value are sturgeon, shad, salmon, lampreys, eels, pike, and whiting.

In the days of the old German empire no fewer than thirty-five different tolls were levied between Melnik and Hamburg, to say nothing of the special dues and privileged exactions of various riparian owners and political authorities. After these had been *de facto*, though not *de jure*, in abeyance during the period of the Napoleonic wars, a commission of the various Elbe states met and drew up a scheme for their regulation, and the scheme, embodied

[1] See *Der Bau des Elbe-Trave Canals und seine Vorgeschichte.* Lübeck, 1900.

in the Elbe Navigation Acts, came into force in 1822. By this a definite number of tolls, at fixed rates, was substituted for the often arbitrary tolls which had been exacted previously. Still further relief was afforded in 1844 and in 1850, on the latter occasion by the abolition of all tolls between Melnik and the Saxon frontier. But the number of tolls was only reduced to one, levied at Wittenberge, in 1863, about one year after Hanover was induced to give up the Stade or Brunsbuttel toll in return for a compensation of 2,857,340 thalers. Finally, in 1870, 1,000,000 thalers were paid to Mecklenburg and 85,000 thalers to Anhalt, who thereupon abandoned all claims to levy tolls upon the Elbe shipping, and thus navigation on the river became at last entirely free.

The Elbe cannot rival the Rhine in the picturesqueness of the scenery it travels through, nor in the glamour which its romantic and legendary associations exercise over the imagination.

***History.***

But it possesses much to charm the eye in the deep glens of the Riesengebirge, amid which its sources spring, and in the bizarre rock-carving of the Saxon Switzerland. And it has been indirectly or directly associated with many stirring events in the history of the German peoples. In its lower course, whatever is worthy of record clusters round the historical vicissitudes of Hamburg—its early prominence as a missionary centre (Ansgar) and as a bulwark against Slav and marauding Northman, its commercial prosperity as a leading member of the Hanseatic League, and its sufferings during the Napoleonic wars, especially at the hands of the ruthless Davoût. The bridge over the river at Dessau recalls the hot assaults of that ill-favoured *condottiere* Ernst von Mansfeld in April 1626, and his repulse by the crafty generalship of Wallenstein. But three years later this imperious leader was checked by the heroic resistance of the "Maiden" fortress of Magdeburg; though two years later still she lost her reputation, and suffered unspeakable horrors at the hands of Tilly's lawless and unlicensed *soldatesca*. Mühlberg, just outside the Saxon frontier, is the place where Charles V. asserted his imperial authority over the Protestant elector of Saxony, John Frederick, the Magnanimous or Unfortunate, in 1547. Dresden, Aussig, and Leitmeritz are all reminiscent of the fierce battles of the Hussite wars, and the last-named of the Thirty Years' War. But the chief historical associations of the upper (*i.e.*, the Saxon and Bohemian) Elbe are those which belong to the Seven Years' War and the struggle of the great Frederick of Prussia against the power of Austria and her allies. At Pirna (and Lilienstein) in 1756, he caught the entire Saxon army in his fowler's net, after driving back at Lobositz the Austrian forces which were hastening to their assistance; but only nine months later he lost his reputation for "invincibility" by his crushing defeat at Kolin, where the great highway from Vienna to Dresden crosses the Elbe. Not many miles distant, higher up the stream, another decisive battle was fought between the same national antagonists, but with a contrary result, on the memorable 3rd July 1866.

See M. BUCHHEISTER, "Die Elbe u. der Hafen von Hamburg," in *Mitteil. d. Geog. Gesellsch. in Hamburg* (1899), vol. xv. pp. 131–188; V. KURS, "Die künstlichen Wasserstrassen des deutschen Reichs," in *Geog. Zeitschrift* (1898), pp. 601–617; and (the official) *Der Elbstrom* (1900). (J. T. BE.)

**Elberfeld,** a town of Prussia, in the Rhine province, on the river Wupper, 15 miles by rail east from Dusseldorf. Since 1874 several new and handsome quarters have been built to the south and west of the older part of the town. A new town-hall was erected in 1899–1900. The more recent buildings include the Roman Catholic church of St Suitbert's, the Reformed church in the cemetery, the royal engineering school, a hospital; and there are monuments to Moltke, Bismarck (1897), and the Emperors William I. and Frederick III. There are, further, zoological gardens, and deaf and dumb and lunatic asylums. A railway 9 miles in length, with 20 stations, on the Langen mono-rail system, suspended on the river Wupper from Elberfeld to Barmen, has recently been opened. The industries are on a scale of great magnitude; various iron and steel industries, paper, musical instruments, tobacco, and carpet manufacture, and brewing are important. Population (1885), 109,218; (1900), 156,503.

**Elbeuf,** a town in the arrondissement of Rouen, department of Seine Inférieure, France, 14 miles south-south-west of Rouen by rail. There is a large manufacture of woollen goods, the raw material being imported chiefly from Argentina (average about 4700 tons). Elbeuf is also an important entrepôt for German wools. There is a state school of manufactures for the training of practical managers and foremen. Port traffic on the Seine (1898), 58,663 tons. Population (1901), 19,050.

**Elbing,** a town of Prussia, province of West Prussia, 49 miles east-south-east from Danzig by rail and 5 miles from the Frisches Haff. The town-hall (1894) contains the historical museum. The Marienkirche (15th and 16th centuries) was restored in 1887. There is a monument of the war of 1870–71 (1887). Elbing is a place of rapidly growing industry, the principal branches being iron ship-building (one firm alone employing more than 3000 hands and doing work for the Imperial navy) and other iron industries, and cigar manufacture. There is a large trade in agricultural produce. Population (1900), 52,298.

**Elbing-Oberland Canal,** in the Prussian provinces of East and West Prussia, connecting Lake Drausen, and consequently the port of Elbing, with Lakes Geserich and Drewenz to the south—total distance, 110 miles. The width is $52\frac{1}{2}$ feet, the depth $4\frac{1}{4}$ feet; and the canal, which was made in 1845–60, cost £225,000. It consists of four inclined planes connected by three stretches of canal and shut off by five sluices, the altitude of the two lakes and their feeders being 338 feet above sea-level, and the altitude of Lake Drausen only $5\frac{1}{4}$ feet. Boats are drawn up the inclined planes on waggons, which are hauled up by machinery.

**Elche,** a town and railway station of Spain, in the province of Alicante, on the river Vinalapo. It has grown in importance, and there are now more than a million palm trees in the district, and 22,500 tons of dates are exported every year. Manufactures of oil, flour, soap, leather, alcohol, and esparto-grass rugs are prosperous industries. Population (1887), 23,847; (1897), 28,030.

**Elduayen, José de,** 1st MARQUIS DEL PAZO DE LA MERCED (1823–1898), Spanish politician, was born in Madrid, 22nd June 1823. He was educated in the capital, took the degree of civil engineer, and as such directed important works in Asturias and Galicia, entered the Cortes in 1856 as deputy for Vigo, and sat in all the parliaments until 1867 as member of the Union Liberal with Marshal O'Donnell. He attacked the Miraflores cabinet in 1864, and became under-secretary of the Home Office when Canovas was minister in 1865. He was made a councillor of state in 1866, and in 1868 assisted other members of the Union Liberal in preparing the revolution. In the Cortes of 1872 he took much part in financial debates. He accepted office as a member of the last Sagasta cabinet under King Amadeus. On the proclamation of the republic Elduayen very earnestly co-operated in the Alphonsist conspiracy, and endeavoured to induce the military and politicians to work together. He went abroad to meet and accompany the prince after the *pronunciamiento* of Marshal Campos, landed with him at Valencia, was made governor of Madrid, a marquis, grand cross of Charles III., and Minister for the Colonies in 1878. He accepted the portfolio of Foreign Affairs in the Canovas cabinet from 1883 to 1885, and was made a life senator. He always prided himself on having been one of the five members of the Cortes of 1870 who voted for Alphonso XII. when that parliament elected Amadeus of Savoy. He died at Madrid, 24th June 1898.

END OF THIRD VOLUME.

# A PARTIAL LIST OF THE CONTRIBUTORS

TO

# THE NEW VOLUMES

OF

# THE ENCYCLOPÆDIA BRITANNICA

## WITH THE INITIALS WHICH HAVE BEEN AFFIXED TO THEIR RESPECTIVE ARTICLES.

THE LIST OF CONTRIBUTORS here given is necessarily incomplete, inasmuch as the later Volumes are still in course of preparation, and all the Contributors have not yet been selected. On the other hand, the present List may contain a few names which ultimately will not appear in the final List of Contributors. Death or other cause may prevent certain writers who have undertaken the preparation of Articles from completing the contributions which they were to furnish. A full List, compiled when the final Volume goes to press, will be given later. The present List, however, includes the names of all those who have written signed Articles for the first Volume.

After the few words of description which accompany the names are given the initials of the different authors as they have been affixed to the Articles contributed by them.

The Publishers congratulate themselves that in this List of a thousand names are to be found not only the most famous scholars and writers of Great Britain, but of the whole world.

### A

**ABBE, Prof. Cleveland,** A.M., Ph.D., LL.D.; Meteorologist, U.S. Weather Bureau; author of 'Atmospheric Radiation,' etc.; editor of 'Monthly Weather Review'; Lecturer on Meteorology, Johns Hopkins University. (C. A.)

**ABBOT, Rev. Lyman,** D.D.; editor of 'The Outlook' (New York); associate editor of 'The Christian Union' (New York) with Henry Ward Beecher, whom he succeeded as pastor of Plymouth Church, Brooklyn; author of 'Christianity and Social Problems,' 'Life of Christ,' 'Theology of an Evolutionist,' 'Life and Epistles of St Paul.' (L. A.)

**ABNEY, Sir William de Wiveleslie,** K.C.B., D.Sc., D.C.L., F.R.S.; Principal Assist. Sec., Board of Education, South Kensington, since 1899; President, Royal Astronomical Society, 1893-95; President, Physical Society, 1895-97; author of 'Photography' in Ninth Edition of the 'Ency. Brit.,' 'Instruction in Photography,' 'Treatise on Photography,' 'Colour Vision,' 'Colour-Measurement and Mixture,' 'Thebes and its Five Great Temples,' in part of 'The Pioneers of the Alps.' (W. DE W. A.)

**ADAMS, B. B.;** associate-editor of the 'Railroad Gazette' (New York). (B. B. A.)

**AIRY, Wilfred,** B.A., M.I.C.E.; Examiner of Inspectors of Weights and Measures, Board of Trade; author of 'Levelling and Geodesy,' 'Weighing Machines,' etc. (W. AY.)

**AKERS, C. E.;** author of 'Argentine, Patagonian, and Chilian Sketches,' etc. (C. E. A.)

**DALBY, W. Ernest,** M.A., B.Sc., M.I.C.E., M.I.M.E., Assoc. M.I. Nav. Architects; Professor of Mechanical Engineering and Applied Mathematics, City and Guilds Technical College, Finsbury. (W. E. D.)

**DALE, T. F.;** author of 'The Game of Polo, part-editor of 'Riding and Polo.' (T. F. D.)

**DALL, Hon. William Healey,** A.M.; naturalist, U.S. National Museum; author of 'Alaska and its Resources,' 'Tribes of the Extreme North-west,' etc. (W. H. D.)

**DALLAS, J. M. M.;** late Secretary of the Edinburgh Draughts Club. (J. M. M. D.)

**DANNREUTHER, Edward,** Professor Royal Coll. Mus.; author of 'Musical Ornamentation,' 'Liszt's Études,' 'Richard Wagner.' (E. DA.)

**DARWIN, George Howard,** M.A., LL.D., D.Sc., F.R.S.; Plumian Professor of Astronomy and Experimental Philosophy, Cambridge; Fellow of Trin. Coll Camb.; author of 'Tides,' in Ninth Edition of 'Ency. Brit.' 'Reports to B.A on Harmonic Analysis of Tidal Observations,' 'Memoirs on the Effects of Tidal Friction on the Earth and on the Moon,' Phil. Trans. Roy. Soc., 'The Tides and Kindred Phenomena in the Solar System,' etc. (G. H. D.)

**DARWIN, Leonard, Major,** late R.E.; Intelligence Dept. War Office, 1885-90; served on several scientific expeditions, including Transit of Venus of 1874 and 1882; author of 'Bi-metallism.' (L. D.)

**DAVENPORT, Cyril James H.,** F.S.A.; British Museum; silver medal Society of Arts, 1900; binding editor to the Anglo-Saxon Review; author of 'The English Regalia,' 'Royal English Bookbindings,' 'Cantor Lectures on Decorative Bookbindings,' 'English Embroidered Bookbindings,' 'Life of T. Berthelet.' (C. D.)

**DAVEY of Fernhurst, Lord,** D.C.L., F.R.S.; Lord of Appeal in Ordinary; Solicitor-General, 1886; Lord Justice of Appeal, 1893. (D.)

**DAVIDS, T. W. Rhys,** LL.D., Ph.D.; Secretary and Librarian Royal Asiatic Society; Professor of Pali and Buddhist Literature, Univ. Coll. London; author of 'Buddhism,' 'Jains,' 'Lamaism,' in Ninth Edition of 'Ency. Brit.,' 'Buddhism,' 'Buddhist Birth Stories,' 'Buddhist Suttas from the Pali,' 'Hibbert Lectures,' 1881, etc. (T. W. R. D.)

**DAVIDSON, William Leslie,** M.A., LL.D.; Professor of Logic and Metaphysics, Aberdeen University; author of 'English Words Explained,' 'Theism as grounded in Human Nature,' 'A Philosophical Centenary: Reid and Campbell,' 'Christian Ethics.' (W. L. D.)

**DAVIES, A. Llewelyn,** B.A.; Barrister, Inner Temple; Assistant Reader in Common Law under the Council of Legal Education. (A. LL. D.)

**DAVIES, Henry Walford,** Mus. Doc. (Camb.), A.R.C.M. (Lond.); organist and director of the choir, Temple Church, London; formerly organist and choirmaster, St Anne's, Soho; teacher of counterpoint, R.C.M., 1895. (H. W. D.)

**DAVIS, John Patterson,** Ph.D., A.M.; assistant in History and Economics, University of Michigan, 1894-1895; now Attorney-at-Law, Nampa, Idaho; author of 'The Union Pacific Railway,' etc. (J. P. D.)

**DAVIS, William Morris,** Professor Physical Geography, Harvard University; author of 'Physical Geography' and numerous scientific publications. (W. M. D.)

**DAWKINS, William Boyd,** M.A., D.Sc., F.R.S., F.S.A., F.G.S., A.M.I.C.E.; Professor of Geol. and Palæontology in Owens College, Manchester; geologist on Geological Survey of Great Britain, 1861-69; author of 'Cave' in Ninth Edition of 'Ency. Brit.,' 'Cave Hunting,' 'Early Man in Britain,' 'British Pleistocene Mammalia.' (W. B. D.)

**DAWSON, George Mercer,** LL.D., F.R.S., the late; Director Geological Survey of Canada; Geologist and Naturalist to H.M. North American Boundary Commission, 1873-75; one of

H.M. Behring Sea Commissioners, 1891, and under the Behring Sea Joint Commission Agreement, 1892; author of numerous scientific and technical reports printed by the Canadian Government, and scientific and other papers. (G. M. D.)

**DAY, Lewis F.**; English Designer and Art Lecturer; Med. Paris Exhibition (1900); Examiner for Art, Board of Education; author of 'Windows—Stained and Painted Glass,' 'The Anatomy of Pattern,' 'The Distribution of Ornamental Design,' 'Nature in Ornament,' etc. (L. F. D.)

**DAYOT, Armand**; Inspector of Fine Arts, Ministry of Fine Arts, France; author of 'Un siècle d'art,' 'La Révolution Française, d'après des peintures, sculptures, etc.,' 'Les maîtres de la caricature Française au XIXe siècle,' etc. (A. DA.)

**DEACON, George Frederick,** M.I.M.E.; Member of Council of Institution of Civil Engineers, London; investigated schemes for water-supply of Liverpool; projected the Vyrnwy scheme; carried out part of it in conjunction with the late Thomas Hawksley; President Association of Municipal and County Engineers, 1878; President Engineering Section Sanitary Institute, 1894; President Mechanical Science Section, British Association, Toronto, 1897. (G. F. D.)

**DEANS, Richard Storry,** LL.B.; Barrister-at-Law, Gray's Inn. (R. S. D.)

**DENNING, W. F.,** F.R.A.S.; Gold Medal, R.A.S.; President Liverpool Ast. Society, 1877-78; author of 'Telescopic Work for Starlight Evenings,' 'The Great Meteoric Shower,' etc. (W. F. D.)

**DE VILLIERS, John Abraham J.**; British Museum. (J. A. J. DE V.)

**DE VINNE, Theodore Low,** printer and typographist, New York; head of the firm of Theodore L. de Vinne and Co.; author of 'Printers' Price List,' 'Invention of Printing,' 'Historic Types,' etc. (T. L. DE V.)

**DEWAR, James,** M.A., Hon. LL.D. (Glasgow, St Andrews, Edin.), D.Sc. (Victoria), F.R.S., F.R.S.Ed., F.I.C., F.C.S.; Professorial Fellow of Peterhouse, Camb.; Jacksonian Professor of Experimental Philosophy, Cambridge; Fullerian Professor of Chemistry, Royal Institution, London; Vice-President of the Royal Society; a Director of the Davy-Faraday Research Laboratory; President British Association for 1902; co-inventor with Sir Frederick Abel of cordite; late member of the Government Explosives Committee; author of 'Alum,' etc. in Ninth Edition of 'Ency. Brit.,' numerous papers contributed to the proceedings of the Royal Societies of London and Edinburgh, the Royal Institution, the British Association, the Chemical Society, etc. (J. DR.)

**DIBDIN, Charles,** F.R.G.S., A.V.I.; Knight of St John of Jerusalem in England; Hon. Corresponding Member of Institutions de Prévoyance, France; Secy. of the Royal National Lifeboat Institution, England; Hon. Secy. of the Civil Service Lifeboat Fund. (C. DI.)

**DIBDIN, Lewis Tonna,** K.C., D.C.L. (Durham), F.S.A.; author of 'Church Courts,' 'City Livery Companies,' 'Brewer's Endowment and Establishment,' 'Monasticism in England,' 'Hanson's Death Duties.' (L. T. D.)

**DICEY, Edward,** C.B., B.A.; editor of 'The Observer' (London), 1870-89; author of 'Rome in 1860,' 'Cavour,' 'The Morning Land,' 'England and Egypt,' 'Victor Emmanuel,' 'Bulgaria, the Peasant State,' 'The Story of the Khedivate,' etc. (E. D.)

**DICKEY, Rev. Charles A.,** D.D.; President of the Presbyterian Hospital in Philadelphia; Moderator of the General Assembly of the Presbyterian Church in the U.S., 1900. (C. A. D.)

**DICKSON, Henry Newton,** B.Sc., F.R.S.E., F.R.G.S.; late Vice-President Royal Meteorological Society; Lecturer in Physical Geography, Oxford; author of 'Meteorology: the Elements of Weather and Climate,' etc. (H. N. D.)

**DIXON, Capt. J. Whitly,** R.N.; conservator of the river Humber; late Staff Commander of the Medway Fleet Reserve; author of 'Mariner's Compass in an Iron Ship,' etc. (J. W. D.)

**DOBSON, George**; Petersburg; author of 'Russia's Railway Advance and Central Asia,' etc. (G. D.)

**DOBSON, Henry Austin,** Principal, H.M. Board of Trade, to 1901; author of 'Hogarth' in Ninth Edition of 'Ency. Brit.'; 'Proverbs in Porcelain,' 'Old-World Idylls,' 'At the Sign of the Lyre,' 'Collected Poems,' 'Thomas Bewick and his Pupils,' Lives of Fielding, Steele, Goldsmith, Horace Walpole, William Hogarth, 'Four Frenchwomen,' 'Eighteenth Century Vignettes,' 'A Paladin of Philanthropy,' etc. (A. D.)

**DODD, Lieut.-Col. John Richard,** M.B., F.R.C.S., R.A.M.C.; Medical Officer, Royal Arsenal, Woolwich. (J. R. D.)

**DOUGLAS, James,** LL.D.; member and Vice-President Am. Inst. of Mining Engineers; member Am. Philosoph. Soc., Am. Geolog. Soc., Society of Arts, London, etc.; formerly Professor of Chemistry, Morrin College, Quebec; author of 'Canadian Independence,' 'Imperial Federation and Annexation,' numerous technical articles and reports, etc. (J. DS.)

**DOUGLAS, Robert Kennaway,** Keeper of Oriental Printed Books and MSS. at the British Museum; Professor of Chinese, King's Coll. London; appointed China Consular Service, 1858; retired, and appointed assistant in charge of Chinese Library, British Museum, 1865; author of 'Canton,' 'China,' 'Jenghiz Khan,' 'Manchuria,' etc., in Ninth Edition of 'Ency. Brit.,' 'The Language and Literature of China,' 'Confucianism and Taoism,' 'China,' 'A Chinese Manual,' 'The Life of Li Hung-Chang,' 'China.' (R. K. D.)

**DOUGLASS, William Tregarthen,** M.I.C.E., M.I.M.E., M.I.E.E.; late Resident Engineer to the Trinity House; Con. Eng. to Govts. of W. Australia, N. S. Wales, Victoria, Cape of Good Hope, etc.; erected the Eddystone, Bishop Rock Lighthouses, etc.; author of 'The New Eddystone Lighthouse,' 'On the More Efficient Lighting of Estuaries and Rivers,' etc. (W. T. D.)

**DOWSON, J. Emerson,** M.I.C.E., M.I.M.E.; Inventor of the Dowson Gas Plant; part author of 'Tramways,' 'Decimal Coinage,' etc. etc. (J. E. DO.)

**DREYER, John Louis Emil,** Director Armagh Observatory; assist. Astronomer at Dublin University Observatory, 1878-82; author of 'Observatory,' 'Sextant,' 'Time,' 'Transit Circle,' in Ninth Edition 'Ency. Brit.,' 'Second Armagh Catalogue of 3300 Stars,' 1886, 'New General Catalogue of Nebulæ and Clusters of Stars,' 'Tycho Brahe'; co-editor 'Copernicus: an International Journal of Astronomy,' 1881-84. (J. L. E. D.)

**DRIESCH, Hans A. E.,** Ph.D. Jena; Stazione Zoologica, Naples; author of 'Analytical Theory of Organic Development,' 'Biology,' etc. (H. A. E. D.)

**DRIVER, Rev. Samuel Rolles,** D.D., D.Litt.; Regius Professor of Hebrew, and Canon of Christ Church, Oxford; member of Old Testament Revision Company; author of 'Isaiah,' 'Notes on the Hebrew Text of the Books of Samuel,' 'An Introduction to the Literature of the Old Testament,' various commentaries; joint-editor of the 'Holy Bible, with various renderings and readings from the best authorities,' 'A Hebrew and English Lexicon of the Old Testament.' (S. R. D.)

**DUFF, Rt. Hon. Sir Mountstuart Elphinstone Grant,** P.C., M.A., D.L., G.C.S.I., F.R.S.; Under-Secretary of State for India, 1868-74; Under-Secretary for the Colonies, 1880-81; Governor of Madras, 1881-86; Member of Senate University of London, 1891; President Royal Geographical Society, 1889-93; President Royal Historical Society, 1892-99; author of 'Miscellanies, Political and Literary,' 'Memoir of Sir H. S. Maine,' 'Ernest Renan,' 'Memoir of Lord de Tabley,' 'Notes from a Diary.' (M. G. D.)

**DUFFIELD, William Bartleet**; of the Inner Temple, Barrister-at-Law. (W. B. DU.)

**DU FIEF, J.**; Secrétaire, Société Royale Belge de Géographie, Bruxelles; author of 'Atlas du Belgique,' 'Les decouvertes maritimes des Portugais au XVe siècle,' 'Les Expeditions Belges au Katenga,' etc. (J. DU F.)

**DUNCAN, Louis,** Ph.D.; sometime President of the American Institute of Electrical Engineers, and Associate Professor of Electricity, Johns Hopkins University, Baltimore. (L. DU.)

**DUNCAN, P.**; Secretary's Department, Inland Revenue Office, London. (P. D.)

**DUNNING, William Archibald,** Ph.D.; Professor of History, Columbia University, New York; member of The American Historical Association; author of 'Essays in Reconstruction,' etc.; editor 'Political Science Quarterly.' (W. A. D.)

**DUTT, Romesh Chunder,** C.I.E.; Lecturer Indian History, Univ. Coll. London; Fellow of the Calcutta Univ.; Divisional Commissioner, 1894 and 1895, being the only native of India who attained that position in the last century; author of a series of historical and social novels in Bengali, and a translation of the Rig Veda and other Sanscrit religious works into that language; in English, 'Civilization in Ancient India,' 'Lays of Ancient India,' 'Maha-bharata,' condensed into English verse, 'Ramayana,' condensed into English verse, 'England and India, 1785-1885'; 'Famines in India.' (R. C. D.)

**DYER, Sir William Turner Thiselton-,** M.A., B.Sc., LL.D., Ph.D., K.C.M.G., C.M.G., C.I.E., F.R.S.; Director, Royal Gardens, Kew; Fellow, University of London, 1887-90; V.P.R.S. 1896-97; joint-author of 'Biology' in Ninth Edition of 'Ency. Brit.,' 'Flora of Middlesex,' edited English edition of Sachs' 'Text-book of Botany,' 'Flora Capensis,' etc. (W. T. T.-D.)

## E

**EARDLEY-WILMOT, Rear-Admiral Sydney M.,** R.N.; author of 'The British Navy, Past and Present,' 'The Next Naval War,' 'Our Flags: Their Origin, Use, and Traditions,' 'The Development of Navies during the Last Half Century,' etc. (S. M. E.-W.)

**EATON, Fred. A.**; Secretary to the Royal Academy, London; edited Thausing's 'Albert Durer: His Life and Works.' (F. A. E.)

**EDGINGTON, Charles,** M.A.; President Oxford University Speed Skating Club; holder since 1898 of the world's speed record for the hour (19 m. 348 yds.). (C. E.)

**EDGEWORTH, Francis Ysidro,** M.A.; D.C.L.; Professor of Political Economy, Oxford, Fellow of All Souls' Coll. Oxford; Fellow of King's Coll. London; editor of the 'Economic Journal'; author of 'Mathematical Psychics,' etc. (F. Y. E.)

**EDWARDS, William Seymour,** Attorney and Counsellor-at-law, U.S.A.; author of 'Coals and Cokes in West Virginia.' (W. S. E.)

**EGERTON, H. E.**; author of 'A Short History of British Colonial Policy,' 'Sir Stamford Raffles,' 'Essays on Christ's Hospital,' etc. (H. E. EG.)

**ELIOT, Charles William,** LL.D., D.C.L.; President of Harvard University; author of 'American Contributions to Civilization,' 'Educational Reform,' etc. (C. W. E.)

**ELIOT, Whately,** M.I.C.E.; conducted survey of the coast of New Zealand; late Engineer to Peterhead Harbour Board; Resident Engineer Eastham section of the Manchester Ship Canal; Superintendent Civil Engineer, Keyham Dockyard Extension, etc. (W. E.)

**ELLINGTON, E. B.,** M.I.C.E.; Member of the Council M.E.; Member of the Société des Ingénieurs Civils de France; Chief Engineer London and Liverpool Hydraulic Power Companies, etc.; inventor of numerous improvements in hydraulic machinery. (E. B. E.)

**ERNST, Gen. Oswald Herbert**; Brigadier-General U.S.A.; member of the U.S. Isthmian Canal Commission; Engineer in charge of Western River Improvements, 1878-86, and of Harbour Improvements on Texas Coast, 1886-89; Superintendent U.S. Military Academy, 1893-98; author of 'Manual of Practical Military Engineering,' etc. (O. H. E.)

**EVANS, Hon. Henry Clay**; U.S. Commissioner of Pensions, Washington. (H. C. E.)

**EVERETT, Commander Allan F.,** R.N.; Signal School, H.M.S. 'Victory,' Portsmouth. (A. F. E.)

**EVERETT, Joseph David,** M.A., D.C.L., D.Sc., F.R.S.; late Professor of Natural Philosophy, Queen's Coll. Belfast; Assist. to Professor of Mathematics, Glasgow, 1864-67; author of 'Centimètre-Gramme-Second System of Units,' English edition of 'Deschanel's Physics,' 'Elementary Text-Book of Physics,' 'Outlines of Natural Philosophy.' (J. D. E.)

**EWART, James Cossar,** M.D., F.R.S.; Regius Professor of Natural History, Edinburgh; Professor Natural History, Aberdeen, 1878-82; member Fishery Board for Scotland; author of 'The Locomotor System of the Echinoderms' (with the late G. J. Romanes), 'On the Progress of Fish Culture in America,' 'On Whitebait,' 'On the Preservation of Fish,' 'The Development of the Limbs of the Horse.' (J. C. E.)

**EWING, James Alfred,** M.A., B.Sc., F.R.S., M.I.C.E.; Professor of Mechanism and Applied Mechanics, Cambridge; Fellow of King's College, Cambridge; Professor of Mechanical Engineering at the Imperial University, Tokyo, Japan, 1878-83; author of 'Pneumatic Despatch,' 'Seismometer,' 'Sewerage,' 'Siemens,' 'Steam Engine,' 'Strength of Materials' in Ninth Edition of 'Ency. Brit.,' 'Treatise on Earthquake Measurement,' 'Magnetic Induction in Iron and other Metals,' 'The Steam Engine and other Heat Engines,' etc. (J. A. E.)

**EXETER, Bishop of, Right Rev. Herbert Edward Ryle,** D.D., B.A.; Warburton Lecturer 1899-1903; Fellow King's College, Cambridge, 1881; Divinity Lecturer at

Emmanuel College, Cambridge, 1881-84; at King's College, 1882-86; Principal of St David's College, Lampeter, 1886-88; Professorial Fellow of King's College, Cambridge, 1888; examining chaplain to late Bishop of St Asaph, 1887-89, and to Bishop of Ripon, 1889; Hon. Canon of Ripon, 1895; Chaplain to the Queen, 1898-1901; Hulsean Professor of Divinity, Cambridge University, 1887-1901, and President of Queens' College, Cambridge, 1896-1901; author of 'The Canon of the Old Testament,' 'The Early Narratives of Genesis,' 'Commentary on Ezra and Nehemiah,' 'Philo and Holy Scripture,' etc. (H. E. R.)

## F

**FAIRBAIRN, Andrew Martin,** M.A., D.D., LL.D.; Principal Mansfield Coll. Oxford; Principal of Airedale Coll. 1877-1886; Chairman of Congregational Union of England and Wales, 1883; Member of Royal Commission on Secondary Education, 1894-95; author of 'Arminius,' 'Independents,' in Ninth Edition of 'Ency. Brit.,' 'Studies in the Life of Christ,' 'The City of God,' 'Religion in History and in Modern Life,' 'Catholicism, Roman and Anglican,' 'The Philosophy of the Christian Religion,' etc. (A. M. F.)

**FAIRBROTHER, William Henry,** M.A., Lecturer in Philosophy, Lincoln College, Oxford; author of 'Philosophy of Thomas Hill Green.' (W. H. F$^x$.)

**FAIRLIE, John A.,** Ph.D.; Asst. Prof. of Administrative Law, Univ. of Michigan; author of 'Municipal Government.' (J. A. Fa.)

**FARMER, John Bretland,** M.A., F.R.S.; Professor of Botany, Royal College of Science, London; Demonstrator of Botany, University of Oxford, 1887-92; Fellow of Magdalen College, Oxford, 1889; Assistant Professor of Biology, 1892-95; author of 'Memoirs, chiefly Botanical and Cytological.' (J. B. F.)

**FARRAR, Very Rev. Frederic William,** D.D., F.R.S.; Dean of Canterbury; Hulsean Lecturer at Cambridge; Bampton Lecturer at Oxford; Chaplain to the Speaker of the House of Commons, 1890-95; author of 'Jesus Christ' in Ninth Edition of 'Ency. Brit.,' 'The Life of Christ,' 'The Life of St Paul,' 'The Early Days of Christianity,' 'Darkness and Dawn,' 'The Bible, its Meaning and Supremacy,' etc. (F. W. F.)

**FAUNCE, W. H. P.,** A.M., D.D.; President of Brown University, Providence, R.I. (W. H. P. F.)

**FAUR, G.,** of the Egyptian Hall, London. (G. Fa.)

**FERGUSON, J.;** editor of the 'Ceylon Observer,' 'Tropical Agriculturist,' etc.; author of 'Handbook to Ceylon,' manuals on Coffee, Tea, Gold, Gems, etc. (J. F.)

**FERRERO, Baron Augusto;** editor of 'La Tribuna,' Rome; author of 'Nostalgie d'Amore'; edited 'From Florence to Rome: A Political Diary of 1870-71,' etc. (A. Fe.)

**FFOULKES, Miss C. Jocelyn;** translator of Morelli's 'Italian Painters,' etc. (C. J. F.)

**FIDLER, H.;** Civil Engineer, head of Technical Staff Department of Civil Engineer-in-Chief, Admiralty; editor of 'A Manual of Construction,' etc. (H. F.)

**FIELD, Capt. A. Mostyn,** R.N.; F.R.A.S., F.R.G.S., F.R.Met.S.; has worked for the Hydrographic Survey in various parts of the world. (A. M. F*.)

**FILON, Pierre Marie Augustin;** agrégé ès lettres; French Critic; tutor to the late Prince Imperial; literary editor of the 'Revue Bleue'; author of 'Le Mariage de Londres,' 'Histoire de la Littérature Anglais,' 'English Profiles,' and works on the French and English drama. (A. Fi.)

**FISHER, Alexander;** English teacher and specialist in the art of enamelling; author of technical articles in the 'Magazine of Art,' the 'Studio,' etc. (A. Fi*.)

**FISHER, George Park,** D.D., LL.D.; Professor of Ecclesiastical History, Yale; author of 'The Reformation,' 'History of the Christian Church,' 'The Colonial Era,' etc. (G. P. F.)

**FISKE, John,** LL.D., the late; author of 'Discovery of America,' 'American Revolution,' 'The Mississippi Valley in the Civil War,' 'Cosmic Philosophy,' etc. (J. Fi.)

**FITCH, Charles H.,** in charge of the Indian Territory Section, U.S. Geological Survey. (C. H. F.)

**FITCH, Sir Joshua Girling,** M.A., LL.D.: Chief Inspector of Training Colleges, retired 1894; H.M. Inspector of Schools, 1863; Chevalier of the Legion of Honour; Governor of St Paul's School, London, and Girton College, Cambridge; author of 'Lectures on Teaching,' 'The Arnolds and their Influence on English Education,' 'Educational Aims and Methods.' (J. G. F.)

**FITZGERALD, Vice-Adml. Charles Cooper Penrose;** Superintendent, Pembroke Dockyard; second in command of the China Station, 1898-1899; author of 'Boat Sailing,' 'Life of Sir George Tryon.' (C. C. P. F.)

**FITZGERALD, J. D.** (J. D. F.)

**FITZMAURICE-KELLY, James;** corresponding member of the Spanish Academy; author of 'A History of Spanish Literature,' 'The Life of Miguel de Cervantes Saavedra,' etc. (J. F.-K.)

**FLEMING, C. J. N.,** B.A.; Scottish International Football Player; member of Committee of Scottish Rugby Football Union. (C. J. N. F.)

**FLEMING, John Ambrose,** M.A., D.Sc., F.R.S.; Pender Professor of Electrical Engineering, Univ. College, London; Fellow of Univ. Coll. London; author of 'Treatise on the Alternate Current Transformer,' 'Electric Lamps and Electric Lighting,' 'Magnets and Electric Currents,' 'A Handbook for the Electrical Laboratory and Testing Room.' (J. A. F.)

**FOOTE, Arthur De Wint;** Superintendent of North Star Mining Company, California; Member of the American Society of Civil Engineers. (A. De W. F.)

**FORBES, Dr H. O.,** LL.D., F.R.G.S.; Director of Museums, Liverpool; author of 'A Naturalist's Wanderings in the Eastern Archipelago,' etc. (H. O. F.)

**FORD, Worthington Chauncey,** Public Library, Boston, U.S.A.; Chief of Bureau of Statistics, U.S. Department of State, 1885-89, and of Bureau of Statistics, U.S. Treasury Department, 1893-98; author of 'American Citizen's Manual,' etc. (W. C. F.)

**FORD, W. J.,** M.A.; author of 'A Cricketer on Cricket.' (W. J. F.)

**FORTIER, Alcée,** Litt.D.; Professor of Romance Language, Tulane University, New Orleans; sometime President of the Modern Language Association of America, and of the American Folk-Lore Society; President of the Louisiana Historical Society since 1894; author of 'Louisiana Studies,' 'Louisiana Folk Tales,' etc. (A. Fo.)

**FOSTER, Clement Le Neve,** B.A., D.Sc., F.R.S.; Professor of Mining at Royal School of Mines, London; Examiner in Mining for the Board of Education; Geological Survey of Great Britain, 1860-65; H.M. Inspector of Mines, 1873-1901; author of 'Mining' in Ninth Edition of 'Ency. Brit.,' 'Ore and Stone Mining,' etc. (C. L. N. F.)

**FOSTER, Hon. John Watson,** LL.D.; ex-U.S. Minister to Mexico, Russia, and Spain; U.S. Secretary of State 1892-93, and Agent of the United States in the Behring Sea Arbitration. (J. W. Fo.)

**FOSTER, Sir Michael,** D.C.L., D.Sc., LL.D., K.C.B., F.R.S., M.P.; Professor of Physiology, Cambridge; secretary R.S.; President British Ass., 1899; author of 'Physiology' in Ninth Edition of 'Ency. Brit.,' 'Text-Book of Physiology,' 'Lectures on History of Physiology'; joint-editor of 'Scientific Memoirs of Thomas Henry Huxley,' etc. (M. F.)

**FOWLER, G. H.,** Ph.D. Leipsic; late Hon. Secretary, Marine Biological Association, Plymouth; edited 'The Hydromedusa,' and 'The Leptomedusa,' Marshall's 'The Frog,' Erichson's 'Scientific Progress in Entomology.' (G. H. Fo.)

**FOX, Francis,** M.I.C.E.; author of 'On the Results of Trials of Varieties of Iron Permanent Way,' and various papers on 'Ventilation, Tunnelling,' etc. (F. Fo.)

**FOX, Major;** head of London Salvage Corps. (F. J. F.)

**FRANKLIN, Fabian,** Ph.D.; editor of 'Baltimore News,' Baltimore, U.S.A.; formerly Professor of Mathematics, Johns Hopkins University. (F. Fr.)

**FRANTZ, Henri;** art critic, 'Gazette des Beaux Arts,' Paris. (H. Fr.)

**FREAM, William,** LL.D., F.G.S. F.L.S., F.S.S.; Lecturer on Agricultural Entomology, Edin. Univ.; author of 'Elements of Agriculture,' 'Soils and their Properties,' 'The Complete Grazier,' etc. (W. Fr.)

**FREEMANTLE, Commander S.,** R.N.; part author of 'Nautical Terms and Phrases in French and English,' etc. (S. Fr.)

**FRERE, Rev. Walter Howard,** M.A.; Superior of the Community of the Resurrection; author of 'A New History of the Book of Common Prayer,' 'Notes on the Early History of the Use of Incense'; editor 'Bibliotheca Musico-Liturgica,' 'The Marian Reaction,' etc. (W. H. F.)

**FRY, Rt. Hon. Sir Edward,** B.A., D.C.L., LL.D., F.R.S., F.S.A., F.L.S.; Judge of High Court, Chancery Division, 1877-83; Lord Justice of Appeal, 1883-92; Fellow University of London and Univ. Coll. London; Hon. Fellow of Balliol Coll. Oxford; presided over the Royal Commission on the Irish Land Acts, 1897-98; author of 'Quakers' in Ninth Edition of 'Ency. Brit.,' 'The Specific Performance of Contracts,' 'British Mosses,' 'James Hack Tuke,' etc. (E. F.)

**FULTON, Robert Burwell,** A.M., LL.D.; Chancellor of the University of Mississippi; author of 'Mississippi, State' in Ninth Edition of 'Ency. Brit.' (R. B. F.)

## G

**GADOW, Hans Friedrich,** Ph.D., Hon. M.A. Cambridge, F.R.S.; Strickland Curator and Lecturer on Zoology, Cambridge; British Museum, Natural History Department, 1880-82; author of 'In Northern Spain,' 'A Classification of Vertebrata,' 'Aves in Bronn's Animal Kingdom,' 'Amphibia and Reptiles,' and papers in Royal Society Philosophical Transactions and other scientific periodicals. (H. F. G.)

**GALLWEY, Lt.-Col. Henry Lionel,** C.M.G, D.S.O.; Deputy Commissioner and Consul, Niger Coast Protectorate; Acting Consul-General, 1896-98, Oil Rivers Protectorate; in command of a Haussa company during operations in Benin country, including capture of Benin City, 1897, etc. (H. L. G.)

**GAMBLE, F. W.,** editor of 'Junior Course of Practical Zoology,' 'Flatworms and Mesozoa,' etc. (F. W. Ga.)

**GANNETT, Henry;** Chief Geographer U.S. Geological Survey; Chief Geographer 10th, 11th, and 12th U.S. Censuses; author of 'Idaho,' etc., in Ninth Edition of 'Ency. Brit.,' 'Dictionary of Altitudes,' 'Statistical Atlas of the U.S.,' etc. (H. G*.)

**GARCKE, Emile,** M.I.E.E., F.S.S.; Manager of the Brush Electrical Engineering Co.; Chairman Elect. Sect. London Chamber of Commerce, 1884-88; Member of Council, Tramways and Light Railways Assoc.; author of 'Manual of Electrical Undertakings,' joint-author of 'Factory Accounts.' (E. Ga.)
